
$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -32\mathbf{k} dt = c_1\mathbf{i} + c_2\mathbf{j} + (-32t + c_3)\mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{i} + \mathbf{j}$, $c_1 = 1$, $c_2 = 1$, and $c_3 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{\mathbf{i} + \mathbf{j} - 32t\mathbf{k}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{1 + 1 + 1024t} = \boxed{\sqrt{1024t + 2}}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int (\mathbf{i} + \mathbf{j} - 32t\mathbf{k}) dt = (t + d_1)\mathbf{i} + (t + d_2)\mathbf{j} + (-16t^2 + d_3)\mathbf{k}.$$

Since $\mathbf{r}(0) = \mathbf{0}$, $d_1 = 0$, $d_2 = 0$, and $d_3 = 0$, the position vector is given by

$$\mathbf{r}(t) = \boxed{t\mathbf{i} + t\mathbf{j} - 16t^2\mathbf{k}}.$$

19. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int (\cos t\mathbf{i} + \sin t\mathbf{j}) dt = (\sin t + c_1)\mathbf{i} + (-\cos t + c_2)\mathbf{j} + c_3\mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{i}$, $c_1 = 1$, $c_2 = 1$, and $c_3 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{(\sin t + 1)\mathbf{i} + (1 - \cos t)\mathbf{j}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{(\sin t + 1)^2 + (1 - \cos t)^2} = \sqrt{\sin^2 t + 2\sin t + 1 + 1 - 2\cos t + \cos^2 t} = \boxed{\sqrt{2\sin t - 2\cos t + 3}}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int [(\sin t + 1)\mathbf{i} + (1 - \cos t)\mathbf{j}] dt = (-\cos t + t + d_1)\mathbf{i} + (t - \sin t + d_2)\mathbf{j} + d_3\mathbf{k}.$$

Since $\mathbf{r}(0) = \mathbf{j}$, $d_1 = 1$, $d_2 = 1$, and $d_3 = 0$, the position vector is given by

$$\mathbf{r}(t) = \boxed{(t - \cos t + 1)\mathbf{i} + (t - \sin t + 1)\mathbf{j}}.$$

20. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int (\cos t \mathbf{i} + \sin t \mathbf{j}) dt = (\sin t + c_1) \mathbf{i} + (-\cos t + c_2) \mathbf{j} + c_3 \mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{j}$, $c_1 = 0$, $c_2 = 2$, and $c_3 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{\sin t \mathbf{i} + (2 - \cos t) \mathbf{j}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{\sin^2 t + (2 - \cos t)^2} = \sqrt{\sin^2 t + 4 - 4 \cos t + \cos^2 t} = \boxed{\sqrt{5 - 4 \cos t}}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int [\sin t \mathbf{i} + (2 - \cos t) \mathbf{j}] dt = (-\cos t + d_1) \mathbf{i} + (2t - \sin t + d_2) \mathbf{j} + d_3 \mathbf{k}.$$

Since $\mathbf{r}(0) = \mathbf{i}$, $d_1 = 2$, $d_2 = 0$, and $d_3 = 0$, the position vector is given by

$$\mathbf{r}(t) = \boxed{(2 - \cos t) \mathbf{i} + (2t - \sin t) \mathbf{j}}.$$

21. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -9.8 \mathbf{k} dt = c_1 \mathbf{i} + c_2 \mathbf{j} + (-9.8t + c_3) \mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{i}$, $c_1 = 1$, $c_2 = 0$, and $c_3 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{\mathbf{i} - 9.8t \mathbf{k}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{1 + (-9.8t)^2} = \boxed{\sqrt{96.04t^2 + 1}}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int (\mathbf{i} - 9.8t \mathbf{k}) dt = (t + d_1) \mathbf{i} + d_2 \mathbf{j} + (-4.9t^2 + d_3) \mathbf{k}.$$

Since $\mathbf{r}(0) = 5 \mathbf{k}$, $d_1 = 0$, $d_2 = 0$, and $d_3 = 5$, the position vector is given by

$$\mathbf{r}(t) = \boxed{t \mathbf{i} + (-4.9t^2 + 5) \mathbf{k}}.$$

22. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -9.8 \mathbf{k} dt = c_1 \mathbf{i} + c_2 \mathbf{j} + (-9.8t + c_3) \mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{i} + \mathbf{j}$, $c_1 = 1$, $c_2 = 1$, and $c_3 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{\mathbf{i} + \mathbf{j} - 9.8t \mathbf{k}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{1 + 1 + (-9.8t)^2} = \boxed{\sqrt{96.04t^2 + 2}}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int (\mathbf{i} + \mathbf{j} - 9.8t \mathbf{k}) dt = (t + d_1) \mathbf{i} + (t + d_2) \mathbf{j} + (-4.9t^2 + d_3) \mathbf{k}.$$

Since $\mathbf{r}(0) = 2 \mathbf{i}$, $d_1 = 2$, $d_2 = 0$, and $d_3 = 0$, the position vector is given by

$$\mathbf{r}(t) = \boxed{(t + 2) \mathbf{i} + t \mathbf{j} - 4.9t^2 \mathbf{k}}.$$

23. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int (e^{-t}\mathbf{i} + \mathbf{j}) dt = (-e^{-t} + c_1)\mathbf{i} + (t + c_2)\mathbf{j} + c_3\mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{i} + \mathbf{j}$, $c_1 = 2$, $c_2 = 1$, and $c_3 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{(-e^{-t} + 2)\mathbf{i} + (t + 1)\mathbf{j}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{(-e^{-t} + 2)^2 + (t + 1)^2} = \sqrt{e^{-2t} - 4e^{-t} + 4 + t^2 + 2t + 1} = \boxed{\sqrt{e^{-2t} - 4e^{-t} + t^2 + 2t + 5}}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int [(-e^{-t} + 2)\mathbf{i} + (t + 1)\mathbf{j}] dt = (e^{-t} + 2t + d_1)\mathbf{i} + \left(\frac{1}{2}t^2 + t + d_2\right)\mathbf{j} + d_3\mathbf{k}.$$

Since $\mathbf{r}(0) = \mathbf{i} - \mathbf{j}$, $d_1 = 0$, $d_2 = -1$, and $d_3 = 0$, the position vector is given by

$$\mathbf{r}(t) = \boxed{(e^{-t} + 2t)\mathbf{i} + \left(\frac{1}{2}t^2 + t - 1\right)\mathbf{j}}.$$

24. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int (t^2\mathbf{i} - e^{-t}\mathbf{k}) dt = \left(\frac{1}{3}t^3 + c_1\right)\mathbf{i} + c_2\mathbf{j} + (e^{-t} + c_3)\mathbf{k}.$$

Since $\mathbf{v}(0) = \mathbf{i} - \mathbf{j}$, $c_1 = 1$, $c_2 = -1$, and $c_3 = -1$, the velocity vector is

$$\mathbf{v}(t) = \boxed{\left(\frac{1}{3}t^3 + 1\right)\mathbf{i} - \mathbf{j} + (e^{-t} - 1)\mathbf{k}}$$

and the speed is

$$\begin{aligned} v = \|\mathbf{v}(t)\| &= \sqrt{\left(\frac{1}{3}t^3 + 1\right)^2 + 1 + (e^{-t} - 1)^2} = \sqrt{\frac{1}{9}t^6 + \frac{2}{3}t^3 + 1 + 1 + e^{-2t} - 2e^{-t} + 1} \\ &= \boxed{\sqrt{\frac{1}{9}t^6 + \frac{2}{3}t^3 + e^{-2t} - 2e^{-t} + 3}}. \end{aligned}$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int \left[\left(\frac{1}{3}t^3 + 1\right)\mathbf{i} - \mathbf{j} + (e^{-t} - 1)\mathbf{k}\right] dt = \left(\frac{1}{12}t^4 + t + d_1\right)\mathbf{i} + (-t + d_2)\mathbf{j} + (-e^{-t} - t + d_3)\mathbf{k}.$$

Since $\mathbf{r}(0) = \mathbf{k}$, $d_1 = 0$, $d_2 = 0$, and $d_3 = 2$, the position vector is given by

$$\mathbf{r}(t) = \boxed{\left(\frac{1}{12}t^4 + t\right)\mathbf{i} - t\mathbf{j} + (-e^{-t} - t + 2)\mathbf{k}}.$$

Applications and Extensions

25. Since $\mathbf{r}(0) = \mathbf{0}$ and the projectile has a constant initial velocity, we can use the formulas derived in the section. We are given that $v_0 = 520\text{m/s}$ and that $\theta = 30^\circ = \frac{\pi}{6}$ radians. The range is

$$x = \frac{v_0^2 \sin(2\theta)}{g} = \frac{520^2 \sin\left(\frac{\pi}{3}\right)}{9.8} \approx \boxed{23,895 \text{ m}},$$

the time in flight is

$$t = \frac{2v_0 \sin \theta}{g} = \frac{(2)(520) \sin\left(\frac{\pi}{6}\right)}{9.8} \approx \boxed{53 \text{ s}},$$

and the greatest height reached is

$$y = \frac{v_0^2 \sin^2 \theta}{2g} = \frac{(520)^2 \sin^2\left(\frac{\pi}{6}\right)}{(2)(9.8)} \approx \boxed{3449 \text{ m}}.$$

26. Since $\mathbf{r}(0) = \mathbf{0}$ and the projectile has a constant initial velocity, we can use the formulas derived in the section. We are given that $v_0 = 200\text{m/s}$ and that $\theta = 60^\circ = \frac{\pi}{3}$ radians. The range is

$$x = \frac{v_0^2 \sin(2\theta)}{g} = \frac{200^2 \sin\left(\frac{2\pi}{3}\right)}{9.8} \approx \boxed{3535 \text{ m}},$$

the time in flight is

$$t = \frac{2v_0 \sin \theta}{g} = \frac{(2)(200) \sin\left(\frac{\pi}{3}\right)}{9.8} \approx \boxed{35 \text{ s}},$$

and the greatest height reached is

$$y = \frac{v_0^2 \sin^2 \theta}{2g} = \frac{(200)^2 \sin^2\left(\frac{\pi}{3}\right)}{(2)(9.8)} \approx \boxed{1531 \text{ m}}.$$

27. Since $\mathbf{r}(0) = \mathbf{0}$ and the projectile has a constant initial velocity, we can use the formulas derived in the section. We are given that $v_0 = 100\text{m/s}$ and that $\theta = \tan^{-1}\left(\frac{5}{12}\right)$.

(a) The parametric equations of the motion of the projectile are

$$\begin{aligned} x &= (v_0 \cos \theta)t = 100 \cos \left[\tan^{-1} \left(\frac{5}{12} \right) \right] t \\ y &= -\frac{1}{2}gt^2 + (v_0 \sin \theta)t = -4.9t^2 + 100 \sin \left[\tan^{-1} \left(\frac{5}{12} \right) \right] t \end{aligned}$$

To simplify the angles, refer to the figure below. The angle $\theta = \tan^{-1}\left(\frac{5}{12}\right)$ is labeled on the triangle. Using the relations $\sin \theta = \frac{\text{opposite}}{\text{hypotenuse}}$ and $\cos \theta = \frac{\text{adjacent}}{\text{hypotenuse}}$,

$$\begin{aligned} x &= 100 \left(\frac{12}{13} \right) t = \frac{1200}{13} t \\ y &= -4.9t^2 + 100 \left(\frac{5}{13} \right) t = -4.9t^2 + \frac{500}{13} t \end{aligned}$$

The parametric equations of the path of the projectile are $x = \frac{1200}{13}t, y = -4.9t^2 + \frac{500}{13}t$.

(b) Using the identity $\sin(2\theta) = 2 \sin \theta \cos \theta$, we find the range to be

$$\begin{aligned} x &= \frac{v_0^2 \sin(2\theta)}{g} = \frac{100^2(2) \sin \left[\tan^{-1} \left(\frac{5}{12} \right) \right] \cos \left[\tan^{-1} \left(\frac{5}{12} \right) \right]}{9.8} \\ &= \frac{100^2(2) \left(\frac{5}{13} \right) \left(\frac{12}{13} \right)}{9.8} \approx \boxed{724.6 \text{ m}}. \end{aligned}$$

(c) The projectile is in the air for

$$t = \frac{2v_0 \sin \theta}{g} = \frac{(2)(100) \sin \left[\tan^{-1} \left(\frac{5}{12} \right) \right]}{9.8} = \frac{(2)(100) \left(\frac{5}{13} \right)}{9.8} \approx \boxed{7.8 \text{ s}}.$$

(d) The trajectory of the projectile is shown below.

28. Since $\mathbf{r}(0) = \mathbf{0}$ and the projectile has a constant initial velocity, we can use the formulas derived in the section. We are given that $v_0 = 120\text{m/s}$ and that $\theta = \tan^{-1} \left(\frac{3}{4} \right)$.

(a) The parametric equations of the motion of the projectile are

$$\begin{aligned} x &= (v_0 \cos \theta)t = 120 \cos \left[\tan^{-1} \left(\frac{3}{4} \right) \right] t \\ y &= -\frac{1}{2}gt^2 + (v_0 \sin \theta)t = -4.9t^2 + 120 \sin \left[\tan^{-1} \left(\frac{3}{4} \right) \right] t \end{aligned}$$

To simplify the angles, refer to the figure below. The angle $\theta = \tan^{-1} \left(\frac{3}{4} \right)$ is labeled on the triangle. Using the relations $\sin \theta = \frac{\text{opposite}}{\text{hypotenuse}}$ and $\cos \theta = \frac{\text{adjacent}}{\text{hypotenuse}}$,

$$\begin{aligned} x &= 120 \left(\frac{4}{5} \right) t = 96t \\ y &= -4.9t^2 + 120 \left(\frac{3}{5} \right) t = -4.9t^2 + 72t \end{aligned}$$

The parametric equations of the path of the projectile are $x = 96t, y = -4.9t^2 + 72t$.

(b) Using the identity $\sin(2\theta) = 2 \sin \theta \cos \theta$, we find the range to be

$$\begin{aligned} x &= \frac{v_0^2 \sin(2\theta)}{g} = \frac{120^2 (2) \sin \left[\tan^{-1} \left(\frac{3}{4} \right) \right] \cos \left[\tan^{-1} \left(\frac{3}{4} \right) \right]}{9.8} \\ &= \frac{120^2 (2) \left(\frac{3}{5} \right) \left(\frac{4}{5} \right)}{9.8} \approx \boxed{1410.6 \text{ m}}. \end{aligned}$$

(c) The projectile is in the air for

$$t = \frac{2v_0 \sin \theta}{g} = \frac{(2)(120) \sin \left[\tan^{-1} \left(\frac{3}{4} \right) \right]}{9.8} = \frac{(2)(120) \left(\frac{3}{5} \right)}{9.8} \approx \boxed{14.7 \text{ s}}.$$

(d) The trajectory of the projectile is shown below.

29. The hill makes a $30^\circ = \frac{\pi}{6}$ radians angle to the horizontal, meaning that $\tan \left(\frac{\pi}{6} \right) = \frac{y}{x}$, or $y = x \tan \left(\frac{\pi}{6} \right) = \frac{\sqrt{3}}{3}x$. The equation for the hill is

$$y_{\text{hill}} = \frac{\sqrt{3}}{3}x.$$

Since $\mathbf{r}(0) = \mathbf{0}$ and the projectile has a constant initial velocity, we can use the formulas derived in the section.

The position vector of the projectile is given by

$$\begin{aligned}\mathbf{r}(t) &= (v_0 \cos \theta)t\mathbf{i} + \left(v_0 \sin \theta t - \frac{1}{2}gt^2\right)\mathbf{j} = 100\left(\frac{\sqrt{2}}{2}\right)\mathbf{i} + \left[100\left(\frac{\sqrt{2}}{2}\right) - 16t^2\right]\mathbf{j} \\ &= 50\sqrt{2}t\mathbf{i} + (-16t^2 + 50\sqrt{2}t)\mathbf{j}.\end{aligned}$$

The hill and the projectile intersect where $y_{\text{hill}} = y_{\text{projectile}}$, and both the equation for the hill and the equation for the projectile must be satisfied. We substitute the equations for the projectile into the equation for the hill.

$$\begin{aligned}-16t^2 + 50\sqrt{2}t &= \left(\frac{\sqrt{3}}{3}\right)(50\sqrt{2}t) \\ -48t^2 + 150\sqrt{2}t &= 50\sqrt{6}t \\ -24t^2 + 75\sqrt{2}t - 25\sqrt{6}t &= 0 \\ t(-24t + 75\sqrt{2} - 25\sqrt{6}) &= 0\end{aligned}$$

The projectile and the hill intersect at $t = 0$ and $t = \frac{25\sqrt{2}}{8} - \frac{25\sqrt{6}}{24} \approx 1.868$ s.

(a) To find the distance between the projectile's starting point and landing point, we evaluate

$$x(1.868) = 50\sqrt{2}(1.868) \approx 132.078 \text{ ft} \quad y(1.868) = -16(1.868)^2 + 50\sqrt{2}(1.868) \approx 76.255 \text{ ft}.$$

Using the Pythagorean Theorem, we find the distance traveled by the projectile to be

$$\sqrt{x^2 + y^2} \approx \sqrt{132.078^2 + 76.255^2} \approx \boxed{152.5 \text{ ft}}.$$

(b) The projectile is in the air for $\boxed{1.9 \text{ s}}$.

30. We know that $y_0 = 3$ m and that when $x = 30$ m, we want $y = 1$ m. Assuming the only other force that acts on the projectile is gravity, $\mathbf{a}(t) = -9.8\mathbf{j}$. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -9.8\mathbf{j} dt = v_x\mathbf{i} + (-9.8t + v_y)\mathbf{j}$$

Because the projectile is being propelled horizontally, $\mathbf{v}(0) = v_0$, so $v_x = v_0$ and $v_y = 0$. The velocity vector is

$$\mathbf{v}(t) = v_0\mathbf{i} - 9.8t\mathbf{j}.$$

The position vector of the projectile is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int (v_0\mathbf{i} - 9.8t\mathbf{j}) dt = (v_0t + r_x)\mathbf{i} + (-4.9t^2 + r_y)\mathbf{j}.$$

Since $\mathbf{r}(0) = 3\mathbf{j}$, $r_x = 0$ and $r_y = 3$, the position vector is given by

$$\mathbf{r}(t) = v_0t\mathbf{i} + (-4.9t^2 + 3)\mathbf{j}.$$

At the time that the y -component is 1 m, we want the x -component to be 30 m. We now find the time at which that occurs. Solving $y = -4.9t^2 + 3 = 1$ gives $t \approx 0.639$ s. Substituting this time into the x -component allows us to solve for v_0 .

$$x = (v_0)(0.639) = 30 \quad \text{so} \quad v_0 \approx 47.0$$

The initial velocity of the projectile should be approximately $\boxed{47.0 \text{ m/s}}$.

31. We know $\mathbf{F} = m\mathbf{a}$, so $\|\mathbf{F}\| = \|m\mathbf{a}\| = m\|\mathbf{a}\|$, so $5 = (1)\|\mathbf{a}\|$ and $\|\mathbf{a}\| = 5$. The force acts in the direction of the positive x -axis, so $\theta = 0$, and the acceleration from the applied force is $5\mathbf{i}$. The acceleration is then $\mathbf{a}(t) = 5\mathbf{i} - 9.8\mathbf{j}$.

- (a) The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int (5\mathbf{i} - 9.8\mathbf{j}) dt = (5t + c_1)\mathbf{i} + (-9.8t + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = 3\mathbf{j}$, $c_1 = 0$ and $c_2 = 3$, the velocity vector is

$$\mathbf{v}(t) = \boxed{5t\mathbf{i} + (-9.8t + 3)\mathbf{j}}$$

and the speed is

$$v = \|\mathbf{v}(t)\| = \sqrt{(5t)^2 + (-9.8t + 3)^2} = \sqrt{25t^2 + 96.04t^2 - 58.8t + 9} = \boxed{\sqrt{121.04t^2 - 58.8t + 9}}.$$

- (b) The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int (5t\mathbf{i} + (-9.8t + 3)\mathbf{j}) dt = \left(\frac{5}{2}t^2 + d_1\right)\mathbf{i} + (-4.9t^2 + 3t + d_2)\mathbf{j}.$$

Since $\mathbf{r}(0) = \mathbf{0}$, $d_1 = 0$ and $d_2 = 0$, the position vector is given by

$$\mathbf{r}(t) = \boxed{\frac{5}{2}t^2\mathbf{i} + (-4.9t^2 + 3t)\mathbf{j}}.$$

- (c) The projectile is in the air until its y -component is zero, or when $-4.9t^2 + 3t = 0$. The projectile is in the air for $t \approx \boxed{0.612 \text{ s}}$.
- (d) The projectile has a parabolic shape. Because of the acceleration in the positive x -direction, the path of the projectile is stretched to the right.

32. Since $\mathbf{F} = \frac{\sqrt{2}m}{2}(-\mathbf{i} - \mathbf{j})$ and $\mathbf{F} = m\mathbf{a}$, $\mathbf{a} = \frac{\sqrt{2}m}{2}(-\mathbf{i} - \mathbf{j})$. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int \frac{\sqrt{2}m}{2}(-\mathbf{i} - \mathbf{j}) dt = \left(-\frac{\sqrt{2}}{2}t + c_1\right)\mathbf{i} + \left(-\frac{\sqrt{2}}{2}t + c_2\right)\mathbf{j}.$$

Since $\mathbf{v}(0) = 3\mathbf{i} + 4\mathbf{j}$, $c_1 = 3$ and $c_2 = 4$, the velocity vector is

$$\mathbf{v}(t) = \left(-\frac{\sqrt{2}}{2}t + 3\right)\mathbf{i} + \left(-\frac{\sqrt{2}}{2}t + 4\right)\mathbf{j}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int \left[\left(-\frac{\sqrt{2}}{2}t + 3 \right) \mathbf{i} + \left(-\frac{\sqrt{2}}{2}t + 4 \right) \mathbf{j} \right] dt = \left(-\frac{\sqrt{2}}{4}t^2 + 3t + d_1 \right) \mathbf{i} + \left(-\frac{\sqrt{2}}{4}t^2 + 4t + d_2 \right) \mathbf{j}.$$

Since $\mathbf{r}(0) = \mathbf{i} + 2\mathbf{j}$, $d_1 = 1$ and $d_2 = 2$, the position vector is given by

$$\mathbf{r}(t) = \left[\left(-\frac{\sqrt{2}}{4}t^2 + 3t + 1 \right) \mathbf{i} + \left(-\frac{\sqrt{2}}{4}t^2 + 4t + 2 \right) \mathbf{j} \right].$$

33. We begin with the acceleration due to gravity, $\mathbf{a}(t) = -32\mathbf{j}$, and integrate to first find the velocity vector and then the position vector. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -32\mathbf{j} dt = c_1\mathbf{i} + (-32t + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = v_0 \cos(45^\circ)\mathbf{i} + v_0 \sin(45^\circ)\mathbf{j}$, $c_1 = \frac{\sqrt{2}}{2}v_0$ and $c_2 = \frac{\sqrt{2}}{2}v_0$, the velocity vector is

$$\mathbf{v}(t) = \frac{\sqrt{2}}{2}v_0\mathbf{i} + \left(-32t + \frac{\sqrt{2}}{2}v_0 \right) \mathbf{j}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int \left[\frac{\sqrt{2}}{2}v_0\mathbf{i} + \left(-32t + \frac{\sqrt{2}}{2}v_0 \right) \mathbf{j} \right] dt = \left(\frac{\sqrt{2}}{2}v_0t + d_1 \right) \mathbf{i} + \left(-16t^2 + \frac{\sqrt{2}}{2}v_0t + d_2 \right) \mathbf{j}.$$

Since $\mathbf{r}(0) = 6.5\mathbf{j}$, $d_1 = 0$ and $d_2 = 6.5$, the position vector is given by

$$\mathbf{r}(t) = \left(\frac{\sqrt{2}}{2}v_0t \right) \mathbf{i} + \left(-16t^2 + \frac{\sqrt{2}}{2}v_0t + 6.5 \right) \mathbf{j}.$$

We will find the time t^* at which the ball lands in the basket. At t^* , $x(t^*) = 89.25$ ft and $y(t^*) = 10$ ft.

$$x(t^*) = \frac{\sqrt{2}}{2}v_0t^* = 89.25$$

$$y(t^*) = -16(t^*)^2 + \frac{\sqrt{2}}{2}v_0t^* + 6.5 = 10$$

so

$$t^* = \frac{89.25\sqrt{2}}{v_0}$$

and

$$y(t^*) = -16 \left[\frac{89.25\sqrt{2}}{v_0} \right]^2 + \frac{\sqrt{2}}{2}v_0 \left(\frac{89.25\sqrt{2}}{v_0} \right) + 6.5 = 10$$

$$v_0^2 = \frac{-16(89.25)^2(2)}{10 - 6.5 - 89.25}$$

$$v_0 \approx 54.521$$

The ball was tossed with initial velocity $\boxed{54.521 \text{ ft/s}}$.

34. We begin with the acceleration due to gravity, $\mathbf{a}(t) = -127008\mathbf{j}$, and integrate to first find the velocity vector and then the position vector. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -127008\mathbf{j} dt = c_1\mathbf{i} + (-127008t + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = 400\mathbf{i}$, $c_1 = 400$ and $c_2 = 0$, the velocity vector is

$$\mathbf{v}(t) = 400\mathbf{i} - 127008t\mathbf{j}.$$

The position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int (400\mathbf{i} - 127008t\mathbf{j}) dt = (400t + d_1)\mathbf{i} + (-63504t^2 + d_2)\mathbf{j}.$$

Since $\mathbf{r}(0) = 4\mathbf{j}$, $d_1 = 0$ and $d_2 = 4$, the position vector is given by

$$\mathbf{r}(t) = 400t\mathbf{i} + (-63504t^2 + 4)\mathbf{j}.$$

We need $x(t^*) = T$ or $400t^* = T$. Then $\tan \alpha = \frac{4}{T} = \frac{4}{400t^*} = \frac{1}{100t^*}$. We also need $y(t^*) = 0$ or $4 - 63504(t^*)^2 = 0$, which means $t^* = \frac{1}{126}$ hr and

$$\tan \alpha = \frac{1}{100\left(\frac{1}{126}\right)}$$

or

$$\alpha = \tan^{-1}\left(\frac{63}{50}\right) \approx 0.8999 \text{ rad} \approx 51.6^\circ.$$

The angle of sight $\alpha \approx \boxed{51.6^\circ}$.

35. We begin with the acceleration due to gravity, $\mathbf{a}(t) = -32\mathbf{j}$, and integrate to first find the velocity vector and then the position vector. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -32\mathbf{j} dt = c_1\mathbf{i} + (-32t + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = v_0 \cos 45^\circ \mathbf{i} + v_0 \sin 45^\circ \mathbf{j} = \frac{\sqrt{2}}{2}v_0\mathbf{i} + \frac{\sqrt{2}}{2}v_0\mathbf{j}$, $c_1 = \frac{\sqrt{2}}{2}v_0$ and $c_2 = \frac{\sqrt{2}}{2}v_0$, the velocity vector is

$$\mathbf{v}(t) = \frac{\sqrt{2}}{2}v_0\mathbf{i} + \left(-32t + \frac{\sqrt{2}}{2}v_0\right)\mathbf{j}.$$

The position vector of the baseball is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int \left[\frac{\sqrt{2}}{2}v_0\mathbf{i} + \left(-32t + \frac{\sqrt{2}}{2}v_0\right)\mathbf{j} \right] dt = \left(\frac{\sqrt{2}}{2}v_0t + d_1\right)\mathbf{i} + \left(-16t^2 + \frac{\sqrt{2}}{2}v_0t + d_2\right)\mathbf{j}.$$

Since $\mathbf{r}(0) = 3\mathbf{j}$, $d_1 = 0$ and $d_2 = 3$, the position vector is given by

$$\mathbf{r}(t) = \frac{\sqrt{2}}{2}v_0t\mathbf{i} + \left(-16t^2 + \frac{\sqrt{2}}{2}v_0t + 3\right)\mathbf{j}.$$

At the time t^* that the ball reaches the vines, $x(t^*) = 400$ and $y(t^*) = 10$. Then $t^* = \frac{400\sqrt{2}}{v_0}$ and

$$-16\left(\frac{400\sqrt{2}}{v_0}\right)^2 + \frac{\sqrt{2}}{2}v_0\left(\frac{400\sqrt{2}}{v_0}\right) + 3 = 10$$

$$v_0 \approx 114.14.$$

The initial speed of the baseball was $\boxed{114 \text{ ft/s}}$. Substituting $v_0 = 114.14$ into the equation for t^* gives $t^* \approx 4.956$ s. It takes the ball $\boxed{5 \text{ s}}$ to reach the vines.

36. We begin with the acceleration due to gravity, $\mathbf{a}(t) = -32\mathbf{j}$, and integrate to first find the velocity vector and then the position vector. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -32\mathbf{j} dt = c_1\mathbf{i} + (-32t + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = 100 \cos 45^\circ \mathbf{i} + 100 \sin 45^\circ \mathbf{j} = 50\sqrt{2}\mathbf{i} + 50\sqrt{2}\mathbf{j}$, $c_1 = 50\sqrt{2}$ and $c_2 = 50\sqrt{2}$, the velocity vector is

$$\mathbf{v}(t) = 50\sqrt{2}\mathbf{i} + (-32t + 50\sqrt{2})\mathbf{j}.$$

The position vector of the baseball is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int [50\sqrt{2}\mathbf{i} + (-32t + 50\sqrt{2})\mathbf{j}] dt = (50\sqrt{2}t + d_1)\mathbf{i} + (-16t^2 + 50\sqrt{2}t + d_2)\mathbf{j}.$$

Since $\mathbf{r}(0) = 6\mathbf{j}$, $d_1 = 0$ and $d_2 = 6$, the position vector is given by

$$\mathbf{r}(t) = 50\sqrt{2}t\mathbf{i} + (-16t^2 + 50\sqrt{2}t + 6)\mathbf{j}.$$

- (a) The ball reaches home plate when $y(t^*) = -16(t^*)^2 + 50\sqrt{2}t^* + 6 = 0$ or $t^* \approx 4.5$. The maximum distance occurs at $x(t^*) = 50\sqrt{2}(4.5) \approx 318.4$. The furthest an outfielder can be from home plate to ensure that the ball reaches home plate on the fly is about $\boxed{318 \text{ ft}}$.
- (b) The ball is in flight for $\boxed{t^* \approx 4.5 \text{ s}}$.
- (c) If the distance from third place to home plate is 90 ft, the player must run at a speed of $\frac{90}{4.5} \approx \boxed{20 \text{ ft/s}}$.
37. Since $\mathbf{r}(0) = \mathbf{0}$ and the football has a constant initial velocity, we can use the formulas derived in the section.

- (a) The range is

$$x = \frac{v_0^2 \sin(2\theta)}{g} = \frac{(65^2) \sin(60^\circ)}{32} = \boxed{114.342 \text{ ft}}.$$

- (b) The position vector is

$$\begin{aligned} \mathbf{r}(t) &= (v_0 \cos \theta)t\mathbf{i} + \left[(v_0 \sin \theta)t - \frac{1}{2}gt^2\right]\mathbf{j} = 65 \cos(30^\circ)t\mathbf{i} + [65 \sin(30^\circ)t - 16t^2]\mathbf{j} \\ &= \frac{65\sqrt{3}}{2}t\mathbf{i} + \left(\frac{65}{2}t - 16t^2\right)\mathbf{j}. \end{aligned}$$

We want to find $x(t^*)$ for $y(t^*) = 10$.

$$\frac{65}{2}t^* - 16(t^*)^2 = 10$$

which means that $t^* \approx 0.378$ or $t^* \approx 1.65$. Since $x(t)$ is an increasing function of t for $t > 0$, $t^* \approx 1.65$ gives the maximum distance. The furthest from the goal post the kick can originate and score a field goal is

$$\frac{65\sqrt{3}}{2}(1.65) \approx \boxed{93 \text{ ft}}.$$

38. We will show that when the y -component of the projectile – its height – is the same as the y -component of the target, the x -component of the projectile is the same as the x -component of the target. Since the bullet begins at the origin and has a constant initial velocity, we can use the formulas derived in the section.

$$\mathbf{r}_{\text{projectile}} = (v_0 \cos \theta)t\mathbf{i} + \left(-\frac{1}{2}gt^2 + (v_0 \sin \theta)t\right)\mathbf{j}$$

The target has a constant x position and an initial height of T . We define the distance from the origin to the target which is the hypotenuse of the triangle in the figure as h . This makes the x -coordinate of the position $x_T = h \cos \theta_0$ and the y -coordinate of the position $y_T = h \sin \theta_0$. We begin with the acceleration due to gravity, $\mathbf{a}(t) = -g\mathbf{j}$, and integrate to first find the velocity vector and then the position vector. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -g\mathbf{j} dt = c_1\mathbf{i} + (-gt + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = \mathbf{0}$, the velocity vector is

$$\mathbf{v}(t) = -gt\mathbf{j}.$$

The position vector of the target is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int -gt dt = d_1\mathbf{i} + \left(-\frac{1}{2}gt^2 + d_2\right)\mathbf{j}.$$

Since $\mathbf{r}(0) = x_T\mathbf{i} + y_T\mathbf{j}$, $d_1 = x_T = h \cos \theta_0$ and $d_2 = y_T = h \sin \theta_0$, the position vector is given by

$$\mathbf{r}(t) = h \cos \theta_0 \mathbf{i} + \left(-\frac{1}{2}gt^2 + h \sin \theta_0\right)\mathbf{j}.$$

The time t^* when $y_{\text{projectile}} = y_T$ can be found.

$$\begin{aligned} y(t^*) &= -\frac{1}{2}g(t^*)^2 + h \sin \theta_0 = -\frac{1}{2}g(t^*)^2 + (v_0 \sin \theta_0)t^* \\ t^* &= \frac{h \sin \theta_0}{v_0 \sin \theta_0} = \frac{h}{v_0} \end{aligned}$$

We can now determine the x -position of the projectile at t^* .

$$x(t^*) = v_0 \cos \theta_0 \left(\frac{h}{v_0}\right) = h \cos \theta_0 = x_T$$

Since $x_{\text{projectile}}(t^*) = x_T$ when $y_{\text{projectile}}(t^*) = y_T$ and none of these expressions depend on v_0 , the bullet will always hit the falling target, no matter what the initial speed v_0 is. ■

39. If the position vector is $\mathbf{r}(t) = (v_0 \cos \theta)t\mathbf{i} + [(v_0 \sin \theta)t - \frac{1}{2}gt^2]\mathbf{j}$, then $\mathbf{r}(0) = \mathbf{0}$, and the range of the projectile is $\frac{(v_0)^2 \sin(2\theta)}{g}$.

- (a) This range will be maximized when $\sin(2\theta)$ is maximized or when $\sin(2\theta) = 1$. We know $\sin(2\theta) = 1$ when $2\theta = \frac{\pi}{2}$ or when $\theta = \frac{\pi}{4}$. Equivalently, we could see that the range is maximized by taking the derivative of the range function.

$$\frac{d}{d\theta}x(\theta) = \frac{d}{d\theta} \left[\frac{v_0^2 \sin(2\theta)}{g} \right] = \frac{v_0^2 \cos(2\theta)2}{g}$$

The critical points for the range are $\theta = 0$ and $\theta = \frac{\pi}{4}$. Since $x'(\theta)$ is positive for $0 < \theta < \frac{\pi}{4}$ and is negative for $\frac{\pi}{4} < \theta < \frac{\pi}{2}$, the maximum range occurs at $\theta = \frac{\pi}{4}$. ■

- (b) The maximum range occurs when $\theta = \frac{\pi}{4}$, so the maximum range is

$$\frac{v_0^2 \sin(2\theta)}{g} = \frac{v_0^2 \sin\left(\frac{\pi}{2}\right)}{g} = \frac{v_0^2}{g}.$$

■

40. If the position vector is $\mathbf{r}(t) = (v_0 \cos \theta)t\mathbf{i} + [(v_0 \sin \theta)t - \frac{1}{2}gt^2]\mathbf{j}$, then $\mathbf{r}(0) = \mathbf{0}$, so the maximum height of the projectile occurs at $t = \frac{v_0 \sin \theta}{g}$ and the velocity vector of the projectile is $\mathbf{v}(t) = v_0 \cos \theta \mathbf{i} + (v_0 \sin \theta - gt)\mathbf{j}$. The speed is then

$$v = \sqrt{v_0^2 \cos^2 \theta + v_0^2 \sin^2 \theta - 2v_0 \sin \theta gt + g^2 t^2} = \sqrt{v_0^2 - 2v_0 \sin \theta gt + g^2 t^2}.$$

To find the extrema of the speed, we look at the first derivative.

$$\frac{d}{dt}v = \frac{d}{dt}\sqrt{v_0^2 - 2v_0 \sin \theta gt + g^2 t^2} = \frac{1}{2}(v_0^2 - 2v_0 \sin \theta gt + g^2 t^2)^{-1/2}(-2v_0 \sin \theta g + 2g^2 t)$$

The critical point occurs when $-2v_0 \sin \theta g + 2g^2 t = 0$, or at $t = \frac{v_0 \sin \theta}{g}$. The derivative is negative for $0 < t < \frac{v_0 \sin \theta}{g}$ and positive for $t > \frac{v_0 \sin \theta}{g}$, so the minimum speed occurs at $t = \frac{v_0 \sin \theta}{g}$, which is when the maximum height of the projectile occurs. ■

41. If no outside forces are applied to the particle, then $\mathbf{F} = m\mathbf{a} = \mathbf{0}$, so $\mathbf{a} = \mathbf{0}$. Finding the velocity and position vectors,

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = c_1 \mathbf{i} + c_2 \mathbf{j}$$

and

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = (c_1 t + d_1)\mathbf{i} + (c_2 t + d_2)\mathbf{j}.$$

If $c_1 = c_2 = 0$, the particle is stationary. If either c_1 or c_2 is not zero, the position vector is the vector equation of a line, and its speed is $\|\mathbf{v}(t)\| = \sqrt{c_1^2 + c_2^2}$, which is a constant. Therefore, the particle is either stationary or moves with constant speed along a straight line. ■

42. If $\mathbf{r}'(t) = \mathbf{0}$ for all t on some interval I , then

$$\mathbf{r}(t) = \int \mathbf{r}'(t) dt = c_1 \mathbf{i} + c_2 \mathbf{j} = \mathbf{c}$$

for all t in I . ■

43. Let $\mathbf{f}'(t) = f'_1(t)\mathbf{i} + f'_2(t)\mathbf{j} + f'_3(t)\mathbf{k}$ and $\mathbf{g}'(t) = g'_1(t)\mathbf{i} + g'_2(t)\mathbf{j} + g'_3(t)\mathbf{k}$. If $\mathbf{f}'(t) = \mathbf{g}'(t)$ for all t in some interval I , then $f'_1(t) = g'_1(t)$, $f'_2(t) = g'_2(t)$, and $f'_3(t) = g'_3(t)$. From Section 4.8 we know that if $f'(x) = g'(x)$ for all numbers x in an interval (a, b) , then there exists a number C for which $f(x) = g(x) + C$ on (a, b) . Applied to this situation, that means that $f_1(t) = g_1(t) + c_1$, $f_2(t) = g_2(t) + c_2$, and $f_3(t) = g_3(t) + c_3$, or $\mathbf{f}(t) = \mathbf{g}(t) + \mathbf{c}$. ■

Challenge Problems

44. Let $\mathbf{c} = c_1 \mathbf{i} + c_2 \mathbf{j} + c_3 \mathbf{k}$ and $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$. Then

$$\begin{aligned} \int_a^b \mathbf{c} \cdot \mathbf{r}(t) dt &= \int_a^b [c_1 x(t) + c_2 y(t) + c_3 z(t)] dt = \int_a^b c_1 x(t) dt + \int_a^b c_2 y(t) dt + \int_a^b c_3 z(t) dt \\ &= c_1 \int_a^b x(t) dt + c_2 \int_a^b y(t) dt + c_3 \int_a^b z(t) dt = \mathbf{c} \cdot \int_a^b \mathbf{r}(t) dt. \end{aligned}$$

45. Let $\mathbf{c} = \int_a^b \mathbf{r}(t) dt$. Then

$$\|\mathbf{c}\|^2 = \mathbf{c} \cdot \mathbf{c} = \left| \int_a^b \mathbf{r}(s) ds \cdot \int_a^b \mathbf{r}(t) dt \right|.$$

Because $\int_a^b \mathbf{r}(s) ds$ is a constant with respect to the variable t , we can use the result from Problem 44 to bring it into the integral with respect to t .

$$\|\mathbf{c}\|^2 = \left| \int_a^b \left(\int_a^b \mathbf{r}(s) ds \right) \cdot \mathbf{r}(t) dt \right|$$

We can change the order of the terms in the dot product by commutativity, and then, since $\mathbf{r}(t)$ is a constant with respect to the variable s , we can bring $\mathbf{r}(t)$ into the integral with respect to s by using the result from Problem 44 again.

$$\|\mathbf{c}\|^2 = \left| \int_a^b \mathbf{r}(t) \cdot \left(\int_a^b \mathbf{r}(s) ds \right) dt \right| = \left| \int_a^b \left(\int_a^b \mathbf{r}(t) \cdot \mathbf{r}(s) ds \right) dt \right|$$

From problem 115 from section 5.4, we know that

$$\left| \int_a^b f(x) dx \right| \leq \int_a^b |f(x)| dx.$$

We use this result twice to obtain the following:

$$\begin{aligned} \|\mathbf{c}\|^2 &= \left| \int_a^b \left(\int_a^b \mathbf{r}(t) \cdot \mathbf{r}(s) ds \right) dt \right| \\ &\leq \int_a^b \left| \int_a^b \mathbf{r}(t) \cdot \mathbf{r}(s) ds \right| dt \\ &\leq \int_a^b \left(\int_a^b |\mathbf{r}(t) \cdot \mathbf{r}(s)| ds \right) dt \end{aligned}$$

We can use properties of the dot product to see that

$$\mathbf{r}(t) \cdot \mathbf{r}(s) = \|\mathbf{r}(t)\| \|\mathbf{r}(s)\| \cos \theta \leq \|\mathbf{r}(t)\| \|\mathbf{r}(s)\|,$$

which implies that

$$\begin{aligned} \|\mathbf{c}\|^2 &\leq \int_a^b \left(\int_a^b |\mathbf{r}(t) \cdot \mathbf{r}(s)| ds \right) dt \\ &\leq \int_a^b \left(\int_a^b \|\mathbf{r}(t)\| \|\mathbf{r}(s)\| ds \right) dt. \end{aligned}$$

Since $\|\mathbf{r}(t)\|$ is a constant with respect to the variable s , we can pull it out of the inner integral, rearrange the order, and simplify, obtaining

$$\begin{aligned} \|\mathbf{c}\|^2 &\leq \int_a^b \left(\int_a^b \|\mathbf{r}(t)\| \|\mathbf{r}(s)\| ds \right) dt \\ &= \int_a^b \|\mathbf{r}(t)\| \left(\int_a^b \|\mathbf{r}(s)\| ds \right) dt \\ &= \int_a^b \left(\int_a^b \|\mathbf{r}(s)\| ds \right) \|\mathbf{r}(t)\| dt. \end{aligned}$$

Finally, since $\int_a^b \|r(s)\| ds$ is a constant with respect to the variable t , we have

$$\begin{aligned}\|\mathbf{c}\|^2 &\leq \int_a^b \left(\int_a^b \|\mathbf{r}(s)\| ds \right) \|\mathbf{r}(t)\| dt \\ &= \left(\int_a^b \|\mathbf{r}(s)\| ds \right) \left(\int_a^b \|\mathbf{r}(t)\| dt \right) \\ &= \left(\int_a^b \|\mathbf{r}(t)\| dt \right) \left(\int_a^b \|\mathbf{r}(t)\| dt \right) \\ &= \left(\int_a^b \|\mathbf{r}(t)\| dt \right)^2.\end{aligned}$$

Since $\|\mathbf{c}\|^2 = \left\| \int_a^b \mathbf{r}(t) dt \right\|^2$, we have

$$\left\| \int_a^b \mathbf{r}(t) dt \right\|^2 \leq \left(\int_a^b \|\mathbf{r}(t)\| dt \right)^2$$

which, in turn, implies

$$\left\| \int_a^b \mathbf{r}(t) dt \right\| \leq \int_a^b \|\mathbf{r}(t)\| dt. \blacksquare$$

46. Let $\mathbf{c} = c_1\mathbf{i} + c_2\mathbf{j} + c_3\mathbf{k}$ and $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$. Then

$$\int_a^b \mathbf{c} \times \mathbf{r}(t) dt = \int_a^b ([c_2z(t) - c_3y(t)]\mathbf{i} - [c_1z(t) - c_3x(t)]\mathbf{j} + [c_1y(t) - c_2x(t)]\mathbf{k}) dt$$

We can rewrite the terms using properties of integrals.

$$\begin{aligned}\int_a^b [c_2z(t) - c_3y(t)]\mathbf{i} dt &= \left(c_2 \int_a^b z(t) dt - c_3 \int_a^b y(t) dt \right) \mathbf{i}, \\ \int_a^b -[c_1z(t) - c_3x(t)]\mathbf{j} dt &= - \left(c_1 \int_a^b z(t) dt - c_3 \int_a^b x(t) dt \right) \mathbf{j}, \\ \int_a^b [c_1y(t) - c_2x(t)]\mathbf{k} dt &= \left(c_1 \int_a^b y(t) dt - c_2 \int_a^b x(t) dt \right) \mathbf{k}\end{aligned}$$

Then

$$\int_a^b \mathbf{c} \times \mathbf{r}(t) dt = \mathbf{c} \times \int_a^b \mathbf{r}(t) dt. \quad \blacksquare$$

11.6 Application: Kepler's Laws of Planetary Motion

Applications and Extensions

- Kepler's Third Law says that the square of the period of revolution of a planet is proportional to the cube of the length of the semimajor axis of the planet's elliptical orbit. For a circular orbit, the semimajor axis is the radius, so for this planetary system, $(28.1 \text{ days})^2 = k(1.8 \times 10^{10} \text{ m})^3$, where k is the constant of proportionality. Solving for k , we find that for this system, $k \approx 1.354 \times 10^{-28} \frac{\text{days}^2}{\text{m}^3}$. The second planet is twice as far from the central star, so the length of its radius is $3.6 \times 10^{10} \text{ m}$, which means that the square of the period of revolution of the second planet is approximately $1.354 \times 10^{-28} \frac{\text{days}^2}{\text{m}^3} \cdot (3.6 \times 10^{10} \text{ m})^3 = 6316.8800 \text{ days}^2$. The period of revolution of the other planet is $\boxed{79.479 \text{ days}}$.

- For this system, $(1.77 \text{ days})^2 = k(422000 \text{ km})^3$, so $k \approx 4.169 \times 10^{-17} \frac{\text{days}^2}{\text{km}^3}$.

- Let T_1 be the period of Europa and $d_1 = 671000 \text{ km}$ be the distance from Europa to Jupiter. Then

$$T_1^2 = k(671000 \text{ km})^3 \quad \text{so} \quad T_1^2 \approx 12.594 \text{ days}^2 \quad \text{and} \quad T_1 \approx \boxed{3.55 \text{ days}}.$$

- Let $T_2 = 7.16 \text{ days}$ be the period of Ganymede and d_2 be its distance from Jupiter. Then

$$(7.16 \text{ days})^2 = kd_2^3 \quad \text{so} \quad d_2^3 \approx 1.230 \times 10^{18} \text{ km}^3 \quad \text{and} \quad d_2 \approx \boxed{1.07 \times 10^6 \text{ km}}.$$

- Since $\mathbf{r} \times \mathbf{v}$ is a constant and perpendicular to both $\mathbf{r}$ and $\mathbf{v}$, $\mathbf{r}$ and $\mathbf{v}$ must be in a plane.
- Since $\frac{dA}{dt}$ is constant, a change in area is proportional to a change of time without regard to the actual time.

Challenge Problems

- (a) Since $\frac{dA}{dt} = \frac{1}{2}\|\mathbf{D}\|$ which is a constant,

$$\int_0^T \frac{dA}{dt} dt = \int_0^T \frac{1}{2}\|\mathbf{D}\| dt$$

and

$$A = \frac{1}{2}\|\mathbf{D}\|T.$$

For a circular orbit, $A = \pi\|\mathbf{r}\|^2$, so $T = \frac{2\pi\|\mathbf{r}\|^2}{\|\mathbf{D}\|}$. Given that $\|\mathbf{D}\|^2 = \|\mathbf{r}\|GM(1 + e \cos \theta)$ in the proof of Kepler's first law and that $e = 0$ for a circle,

$$T = \frac{2\pi\|\mathbf{r}\|^2}{\sqrt{\|\mathbf{r}\|GM}} \quad \text{and} \quad T^2 = \frac{4\pi^2\|\mathbf{r}\|^3}{GM},$$

which shows that the square of the period is proportional to the cube of the radius, which is the length of the semimajor axis for a circular orbit. ■

- Since the gravitational constant G is measured in $\text{N}\cdot\text{m}^2/\text{kg}^2$ and $\text{N} = \text{kg}\cdot\text{m}/\text{s}^2$, we must convert the period of the Earth from days into seconds.

$$365 \frac{\text{days}}{\text{year}} \cdot 24 \frac{\text{hours}}{\text{day}} \cdot 60 \frac{\text{min}}{\text{hr}} \cdot 60 \frac{\text{sec}}{\text{min}} = 3.1536 \times 10^7 \frac{\text{sec}}{\text{year}}$$

From part (a), $M = \frac{4\pi^2\|\mathbf{r}\|^3}{GT^2}$, so

$$M = \frac{4\pi^2(1.5 \times 10^{11})^3}{(6.67 \times 10^{-11})(3.1536 \times 10^7)^2} \approx \boxed{2.0 \times 10^{30} \text{ kg}}.$$

6. We are given

$$\|\mathbf{r}\| = \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1 + e \cos \theta} \right).$$

The length of the semimajor axis corresponds to half the sum of the $\|\mathbf{r}\|$ values at $\theta = 0$ and $\theta = \pi$.

$$\text{Length of the semimajor axis} = \frac{1}{2} \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1+e} + \frac{1}{1-e} \right) = \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1-e^2} \right).$$

The length of the semiminor axis corresponds to the height of a right triangle that has as its base the line segment going from the center of the ellipse to the focus at the origin and as its hypotenuse the line segment going from the top minor axis vertex to the origin. The length of the base is equal to $\|\mathbf{r}\|$ at $\theta = 0$ subtracted from the length of the semimajor axis. The length of the hypotenuse is equal to the length of the semimajor axis by definition of the ellipse. Using the Pythagorean Theorem we get

$$\text{Length of the semiminor axis} = \sqrt{\left[\frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1-e^2} \right) \right]^2 - \left[\frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1-e^2} \right) - \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1+e} \right) \right]^2} = \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{\sqrt{1-e^2}} \right).$$

The area of the ellipse is πab where a is the semimajor axis and b is the semiminor axis.

$$\text{Area of the ellipse} = \pi \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{1-e^2} \right) \frac{\|\mathbf{D}\|^2}{GM} \left(\frac{1}{\sqrt{1-e^2}} \right) = \frac{\pi \|\mathbf{D}\|^4}{G^2 M^2} \left[\frac{1}{(1-e^2)^{3/2}} \right].$$

7. (a) Problem 75 (e) in section 11.4 showed that the angular component of acceleration is $r\theta'' + 2r'\theta'$. Given that the force is directed toward the origin, the angular component must be equal to zero. Therefore, $r\theta'' + 2r'\theta' = 0$.
- (b) Multiply by r to get $r^2\theta'' + 2rr'\theta' = 0$. Note that this is equivalent to $\frac{d(r^2\theta')}{dt} = 0$. Integrating both sides with respect to t gives $r^2\theta' = c$ where c is a constant of integration.
- (c) From section 9.6, $A = \int_{\alpha}^{\beta} \frac{1}{2} r^2 d\theta$. We can replace $r^2 d\theta$ in this integral with $c dt$ from part (b). Carrying through the integration gives $A = \frac{1}{2} c_1 t + c_2$ where the c from above has been replaced by c_1 and c_2 is the constant from this integration. This result shows that A is linearly dependent on t so that equal areas are swept out in equal times.

Review Exercises

- Since $x(t) = t^2$ and $y(t) = 3t$ are defined for all real numbers, the domain of $\mathbf{r}(t)$ is all real numbers.
 - The parametric equations for the curve C are $x(t) = t^2$ and $y(t) = 3t$. We can eliminate the parameter by solving for t in $y = 3t$. We then substitute $t = \frac{y}{3}$ into x , and we get $x = \frac{y^2}{9}$. This equation represents a parabola that opens to the right with its vertex at the origin. As t increases, y increases, which gives the orientation. The curve C is shown below.

- Since

$$\mathbf{r}'(t) = \frac{d}{dt}(t^2\mathbf{i} + 3t\mathbf{j}) = \frac{d}{dt}(t^2)\mathbf{i} + \frac{d}{dt}(3t)\mathbf{j} = 2t\mathbf{i} + 3\mathbf{j},$$

$$\mathbf{r}'(2) = \boxed{4\mathbf{i} + 3\mathbf{j}}.$$

- Since the domain is restricted to $0 \leq t \leq \pi$ and $x(t) = 3 \cos t$ and $y(t) = \sin t$ are defined for all real numbers, the domain of $\mathbf{r}(t)$ is $\{t \mid 0 \leq t \leq \pi\}$.
 - The components of $\mathbf{r}(t)$ satisfy the equation $(\frac{x}{3})^2 + y^2 = \cos^2 t + \sin^2 t = 1$, so $\mathbf{r}(t)$ traces out the top half of an ellipse with its semimajor axis along the x . The curve begins at $\mathbf{r}(0) = 3\mathbf{i}$, contains the vector $\mathbf{r}(\frac{\pi}{2}) = \mathbf{j}$, and ends at $\mathbf{r}(\pi) = -3\mathbf{i}$, so the orientation is counterclockwise. The curve C is shown below.

- Since

$$\mathbf{r}'(t) = \frac{d}{dt}(3 \cos t \mathbf{i} + \sin t \mathbf{j}) = \frac{d}{dt}(3 \cos t)\mathbf{i} + \frac{d}{dt}(\sin t)\mathbf{j} = -3 \sin t \mathbf{i} + \cos t \mathbf{j},$$

$$\mathbf{r}'\left(\frac{\pi}{3}\right) = \boxed{-\frac{3\sqrt{3}}{2}\mathbf{i} + \frac{1}{2}\mathbf{j}}.$$

- Since $x(t) = t$, $y(t) = 2 \cos t$, and $z(t) = 2 \sin t$ are defined for all real numbers, the domain of $\mathbf{r}(t)$ is all real numbers.
 - The parametric equations satisfy $y^2 + z^2 = 4 \cos^2 t + 4 \sin^2 t = 4$, so any point (x, y, z) on C will lie on the right circular cylinder $y^2 + z^2 = 4$. If $t = 0$, then $\mathbf{r}(0) = 2\mathbf{j}$, so the point $(0, 2, 0)$ is on the curve. As t increases, the x -component increases, so the curve winds around the circular cylinder in the positive x direction. The curve C is shown below.

(c) Since

$$\mathbf{r}'(t) = \frac{d}{dt}(t\mathbf{i} + 2\cos t\mathbf{j} + 2\sin t\mathbf{k}) = \frac{d}{dt}t\mathbf{i} + \frac{d}{dt}(2\cos t)\mathbf{j} + \frac{d}{dt}(2\sin t)\mathbf{k} = \mathbf{i} - 2\sin t\mathbf{j} + 2\cos t\mathbf{k},$$

$$\boxed{\mathbf{r}'(0) = \mathbf{i} + 2\mathbf{k}}.$$

4. (a) Since $x(t) = t$, $y(t) = t$, and $z(t) = -2$ are defined for all real numbers, the domain of $\mathbf{r}(t)$ is all real numbers.
- (b) The components of $\mathbf{r}(t)$ are the parametric equations of a line in space containing the point $(0, 0, -2)$ in the direction of the vector $\mathbf{i} + \mathbf{j}$. As t increases, both x and y increase, which gives the orientation. The curve C is shown below.

(c) Since

$$\mathbf{r}'(t) = \frac{d}{dt}(t\mathbf{i} + t\mathbf{j} - 2\mathbf{k}) = \frac{d}{dt}t\mathbf{i} + \frac{d}{dt}t\mathbf{j} + \frac{d}{dt}(-2)\mathbf{k} = \mathbf{i} + \mathbf{j},$$

$$\mathbf{r}'(1) = \boxed{\mathbf{i} + \mathbf{j}}.$$

5.

$$\begin{aligned} \lim_{t \rightarrow 3} \left[(t-3)\mathbf{i} + \frac{t^2-3t}{t^2-9}\mathbf{j} - \frac{4}{t}\mathbf{k} \right] &= \lim_{t \rightarrow 3} (t-3)\mathbf{i} + \lim_{t \rightarrow 3} \left[\frac{t(t-3)}{(t+3)(t-3)} \right] \mathbf{j} - \lim_{t \rightarrow 3} \left(\frac{4}{t} \right) \mathbf{k} \\ &= \lim_{t \rightarrow 3} \left[\frac{t}{t+3} \right] \mathbf{j} - \frac{4}{3}\mathbf{k} = \boxed{\frac{1}{2}\mathbf{j} - \frac{4}{3}\mathbf{k}} \end{aligned}$$

6. The component function $x(t) = \frac{t}{t-2}$ is continuous for $t \neq 2$ and the component function $y(t) = \sin t$ is continuous for all real numbers. The vector function $\mathbf{r}(t)$ is not continuous at each number in the interval $(0, 2\pi)$. It has a discontinuity at $t = 2$.
7. The component function $x(t) = \frac{t}{t+1}$ is continuous for $t \neq -1$, which is not in the interval $[1, 3]$, the component function $y(t) = \sqrt{t-1}$ is continuous for all real numbers in $[1, 3]$, and the component function $z(t) = 3t$ is continuous for all real numbers, so $\mathbf{r}(t)$ is continuous.
8. Given $\mathbf{r}(t) = 3t\mathbf{i} - \ln t\mathbf{j} + 2e^t\mathbf{k}$,

$$\begin{aligned}\mathbf{r}'(t) &= \frac{d}{dt}(3t\mathbf{i} - \ln t\mathbf{j} + 2e^t\mathbf{k}) = \frac{d}{dt}(3t)\mathbf{i} - \frac{d}{dt}(\ln t)\mathbf{j} + \frac{d}{dt}(2e^t)\mathbf{k} = \boxed{3\mathbf{i} - \frac{1}{t}\mathbf{j} + 2e^t\mathbf{k}} \\ \mathbf{r}''(t) &= \frac{d}{dt}\left(3\mathbf{i} - \frac{1}{t}\mathbf{j} + 2e^t\mathbf{k}\right) = \frac{d}{dt}3\mathbf{i} - \frac{d}{dt}\left(\frac{1}{t}\right)\mathbf{j} + \frac{d}{dt}(2e^t)\mathbf{k} = \boxed{\frac{1}{t^2}\mathbf{j} + 2e^t\mathbf{k}}.\end{aligned}$$

9. Given $\mathbf{r}(t) = 2\cos t\mathbf{i} + 3\cos t\mathbf{j} + t\mathbf{k}$,

$$\begin{aligned}\mathbf{r}'(t) &= \frac{d}{dt}(2\cos t\mathbf{i} + 3\cos t\mathbf{j} + t\mathbf{k}) = \frac{d}{dt}(2\cos t)\mathbf{i} + \frac{d}{dt}(3\cos t)\mathbf{j} + \frac{d}{dt}t\mathbf{k} = \boxed{-2\sin t\mathbf{i} - 3\sin t\mathbf{j} + \mathbf{k}} \\ \mathbf{r}''(t) &= \frac{d}{dt}(-2\sin t\mathbf{i} - 3\sin t\mathbf{j} + \mathbf{k}) = \frac{d}{dt}(-2\sin t)\mathbf{i} - \frac{d}{dt}(3\sin t)\mathbf{j} + \frac{d}{dt}\mathbf{k} = \boxed{-2\cos t\mathbf{i} - 3\cos t\mathbf{j}}.\end{aligned}$$

10. The derivatives of $\mathbf{f}(t) = t\mathbf{i} - \frac{t}{2}\mathbf{j} + \mathbf{k}$ and $\mathbf{g}(t) = \sqrt{1-t}\mathbf{i} + t^3\mathbf{j} + 2(t+1)\mathbf{k}$ are $\mathbf{f}'(t) = \mathbf{i} - \frac{1}{2}\mathbf{j}$ and $\mathbf{g}'(t) = -\frac{1}{2\sqrt{1-t}}\mathbf{i} + 3t^2\mathbf{j} + 2\mathbf{k}$. To find $\frac{d}{dt}[\mathbf{f}(t) \cdot \mathbf{g}(t)]$, we use the dot product formula.

$$\begin{aligned}[\mathbf{f}(t) \cdot \mathbf{g}(t)]' &= \mathbf{f}'(t) \cdot \mathbf{g}(t) + \mathbf{f}(t) \cdot \mathbf{g}'(t) \\ &= \left[\mathbf{i} - \frac{1}{2}\mathbf{j}\right] \cdot [\sqrt{1-t}\mathbf{i} + t^3\mathbf{j} + 2(t+1)\mathbf{k}] + \left[t\mathbf{i} - \frac{t}{2}\mathbf{j} + \mathbf{k}\right] \cdot \left[-\frac{1}{2\sqrt{1-t}}\mathbf{i} + 3t^2\mathbf{j} + 2\mathbf{k}\right] \\ &= \sqrt{1-t} - \frac{1}{2}t^3 - \frac{t}{2\sqrt{1-t}} - \frac{3}{2}t^3 + 2 \\ &= \boxed{\sqrt{1-t} - 2t^3 - \frac{t}{2\sqrt{1-t}} + 2}\end{aligned}$$

To find $\frac{d}{dt}[\mathbf{f}(t) \times \mathbf{g}(t)]$, we use the cross product formula.

$$\begin{aligned}[\mathbf{f}(t) \times \mathbf{g}(t)]' &= \mathbf{f}'(t) \times \mathbf{g}(t) + \mathbf{f}(t) \times \mathbf{g}'(t) \\ &= \left[\mathbf{i} - \frac{1}{2}\mathbf{j}\right] \times [\sqrt{1-t}\mathbf{i} + t^3\mathbf{j} + 2(t+1)\mathbf{k}] + \left[t\mathbf{i} - \frac{t}{2}\mathbf{j} + \mathbf{k}\right] \times \left[-\frac{1}{2\sqrt{1-t}}\mathbf{i} + 3t^2\mathbf{j} + 2\mathbf{k}\right] \\ &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -\frac{1}{2} & 0 \\ \sqrt{1-t} & t^3 & 2(t+1) \end{vmatrix} + \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & -\frac{t}{2} & 1 \\ -\frac{1}{2\sqrt{1-t}} & 3t^2 & 2 \end{vmatrix}\end{aligned}$$

Since

$$\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -\frac{1}{2} & 0 \\ \sqrt{1-t} & t^3 & 2(t+1) \end{vmatrix} = (-t-1)\mathbf{i} - 2(t+1)\mathbf{j} + \left(t^3 + \frac{1}{2}\sqrt{1-t}\right)\mathbf{k}$$

and

$$\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & -\frac{t}{2} & 1 \\ -\frac{1}{2\sqrt{1-t}} & 3t^2 & 2 \end{vmatrix} = (-t-3t^2)\mathbf{i} - \left(2t + \frac{1}{2\sqrt{1-t}}\right)\mathbf{j} + \left(3t^3 - \frac{t}{4\sqrt{1-t}}\right)\mathbf{k},$$

$$[\mathbf{f}(t) \times \mathbf{g}(t)]' = \boxed{-(3t^2 + 2t + 1)\mathbf{i} - \left(4t + \frac{1}{2\sqrt{1-t}} + 2\right)\mathbf{j} + \left(4t^3 + \frac{1}{2}\sqrt{1-t} - \frac{t}{4\sqrt{1-t}}\right)\mathbf{k}}.$$

11. The derivatives of $\mathbf{f}(t) = t\mathbf{i} + \cos(2t)\mathbf{j} - 5\mathbf{k}$ and $\mathbf{g}(t) = 2t\mathbf{i} + \cos t\mathbf{j} + \sin t\mathbf{k}$ are $\mathbf{f}'(t) = \mathbf{i} - 2\sin(2t)\mathbf{j}$ and $\mathbf{g}'(t) = 2\mathbf{i} - \sin t\mathbf{j} + \cos t\mathbf{k}$. To find $\frac{d}{dt}[\mathbf{u}(t) \cdot \mathbf{v}(t)]$, we use the dot product formula.

$$\begin{aligned} [\mathbf{f}(t) \cdot \mathbf{g}(t)]' &= \mathbf{f}'(t) \cdot \mathbf{g}(t) + \mathbf{f}(t) \cdot \mathbf{g}'(t) \\ &= [\mathbf{i} - 2\sin(2t)\mathbf{j}] \cdot [2t\mathbf{i} + \cos t\mathbf{j} + \sin t\mathbf{k}] + [t\mathbf{i} + \cos(2t)\mathbf{j} - 5\mathbf{k}] \cdot [2\mathbf{i} - \sin t\mathbf{j} + \cos t\mathbf{k}] \\ &= 2t - 2\sin(2t)\cos t + 2t - \sin t\cos(2t) - 5\cos t \\ &= \boxed{4t - 2\sin(2t)\cos t - \sin t\cos(2t) - 5\cos t} \end{aligned}$$

To find $\frac{d}{dt}[\mathbf{f}(t) \times \mathbf{g}(t)]$, we use the cross product formula.

$$\begin{aligned} [\mathbf{f}(t) \times \mathbf{g}(t)]' &= \mathbf{f}'(t) \times \mathbf{g}(t) + \mathbf{f}(t) \times \mathbf{g}'(t) \\ &= [\mathbf{i} - 2\sin(2t)\mathbf{j}] \times [2t\mathbf{i} + \cos t\mathbf{j} + \sin t\mathbf{k}] + [t\mathbf{i} + \cos(2t)\mathbf{j} - 5\mathbf{k}] \times [2\mathbf{i} - \sin t\mathbf{j} + \cos t\mathbf{k}] \\ &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -2\sin(2t) & 0 \\ 2t & \cos t & \sin t \end{vmatrix} + \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & \cos(2t) & -5 \\ 2 & -\sin t & \cos t \end{vmatrix} \end{aligned}$$

Since

$$\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -2\sin(2t) & 0 \\ 2t & \cos t & \sin t \end{vmatrix} = -2\sin t\sin(2t)\mathbf{i} - \sin t\mathbf{j} + [\cos t + 4t\sin(2t)]\mathbf{k}$$

and

$$\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & \cos(2t) & -5 \\ 2 & -\sin t & \cos t \end{vmatrix} = [\cos t\cos(2t) - 5\sin t]\mathbf{i} - [t\cos t + 10]\mathbf{j} - [t\sin t + 2\cos(2t)]\mathbf{k},$$

$$[\mathbf{f}(t) \times \mathbf{g}(t)]' =$$

$$\boxed{(-2\sin(2t)\sin t + \cos(2t)\cos t - 5\sin t)\mathbf{i} + (-10 - \sin t - t\cos t)\mathbf{j} + (\cos t - t\sin t + 4t\sin(2t) - 2\cos(2t))\mathbf{k}}.$$

12. We are given $\mathbf{r}(t) = e^t\mathbf{i} + e^{-t}\mathbf{j} + \mathbf{k}$.

(a) $\mathbf{r}'(t) = e^t\mathbf{i} - e^{-t}\mathbf{j}$ so $\mathbf{r}'(0) = \boxed{\mathbf{i} - \mathbf{j}}$ is tangent to C at $t = 0$.

(b) $\|\mathbf{r}'(t)\| = \sqrt{e^{2t} + e^{-2t}}$. Since $\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|}$,

$$\mathbf{T}(t) = \frac{e^t\mathbf{i} - e^{-t}\mathbf{j}}{\sqrt{e^{2t} + e^{-2t}}} \quad \text{and} \quad \mathbf{T}(0) = \boxed{\frac{\sqrt{2}}{2}\mathbf{i} - \frac{\sqrt{2}}{2}\mathbf{j}}.$$

- (c) Using the Quotient and Chain Rules,

$$\mathbf{T}'(t) = \frac{\sqrt{e^{2t} + e^{-2t}}(e^t\mathbf{i} + e^{-t}\mathbf{j}) - (e^t\mathbf{i} - e^{-t}\mathbf{j})\left(\frac{1}{2}\right)(e^{2t} + e^{-2t})^{-1/2}(2e^{2t} - 2e^{-2t})}{e^{2t} + e^{-2t}}.$$

We can multiply the numerator and the denominator by $\sqrt{e^{2t} + e^{-2t}}$ to simplify.

$$\begin{aligned}\mathbf{T}'(t) &= \frac{(e^{2t} + e^{-2t})(e^t \mathbf{i} + e^{-t} \mathbf{j}) - (e^t \mathbf{i} - e^{-t} \mathbf{j})(e^{2t} - e^{-2t})}{(e^{2t} + e^{-2t})^{3/2}} \\ &= \frac{e^{3t} \mathbf{i} + e^t \mathbf{j} + e^{-t} \mathbf{i} + e^{-3t} \mathbf{j} - (e^{3t} \mathbf{i} - e^{-t} \mathbf{i} - e^t \mathbf{j} + e^{-3t} \mathbf{j})}{(e^{2t} + e^{-2t})^{3/2}} = \frac{2e^{-t} \mathbf{i} + 2e^t \mathbf{j}}{(e^{2t} + e^{-2t})^{3/2}}\end{aligned}$$

Then

$$\|\mathbf{T}'(t)\| = \sqrt{\frac{4e^{-2t} + 4e^{2t}}{(e^{2t} + e^{-2t})^3}} = \frac{2\sqrt{e^{-2t} + e^{2t}}}{(e^{2t} + e^{-2t})^{3/2}} = \frac{2}{e^{2t} + e^{-2t}}.$$

$$\text{Since } \mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|},$$

$$\mathbf{N}(t) = \frac{\frac{2e^{-t} \mathbf{i} + 2e^t \mathbf{j}}{(e^{2t} + e^{-2t})^{3/2}}}{\frac{2}{e^{2t} + e^{-2t}}} = \frac{e^{-t} \mathbf{i} + e^t \mathbf{j}}{\sqrt{e^{-2t} + e^{2t}}} \quad \text{and} \quad \mathbf{N}(0) = \boxed{\frac{\sqrt{2}}{2} \mathbf{i} + \frac{\sqrt{2}}{2} \mathbf{j}}.$$

13. We are given $\mathbf{r}(t) = t\mathbf{i} + 2t\mathbf{j} + \sqrt{1 - 5t^2}\mathbf{k}$, $-\frac{\sqrt{5}}{5} < t < \frac{\sqrt{5}}{5}$.

(a) $\mathbf{r}'(t) = \mathbf{i} + 2\mathbf{j} - \frac{5t}{\sqrt{1-5t^2}}\mathbf{k}$ so $\mathbf{r}'(0) = \boxed{\mathbf{i} + 2\mathbf{j}}$ is tangent to C at $t = 0$.

(b) $\|\mathbf{r}'(t)\| = \sqrt{1 + 4 + \frac{25t^2}{1-5t^2}} = \sqrt{\frac{5-25t^2+25t^2}{1-5t^2}} = \sqrt{\frac{5}{1-5t^2}}$. Since $\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|}$,

$$\mathbf{T}(t) = \frac{\mathbf{i} + 2\mathbf{j} - \frac{5t}{\sqrt{1-5t^2}}\mathbf{k}}{\sqrt{\frac{5}{1-5t^2}}} = \sqrt{\frac{1-5t^2}{5}}\mathbf{i} + 2\sqrt{\frac{1-5t^2}{5}}\mathbf{j} - \sqrt{5}t\mathbf{k} \quad \text{and} \quad \mathbf{T}(0) = \boxed{\frac{\sqrt{5}}{5}\mathbf{i} + \frac{2\sqrt{5}}{5}\mathbf{j}}.$$

(c) Using the Constant Multiple and Chain Rules,

$$\mathbf{T}'(t) = \left(\frac{1}{\sqrt{5}}\right) \frac{-10t}{2\sqrt{1-5t^2}}\mathbf{i} + \left(\frac{2}{\sqrt{5}}\right) \frac{-10t}{2\sqrt{1-5t^2}}\mathbf{j} - \sqrt{5}\mathbf{k} = -t\sqrt{\frac{5}{1-5t^2}}\mathbf{i} - 2t\sqrt{\frac{5}{1-5t^2}}\mathbf{j} - \sqrt{5}\mathbf{k}.$$

Then

$$\|\mathbf{T}'(t)\| = \sqrt{\frac{5t^2}{1-5t^2} + \frac{20t^2}{1-5t^2} + 5} = \sqrt{\frac{5t^2 + 20t^2 + 5 - 25t^2}{1-5t^2}} = \sqrt{\frac{5}{1-5t^2}}.$$

$$\text{Since } \mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|},$$

$$\mathbf{N}(t) = \frac{-t\sqrt{\frac{5}{1-5t^2}}\mathbf{i} - 2t\sqrt{\frac{5}{1-5t^2}}\mathbf{j} - \sqrt{5}\mathbf{k}}{\sqrt{\frac{5}{1-5t^2}}} = -t\mathbf{i} - 2t\mathbf{j} - \sqrt{1-5t^2}\mathbf{k} \quad \text{and} \quad \mathbf{N}(0) = \boxed{-\mathbf{k}}.$$

14. We are given $\mathbf{r}(t) = e^t \sin t \mathbf{i} + e^t \cos t \mathbf{j} + e^t \mathbf{k}$.

(a) $\mathbf{r}'(t) = (e^t \cos t + e^t \sin t)\mathbf{i} + (-e^t \sin t + e^t \cos t)\mathbf{j} + e^t \mathbf{k}$ so $\mathbf{r}'(0) = \boxed{\mathbf{i} + \mathbf{j} + \mathbf{k}}$ is tangent to C at $t = 0$.

(b)

$$\begin{aligned}\|\mathbf{r}'(t)\| &= \sqrt{e^{2t} \cos^2 t + 2e^{2t} \sin t \cos t + e^{2t} \sin^2 t + e^{2t} \sin^2 t - 2e^{2t} \sin t \cos t + e^{2t} \cos^2 t + e^{2t}} \\ &= \sqrt{e^{2t}(\cos^2 t + \sin^2 t + \sin^2 t + \cos^2 t + 1)} = e^t \sqrt{3}.\end{aligned}$$

$$\text{Since } \mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|},$$

$$\mathbf{T}(t) = \frac{\sqrt{3}}{3}[(\cos t + \sin t)\mathbf{i} + (-\sin t + \cos t)\mathbf{j} + \mathbf{k}] \quad \text{and} \quad \mathbf{T}(0) = \boxed{\frac{\sqrt{3}}{3}(\mathbf{i} + \mathbf{j} + \mathbf{k})}.$$

(c) Then

$$\mathbf{T}'(t) = \frac{\sqrt{3}}{3}[(-\sin t + \cos t)\mathbf{i} + (-\cos t - \sin t)\mathbf{j}]$$

and

$$\|\mathbf{T}'(t)\| = \sqrt{\frac{1}{3}(\sin^2 t - 2\sin t \cos t + \cos^2 t + \cos^2 t + 2\sin t \cos t + \sin^2 t)} = \sqrt{\frac{2}{3}} = \frac{\sqrt{6}}{3}.$$

$$\text{Since } \mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|},$$

$$\mathbf{N}(t) = \frac{\frac{\sqrt{3}}{3}[(-\sin t + \cos t)\mathbf{i} + (-\cos t - \sin t)\mathbf{j}]}{\frac{\sqrt{6}}{3}} = \frac{\sqrt{2}}{2}[(-\sin t + \cos t)\mathbf{i} + (-\cos t - \sin t)\mathbf{j}]$$

and

$$\mathbf{N}(0) = \boxed{\frac{\sqrt{2}}{2}\mathbf{i} - \frac{\sqrt{2}}{2}\mathbf{j}}.$$

15. To find the angle θ between the tangent vector of $\mathbf{r}(t)$ and $\mathbf{j}$, we use the dot product.

$$\mathbf{r}' \cdot \mathbf{j} = \|\mathbf{r}'\| \|\mathbf{j}\| \cos \theta \quad \text{so} \quad \theta = \cos^{-1} \left(\frac{\mathbf{r}' \cdot \mathbf{j}}{\|\mathbf{r}'\| \|\mathbf{j}\|} \right) = \cos^{-1} \left(\frac{\mathbf{r}' \cdot \mathbf{j}}{\|\mathbf{r}'\|} \right)$$

Given $\mathbf{r}(t) = \sin t \mathbf{i} + 3t \mathbf{j} + \cos t \mathbf{k}$, $\mathbf{r}'(t) = \cos t \mathbf{i} + 3 \mathbf{j} - \sin t \mathbf{k}$ and

$$\mathbf{r}' \cdot \mathbf{j} = 3 \quad \text{and} \quad \|\mathbf{r}'\| = \sqrt{\cos^2 t + 9 + \sin^2 t} = \sqrt{10} \quad \text{so} \quad \theta = \boxed{\cos^{-1} \left(\frac{3\sqrt{10}}{10} \right)}.$$

16. A plot of $\mathbf{r}(t) = \cos^3 t \mathbf{i} + \sin^3 t \mathbf{j}$ reveals that the curve C is not smooth on $[0, 2\pi]$. We find the arc length of the curve on $[0, \frac{\pi}{2}]$ and use symmetry to find the total arc length.

$$\mathbf{r}'(t) = -3\cos^2 t \sin t \mathbf{i} + 3\sin^2 t \cos t \mathbf{j}$$

$$\|\mathbf{r}'(t)\| = \sqrt{9\cos^4 t \sin^2 t + 9\sin^4 t \cos^2 t} = \sqrt{9\sin^2 t \cos^2 t (\cos^2 t + \sin^2 t)} = |3\sin t \cos t|.$$

Now we use the formula for arc length. Since $3\sin t \cos t$ is positive on $[0, \frac{\pi}{2}]$, $|3\sin t \cos t| = 3\sin t \cos t$. We use symmetry since $\mathbf{r}(t)$ is smooth on $[0, \frac{\pi}{2}]$.

$$s = \int_a^b \|\mathbf{r}'(t)\| dt = 4 \int_0^{\pi/2} 3\sin t \cos t dt$$

Let $\sin t = u$. Then $\cos t \, dt = du$. Now we change the limits of integration. When $t = 0$, $u = 0$, and when $t = \frac{\pi}{2}$, $u = 1$, and

$$4 \int_0^{\pi/2} 3 \sin t \cos t \, dt = 4 \int_0^1 3u \, du = 4 \left[\left(\frac{3}{2} \right) u^2 \right]_0^1 = \boxed{6}.$$

17. We are given $\mathbf{r}(t) = t\mathbf{i} + 2t\mathbf{j} + \sqrt{1 - 5t^2}\mathbf{k}$.

$$\mathbf{r}'(t) = \mathbf{i} + 2\mathbf{j} - \frac{5t}{\sqrt{1 - 5t^2}}\mathbf{k}$$

so

$$\|\mathbf{r}'(t)\| = \sqrt{1 + 4 + \frac{25t^2}{1 - 5t^2}} = \sqrt{\frac{5 - 25t^2 + 25t^2}{1 - 5t^2}} = \sqrt{\frac{5}{1 - 5t^2}}.$$

Now we use the formula for arc length.

$$s = \int_a^b \|\mathbf{r}'(t)\| \, dt = \int_0^{1/4} \sqrt{\frac{5}{1 - 5t^2}} \, dt$$

Let $u = \sqrt{5}t$. Then $du = \sqrt{5} \, dt$. Now we change the limits of integration. When $t = 0$, $u = 0$, and when $t = \frac{1}{4}$, $u = \frac{\sqrt{5}}{4}$.

$$\int_0^{1/4} \sqrt{\frac{5}{1 - 5t^2}} \, dt = \int_0^{\sqrt{5}/4} \frac{1}{\sqrt{1 - u^2}} \, du$$

We use the Table of Integrals in the subsection *Essential Integrals*.

$$\int_0^{\sqrt{5}/4} \frac{1}{\sqrt{1 - u^2}} \, du = [\sin^{-1} u]_0^{\sqrt{5}/4} = \boxed{\sin^{-1} \left(\frac{\sqrt{5}}{4} \right)}$$

18. We are given $\mathbf{r}(t) = \cos t\mathbf{i} + \sin t\mathbf{j} + \frac{t}{5}\mathbf{k}$.

$$\mathbf{r}'(t) = -\sin t\mathbf{i} + \cos t\mathbf{j} + \frac{1}{5}\mathbf{k}$$

so

$$\|\mathbf{r}'(t)\| = \sqrt{\sin^2 t + \cos^2 t + \frac{1}{25}} = \sqrt{\frac{25 + 1}{25}} = \frac{\sqrt{26}}{5}.$$

Now we use the formula for arc length.

$$s = \int_a^b \|\mathbf{r}'(t)\| \, dt = \int_0^{2\pi} \frac{\sqrt{26}}{5} \, dt = \left[\frac{t\sqrt{26}}{5} \right]_0^{2\pi} = \boxed{\frac{2\pi\sqrt{26}}{5}}$$

19. We begin by finding $\mathbf{r}'(t)$ and $\|\mathbf{r}'(t)\|$.

$$\mathbf{r}'(t) = 3\mathbf{i} + 4\mathbf{j} + 5\mathbf{k} \quad \text{and} \quad \|\mathbf{r}'(t)\| = \sqrt{9 + 16 + 25} = \sqrt{50} = 5\sqrt{2} \quad \text{for all } t.$$

Since $\|\mathbf{r}'(t)\| \neq 1$ for all t , no, the parameter t does not measure arc length along C .

20. We begin by finding $\mathbf{r}'(t)$ and $\|\mathbf{r}'(t)\|$.

$$\mathbf{r}'(t) = -3\sin t\mathbf{i} + 3\cos t\mathbf{j} + 8\mathbf{k} \quad \text{and} \quad \|\mathbf{r}'(t)\| = \sqrt{9\sin^2 t + 9\cos^2 t + 64} = \sqrt{73} \quad \text{for all } t.$$

Since $\|\mathbf{r}'(t)\| \neq 1$ for all t , no, the parameter t does not measure arc length along C .

21. To find the curvature, we need $\mathbf{r}'(t)$, $\|\mathbf{r}'(t)\|$, $\mathbf{T}(t)$, $\mathbf{T}'(t)$, and $\|\mathbf{T}'(t)\|$.

$$\begin{aligned}\mathbf{r}'(t) &= -4 \sin t \mathbf{i} - 4 \cos t \mathbf{j} \\ \|\mathbf{r}'(t)\| &= \sqrt{16 \sin^2 t + 16 \cos^2 t} = \sqrt{16} = 4 \\ \mathbf{T}(t) &= \frac{-4 \sin t \mathbf{i} - 4 \cos t \mathbf{j}}{4} = -\sin t \mathbf{i} - \cos t \mathbf{j} \\ \mathbf{T}'(t) &= -\cos t \mathbf{i} + \sin t \mathbf{j} \quad \|\mathbf{T}'(t)\| = \sqrt{\cos^2 t + \sin^2 t} = 1\end{aligned}$$

Then

$$\kappa = \frac{\|\mathbf{T}'(t)\|}{\|\mathbf{r}'(t)\|} = \boxed{\frac{1}{4}}.$$

22. To find the curvature κ , so we first find $\mathbf{r}'(t)$, $\|\mathbf{r}'(t)\|$, $\mathbf{r}''(t)$, $\mathbf{r}'(t) \times \mathbf{r}''(t)$, and $\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|$.

$$\begin{aligned}\mathbf{r}'(t) &= \mathbf{i} - \sin t \mathbf{j} + \cos t \mathbf{k} \quad \|\mathbf{r}'(t)\| = \sqrt{1 + \sin^2 t + \cos^2 t} = \sqrt{2} \\ \mathbf{r}''(t) &= -\cos t \mathbf{j} - \sin t \mathbf{k} \\ \mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -\sin t & \cos t \\ 0 & -\cos t & -\sin t \end{vmatrix} = (\sin^2 t + \cos^2 t) \mathbf{i} + \sin t \mathbf{j} - \cos t \mathbf{k} \\ &= \mathbf{i} + \sin t \mathbf{j} - \cos t \mathbf{k} \\ \|\mathbf{r}'(t) \times \mathbf{r}''(t)\| &= \sqrt{1 + \sin^2 t + \cos^2 t} = \sqrt{2}\end{aligned}$$

The curvature is

$$\kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\sqrt{2}}{(\sqrt{2})^3} = \boxed{\frac{1}{2}}.$$

23. To find the curvature, we need $\mathbf{r}'(t)$, $\|\mathbf{r}'(t)\|$, $\mathbf{T}(t)$, $\mathbf{T}'(t)$, and $\|\mathbf{T}'(t)\|$.

$$\begin{aligned}\mathbf{r}'(t) &= e^t \mathbf{i} + 4 \mathbf{j} - 5e^{-t} \mathbf{k} \quad \|\mathbf{r}'(t)\| = \sqrt{e^{2t} + 16 + 25e^{-2t}} \\ \mathbf{T}(t) &= \frac{e^t \mathbf{i} + 4 \mathbf{j} - 5e^{-t} \mathbf{k}}{\sqrt{e^{2t} + 16 + 25e^{-2t}}}\end{aligned}$$

We differentiate each component separately.

$$\begin{aligned}\frac{d}{dt} \left[\frac{e^t}{\sqrt{e^{2t} + 16 + 25e^{-2t}}} \right] &= \frac{e^t \sqrt{e^{2t} + 16 + 25e^{-2t}} - e^t \left(\frac{1}{2} \right) (e^{2t} + 16 + 25e^{-2t})^{-1/2} (2e^{2t} - 50e^{-2t})}{e^{2t} + 16 + 25e^{-2t}} \\ &= \frac{e^t (e^{2t} + 16 + 25e^{-2t}) - e^t (e^{2t} - 25e^{-2t})}{(e^{2t} + 16 + 25e^{-2t})^{3/2}} = \frac{16e^t + 50e^{-t}}{(e^{2t} + 16 + 25e^{-2t})^{3/2}} \\ \frac{d}{dt} \left[\frac{4}{\sqrt{e^{2t} + 16 + 25e^{-2t}}} \right] &= -2(e^{2t} + 16 + 25e^{-2t})^{-3/2} (2e^{2t} - 50e^{-2t}) = -\frac{4e^{2t} - 100e^{-2t}}{(e^{2t} + 16 + 25e^{-2t})^{3/2}} \\ \frac{d}{dt} \left[\frac{-5e^{-t}}{\sqrt{e^{2t} + 16 + 25e^{-2t}}} \right] &= \frac{5e^{-t} \sqrt{e^{2t} + 16 + 25e^{-2t}} + 5e^{-t} \left(\frac{1}{2} \right) (e^{2t} + 16 + 25e^{-2t})^{-1/2} (2e^{2t} - 50e^{-2t})}{e^{2t} + 16 + 25e^{-2t}} \\ &= \frac{5e^{-t} (e^{2t} + 16 + 25e^{-2t}) + 5e^{-t} (e^{2t} - 25e^{-2t})}{(e^{2t} + 16 + 25e^{-2t})^{3/2}} = \frac{10e^t + 80e^{-t}}{(e^{2t} + 16 + 25e^{-2t})^{3/2}}\end{aligned}$$

$$\begin{aligned}
\mathbf{T}'(t) &= \frac{(16e^t + 50e^{-t})\mathbf{i} - (4e^{2t} - 100e^{-2t})\mathbf{j} + (10e^t + 80e^{-t})\mathbf{k}}{(e^{2t} + 16 + 25e^{-2t})^{3/2}} \\
\|\mathbf{T}'(t)\| &= \sqrt{\frac{(16e^t + 50e^{-t})^2 + (4e^{2t} - 100e^{-2t})^2 + (10e^t + 80e^{-t})^2}{(e^{2t} + 16 + 25e^{-2t})^3}} \\
&= \sqrt{\frac{256e^{2t} + 1600 + 2500e^{-2t} + 16e^{4t} - 800 + 10000e^{-4t} + 100e^{2t} + 1600 + 6400e^{-2t}}{(e^{2t} + 16 + 25e^{-2t})^3}} \\
&= \sqrt{\frac{16e^{4t} + 356e^{2t} + 2400 + 8900e^{-2t} + 10000e^{-4t}}{(e^{2t} + 16 + 25e^{-2t})^3}} \\
&= 2\sqrt{\frac{4e^{4t} + 89e^{2t} + 600 + 2225e^{-2t} + 2500e^{-4t}}{(e^{2t} + 16 + 25e^{-2t})^3}}
\end{aligned}$$

Then

$$\kappa = \frac{\|\mathbf{T}'(t)\|}{\|\mathbf{r}'(t)\|} = \frac{2\sqrt{\frac{4e^{4t} + 89e^{2t} + 600 + 2225e^{-2t} + 2500e^{-4t}}{(e^{2t} + 16 + 25e^{-2t})^3}}}{\sqrt{e^{2t} + 16 + 25e^{-2t}}} = \boxed{\frac{2\sqrt{4e^{4t} + 89e^{2t} + 600 + 2225e^{-2t} + 2500e^{-4t}}}{(e^{2t} + 16 + 25e^{-2t})^2}}.$$

The curvature is

$$\kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \boxed{\frac{2\sqrt{100e^{-2t} + 25 + 4e^{2t}}}{(e^{2t} + 16 + 25e^{-2t})^{3/2}}}.$$

24. To find the curvature of $f(x)$ at $(1, -3)$, we need to find $f'(x)$, $f'(1)$, $f''(x)$, $f''(1)$, and $|f''(1)|$.

$$\begin{aligned}
f'(x) &= 3x^2 & f'(1) &= 3 \\
f''(x) &= 6x & f''(1) &= 6 & |f''(1)| &= 6 \\
\kappa &= \frac{|f''(1)|}{(1 + [f'(1)]^2)^{3/2}} = \frac{6}{(1 + [3]^2)^{3/2}} = \frac{6}{(10)^{3/2}} = \boxed{\frac{3\sqrt{10}}{50}}.
\end{aligned}$$

25. To find the curvature of $f(x)$ at $(0, 4)$, we need to find $f'(x)$, $f'(0)$, $f''(x)$, $f''(0)$, and $|f''(0)|$.

$$\begin{aligned}
f'(x) &= -8e^{-2x} & f'(0) &= -8 \\
f''(x) &= 16e^{-2x} & f''(0) &= 16 & |f''(0)| &= 16 \\
\kappa &= \frac{|f''(0)|}{(1 + [f'(0)]^2)^{3/2}} = \frac{16}{(1 + [-8]^2)^{3/2}} = \boxed{\frac{16}{65^{3/2}}}.
\end{aligned}$$

26. To find the radius of the osculating circle, we need to find the curvature κ , so we first find $\mathbf{r}'(t)$, $\|\mathbf{r}'(t)\|$, $\mathbf{r}''(t)$, $\mathbf{r}'(t) \times \mathbf{r}''(t)$, and $\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|$.

$$\begin{aligned}
\mathbf{r}'(t) &= -2t\mathbf{i} - e^{-t}\mathbf{j} & \|\mathbf{r}'(t)\| &= \sqrt{4t^2 + e^{-2t}} \\
\mathbf{r}''(t) &= -2\mathbf{i} + e^{-t}\mathbf{j}
\end{aligned}$$

Then

$$\begin{aligned}
\mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2t & -e^{-t} & 0 \\ -2 & e^{-t} & 0 \end{vmatrix} = (-2te^{-t} - 2e^{-t})\mathbf{k} = -2e^{-t}(t+1)\mathbf{k} \\
\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| &= |2e^{-t}(t+1)|
\end{aligned}$$

The curvature

$$\kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{|2e^{-t}(t+1)|}{(4t^2 + e^{-2t})^{3/2}}$$

and the radius of the osculating circle

$$\rho = \frac{1}{\kappa} = \frac{(4t^2 + e^{-2t})^{3/2}}{|2e^{-t}(t+1)|},$$

so the radius at $t = 0$ is $\rho = \boxed{\frac{1}{2}}$.

27. Since $x = \cos^2 t$ and $y = \sin^2 t$, we can eliminate the parameter using $x + y = \cos^2 t + \sin^2 t = 1$, so $y = 1 - x$, $-1 \leq x \leq 1$. This equation represents a line segment, so the curvature is $\kappa = 0$, and the radius of the osculating circle is

$$\rho = \frac{1}{\kappa} = \boxed{\infty}.$$

28. To find the radius of the osculating circle, we need to find the curvature κ , so we first find $\mathbf{r}'(t)$, $\|\mathbf{r}'(t)\|$, $\mathbf{r}''(t)$, $\mathbf{r}'(t) \times \mathbf{r}''(t)$, and $\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|$ for $-1 < t < 1$.

$$\begin{aligned}\mathbf{r}'(t) &= \mathbf{i} + 2\mathbf{j} - \frac{t}{\sqrt{1-t^2}}\mathbf{k} \\ \|\mathbf{r}'(t)\| &= \sqrt{1 + 4 + \frac{t^2}{1-t^2}} = \sqrt{\frac{5-5t^2+t^2}{1-t^2}} = \sqrt{\frac{5-4t^2}{1-t^2}} \\ \mathbf{r}''(t) &= \frac{-\sqrt{1-t^2} + t(\frac{1}{2})(1-t^2)^{-1/2}(-2t)}{(1-t^2)}\mathbf{k}\end{aligned}$$

We can multiply the numerator and the denominator by $\sqrt{1-t^2}$ to simplify.

$$\mathbf{r}''(t) = \frac{-1 + t^2 - t^2}{(1-t^2)^{3/2}} = -\frac{1}{(1-t^2)^{3/2}}\mathbf{k}$$

Then

$$\begin{aligned}\mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & -\frac{t}{\sqrt{1-t^2}} \\ 0 & 0 & -\frac{1}{(1-t^2)^{3/2}} \end{vmatrix} = -\frac{2}{(1-t^2)^{3/2}}\mathbf{i} + \frac{1}{(1-t^2)^{3/2}}\mathbf{j} \\ \|\mathbf{r}'(t) \times \mathbf{r}''(t)\| &= \sqrt{\frac{4}{(1-t^2)^3} + \frac{1}{(1-t^2)^3}} = \sqrt{\frac{5}{(1-t^2)^3}} = \frac{\sqrt{5}}{(1-t^2)^{3/2}}\end{aligned}$$

The curvature is

$$\kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\frac{\sqrt{5}}{(1-t^2)^{3/2}}}{\left(\frac{5-4t^2}{1-t^2}\right)^{3/2}} = \frac{\sqrt{5}}{(5-4t^2)^{3/2}}$$

and the radius of the osculating circle is

$$\rho = \frac{1}{\kappa} = \frac{(5-4t^2)^{3/2}}{\sqrt{5}},$$

so the radius at $t = 0$ is $\rho = \frac{5^{3/2}}{\sqrt{5}} = \boxed{5}$.

29. To find the curvature of $y = \sqrt[3]{x}$, $x > 0$, we need y' , y'' , and $|y''|$.

$$y' = \frac{1}{3}x^{-2/3} = \frac{1}{3x^{2/3}} \quad y'' = -\frac{2}{9}x^{-5/3} = -\frac{2}{9x^{5/3}} \quad |y''| = \frac{2}{9x^{5/3}}$$

We know that $\frac{2}{9x^{5/3}}$ is positive since $x > 0$. The curvature is

$$\kappa = \frac{|f''(x)|}{(1 + [f'(x)]^2)^{3/2}} = \frac{\frac{2}{9x^{5/3}}}{(1 + [\frac{1}{3x^{2/3}}]^2)^{3/2}} = \frac{\frac{2}{9x^{5/3}}}{\left(\frac{9x^{4/3}+1}{9x^{4/3}}\right)^{3/2}} = \boxed{\frac{6x^{1/3}}{(9x^{4/3} + 1)^{3/2}}}.$$

30. To find the curvature κ , so we first find $\mathbf{r}'(t)$, $\|\mathbf{r}'(t)\|$, $\mathbf{r}''(t)$, $\mathbf{r}'(t) \times \mathbf{r}''(t)$, and $\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|$.

$$\begin{aligned} \mathbf{r}'(t) &= -3 \sin t \cos^2 t \mathbf{i} + 3 \sin^2 t \cos t \mathbf{j} = 3 \sin t \cos t (-\cos t \mathbf{i} + \sin t \mathbf{j}) \\ \|\mathbf{r}'(t)\| &= 3 \sin t \cos t \sqrt{\cos^2 t + \sin^2 t} = 3 \sin t \cos t \\ \mathbf{r}''(t) &= (-3 \cos^3 t + 6 \sin^2 t \cos t) \mathbf{i} + (6 \sin t \cos^2 t - 3 \sin^3 t) \mathbf{j} \\ \mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3 \sin t \cos^2 t & 3 \sin^2 t \cos t & 0 \\ -3 \cos^3 t + 6 \sin^2 t \cos t & 6 \sin t \cos^2 t - 3 \sin^3 t & 0 \end{vmatrix} \\ &= 9 \sin t \cos t \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\cos t & \sin t & 0 \\ -\cos^3 t + 2 \sin^2 t \cos t & 2 \sin t \cos^2 t - \sin^3 t & 0 \end{vmatrix} \\ &= 9 \sin t \cos t (-2 \sin t \cos^3 t + \sin^3 t \cos t + \sin t \cos^3 t - 2 \sin^3 t \cos t) \mathbf{k} \\ &= 9 \sin t \cos t (-\sin t \cos^3 t - \sin^3 t \cos t) \mathbf{k} = -9 \sin^2 t \cos^2 t (\cos^2 t + \sin^2 t) \mathbf{k} \\ &= -9 \sin^2 t \cos^2 t \mathbf{k} \\ \|\mathbf{r}'(t) \times \mathbf{r}''(t)\| &= 9 \sin^2 t \cos^2 t \end{aligned}$$

The curvature is

$$\kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{9 \sin^2 t \cos^2 t}{(3 \sin t \cos t)^3} = \frac{1}{|3 \sin t \cos t|}.$$

The curvature will be minimized when the denominator is maximized. Let

$$f(t) = |3 \sin t \cos t| = \left| \frac{3}{2} \sin(2t) \right|.$$

This function is maximized when $\sin(2t) = \pm 1$, or $t = \frac{(2n+1)\pi}{4}$. Then the minimum curvature is

$$\kappa \left[\frac{(2n+1)\pi}{4} \right] = \frac{1}{\left| 3 \left(\pm \frac{1}{\sqrt{2}} \right) \left(\pm \frac{1}{\sqrt{2}} \right) \right|} = \boxed{\frac{2}{3}}.$$

31. (a) The velocity, acceleration, and speed are

$$\begin{aligned} \mathbf{v}(t) &= \mathbf{r}'(t) = \frac{d}{dt} (2 \cos t \mathbf{i} + \sin t \mathbf{j}) = \boxed{-2 \sin t \mathbf{i} + \cos t \mathbf{j}} \\ \mathbf{a}(t) &= \mathbf{r}''(t) = \frac{d}{dt} \mathbf{r}'(t) = \frac{d}{dt} (-2 \sin t \mathbf{i} + \cos t \mathbf{j}) = \boxed{-2 \cos t \mathbf{i} - \sin t \mathbf{j}} \\ v(t) &= \|\mathbf{r}'(t)\| = \sqrt{4 \sin^2 t + \cos^2 t} = \sqrt{3 \sin^2 t + \sin^2 t + \cos^2 t} = \boxed{\sqrt{3 \sin^2 t + 1}}. \end{aligned}$$

(b) The tangential component of the acceleration is

$$a_{\mathbf{T}} = v'(t) = \frac{6 \sin t \cos t}{2\sqrt{3 \sin^2 t + 1}} = \boxed{\frac{3 \sin t \cos t}{\sqrt{3 \sin^2 t + 1}}}.$$

To find the normal component of the acceleration, note that

$$a_{\mathbf{N}} = [v(t)]^2 \kappa \quad \text{and} \quad \kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{[v(t)]^3} \quad \text{so} \quad a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|}.$$

Then

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 \sin t & \cos t & 0 \\ -2 \cos t & -\sin t & 0 \end{vmatrix} = (2 \sin^2 t + 2 \cos^2 t) \mathbf{k} = 2 \mathbf{k}$$

so

$$a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|} = \frac{\|2 \mathbf{k}\|}{\sqrt{3 \sin^2 t + 1}} = \boxed{\frac{2}{\sqrt{3 \sin^2 t + 1}}}.$$

32. (a) The velocity, acceleration, and speed are

$$\begin{aligned} \mathbf{v}(t) &= \mathbf{r}'(t) = \frac{d}{dt} (e^t \sin t \mathbf{i} + e^{-t} \mathbf{j}) = \boxed{(e^t \sin t + e^t \cos t) \mathbf{i} - e^{-t} \mathbf{j}} \\ \mathbf{a}(t) &= \mathbf{r}''(t) = \frac{d}{dt} \mathbf{r}'(t) = \frac{d}{dt} [(e^t \sin t + e^t \cos t) \mathbf{i} - e^{-t} \mathbf{j}] \\ &= (e^t \sin t + e^t \cos t + e^t \cos t - e^t \sin t) \mathbf{i} + e^{-t} \mathbf{j} = \boxed{2e^t \cos t \mathbf{i} + e^{-t} \mathbf{j}} \\ v(t) &= \|\mathbf{r}'(t)\| = \sqrt{e^{2t} \sin^2 t + 2e^{2t} \sin t \cos t + e^{2t} \cos^2 t + e^{-2t}} \\ &= \boxed{\sqrt{e^{2t} + 2e^{2t} \sin t \cos t + e^{-2t}}}. \end{aligned}$$

(b) The tangential component of the acceleration is

$$\begin{aligned} a_{\mathbf{T}} &= v'(t) = \frac{2e^{2t} + 4e^{2t} \sin t \cos t + 2e^{2t} \cos^2 t - 2e^{2t} \sin^2 t - 2e^{-2t}}{2\sqrt{e^{2t} + 2e^{2t} \sin t \cos t + e^{-2t}}} \\ &= \boxed{\frac{e^{2t} + 2e^{2t} \sin t \cos t + e^{2t} \cos^2 t - e^{2t} \sin^2 t - e^{-2t}}{\sqrt{e^{2t} + 2e^{2t} \sin t \cos t + e^{-2t}}}}. \end{aligned}$$

To find the normal component of the acceleration, note that

$$a_{\mathbf{N}} = [v(t)]^2 \kappa \quad \text{and} \quad \kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{[v(t)]^3} \quad \text{so} \quad a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|}.$$

Then

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ e^t \sin t + e^t \cos t & -e^{-t} & 0 \\ 2e^t \cos t & e^{-t} & 0 \end{vmatrix} = (\sin t + \cos t + 2 \cos t) \mathbf{k} = (\sin t + 3 \cos t) \mathbf{k}$$

so

$$a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|} = \frac{\|(\sin t + 3 \cos t) \mathbf{k}\|}{\sqrt{e^{2t} + 2e^{2t} \sin t \cos t + e^{-2t}}} = \boxed{\frac{|\sin t + 3 \cos t|}{\sqrt{e^{2t} + 2e^{2t} \sin t \cos t + e^{-2t}}}}.$$

33. (a) The velocity, acceleration, and speed are

$$\begin{aligned}\mathbf{v}(t) &= \mathbf{r}'(t) = \frac{d}{dt} (e^t \mathbf{i} + e^{-t} \mathbf{j} + \mathbf{k}) = \boxed{e^t \mathbf{i} - e^{-t} \mathbf{j}} \\ \mathbf{a}(t) &= \mathbf{r}''(t) = \frac{d}{dt} \mathbf{r}'(t) = \frac{d}{dt} (e^t \mathbf{i} - e^{-t} \mathbf{j}) = \boxed{e^t \mathbf{i} + e^{-t} \mathbf{j}} \\ v(t) &= \|\mathbf{r}'(t)\| = \boxed{\sqrt{e^{2t} + e^{-2t}}}.\end{aligned}$$

- (b) The tangential component of the acceleration is

$$a_{\mathbf{T}} = v'(t) = \frac{2e^{2t} - 2e^{-2t}}{2\sqrt{e^{2t} + e^{-2t}}} = \boxed{\frac{e^{2t} - e^{-2t}}{\sqrt{e^{2t} + e^{-2t}}}}.$$

To find the normal component of the acceleration, note that

$$a_{\mathbf{N}} = [v(t)]^2 \kappa \quad \text{and} \quad \kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{[v(t)]^3} \quad \text{so} \quad a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|}.$$

Then

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ e^t & -e^{-t} & 0 \\ e^t & e^{-t} & 0 \end{vmatrix} = 2\mathbf{k}$$

so

$$a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|} = \frac{\|2\mathbf{k}\|}{\sqrt{e^{2t} + e^{-2t}}} = \boxed{\frac{2}{\sqrt{e^{2t} + e^{-2t}}}}.$$

34. (a) The velocity, acceleration, and speed are

$$\begin{aligned}\mathbf{v}(t) &= \mathbf{r}'(t) = \frac{d}{dt} (e^t \sin t \mathbf{i} + e^t \cos t \mathbf{j} + e^t \mathbf{k}) = \boxed{(e^t \sin t + e^t \cos t) \mathbf{i} + (e^t \cos t - e^t \sin t) \mathbf{j} + e^t \mathbf{k}} \\ \mathbf{a}(t) &= \mathbf{r}''(t) = \frac{d}{dt} \mathbf{r}'(t) = \frac{d}{dt} [e^t \sin t + e^t \cos t] \mathbf{i} + \frac{d}{dt} [e^t \cos t - e^t \sin t] \mathbf{j} + \frac{d}{dt} e^t \mathbf{k} \\ &= (e^t \sin t + e^t \cos t + e^t \cos t - e^t \sin t) \mathbf{i} + (e^t \cos t - e^t \sin t - e^t \sin t - e^t \cos t) \mathbf{j} + e^t \mathbf{k} \\ &= \boxed{2e^t \cos t \mathbf{i} - 2e^t \sin t \mathbf{j} + e^t \mathbf{k}} \\ v(t) &= \|\mathbf{r}'(t)\| \\ &= \sqrt{e^{2t} \sin^2 t + 2e^{2t} \sin t \cos t + e^{2t} \cos^2 t + e^{2t} \cos^2 t - 2e^{2t} \sin t \cos t + e^{2t} \sin^2 t + e^{2t}} \\ &= \sqrt{e^{2t} (\sin^2 t + \cos^2 t + \cos^2 t + \sin^2 t + 1)} = \boxed{e^t \sqrt{3}}.\end{aligned}$$

- (b) The tangential component of the acceleration is

$$a_{\mathbf{T}} = v'(t) = \boxed{e^t \sqrt{3}}.$$

To find the normal component of the acceleration, note that

$$a_{\mathbf{N}} = [v(t)]^2 \kappa \quad \text{and} \quad \kappa = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{[v(t)]^3} \quad \text{so} \quad a_{\mathbf{N}} = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|}.$$

Then

$$\begin{aligned}\mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ e^t \sin t + e^t \cos t & e^t \cos t - e^t \sin t & e^t \\ 2e^t \cos t & -2e^t \sin t & e^t \end{vmatrix} \\ &= (e^{2t} \cos t + e^{2t} \sin t)\mathbf{i} - (e^{2t} \sin t - e^{2t} \cos t)\mathbf{j} + (-2e^{2t} \sin^2 t - 2e^{2t} \cos^2 t)\mathbf{k} \\ &= [e^{2t}(\cos t + \sin t)]\mathbf{i} - [e^{2t}(\sin t - \cos t)]\mathbf{j} - 2e^{2t}\mathbf{k}\end{aligned}$$

so

$$\begin{aligned}a_N &= \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{\|[e^{2t}(\cos t + \sin t)]\mathbf{i} - [e^{2t}(\sin t - \cos t)]\mathbf{j} - 2e^{2t}\mathbf{k}\|}{e^{3t}\sqrt{3}} \\ &= \frac{e^{2t}\sqrt{\cos^2 t + 2\sin t \cos t + \sin^2 t + \sin^2 t - 2\sin t \cos t + \cos^2 t + 4}}{e^{3t}\sqrt{3}} \\ &= \frac{e^{2t}\sqrt{6}}{e^{3t}\sqrt{3}} = \boxed{e^t\sqrt{2}}.\end{aligned}$$

35. The velocity and acceleration of a particle moving on the cycloid are

$$\begin{aligned}\mathbf{v}(t) = \mathbf{r}'(t) &= \boxed{(\pi - \cos(\pi t))\mathbf{i} + \pi \sin(\pi t)\mathbf{j}} \\ \mathbf{a}(t) = \mathbf{r}''(t) &= \frac{d}{dt}\mathbf{r}'(t) = \boxed{\pi^2 \sin(\pi t)\mathbf{i} + \pi^2 \cos(\pi t)\mathbf{j}}.\end{aligned}$$

36. (a) The velocity and acceleration of a particle moving on the parabola are

$$\begin{aligned}\mathbf{v}(t) = \mathbf{r}'(t) &= \boxed{(2t - 2)\mathbf{i} + \mathbf{j}} \\ \mathbf{a}(t) = \mathbf{r}''(t) &= \frac{d}{dt}\mathbf{r}'(t) = \boxed{2\mathbf{i}}.\end{aligned}$$

(b) The speed of the particle is $v(t) = \|\mathbf{r}'(t)\| = \sqrt{4t^2 - 8t + 4 + 1} = \sqrt{4t^2 - 8t + 5}$. The speed $v(t) = \sqrt{4t^2 - 8t + 5} = 0$ when $4t^2 - 8t + 5 = 0$. Using the quadratic equation,

$$t = \frac{8 \pm \sqrt{64 - 4(4)(5)}}{2(4)} = \frac{8 \pm \sqrt{-16}}{8},$$

so the speed of the particle is $\boxed{\text{never } 0}$.

37. We integrate each component individually. We use the substitution $u = t - 2$ and $du = dt$ in the second component.

$$\begin{aligned}\int (t^2 - 2)\mathbf{i} dt - \int (t - 2)^2 \mathbf{j} dt + \int e^{2t} \mathbf{k} dt &= \left(\frac{1}{3}t^3 - 2t + c_1\right)\mathbf{i} - \left[\frac{1}{3}(t - 2)^3 + c_2\right]\mathbf{j} + \left(\frac{1}{2}e^{2t} + c_3\right)\mathbf{k} \\ &= \left(\frac{1}{3}t^3 - 2t\right)\mathbf{i} - \frac{1}{3}(t - 2)^3 \mathbf{j} + \frac{1}{2}e^{2t}\mathbf{k} + c_1\mathbf{i} + c_2\mathbf{j} + c_3\mathbf{k} \\ &= \boxed{\left(\frac{1}{3}t^3 - 2t\right)\mathbf{i} - \frac{1}{3}(t - 2)^3 \mathbf{j} + \frac{1}{2}e^{2t}\mathbf{k} + \mathbf{c}}\end{aligned}$$

38. We integrate each component individually. We use the substitution $u = \frac{t}{2}$, $du = \frac{1}{2} dt$, $dt = 2 du$ in the

first component, and we use the identity $\sin^2 t = \frac{1}{2} - \frac{1}{2} \cos(2t)$ in the second component.

$$\begin{aligned}
 \int \cos\left(\frac{t}{2}\right) \mathbf{i} dt + \int \sin^2\left(\frac{t}{2}\right) \mathbf{j} dt + \int 3t \mathbf{k} dt &= \int 2 \cos u \mathbf{i} du + \frac{1}{2} \int (1 - \cos t) \mathbf{j} dt + \int 3t \mathbf{k} dt \\
 &= (2 \sin u + c_1) \mathbf{i} + \frac{1}{2} (t - \sin t + c_2) \mathbf{j} + \left(\frac{3}{2} t^2 + c_3\right) \mathbf{k} \\
 &= \left[2 \sin\left(\frac{t}{2}\right) + c_1\right] \mathbf{i} + \frac{1}{2} (t - \sin t + c_2) \mathbf{j} + \left(\frac{3}{2} t^2 + c_3\right) \mathbf{k} \\
 &= 2 \sin\left(\frac{t}{2}\right) \mathbf{i} + \frac{1}{2} (t - \sin t) \mathbf{j} + \frac{3}{2} t^2 \mathbf{k} + c_1 \mathbf{i} + c_2 \mathbf{j} + c_3 \mathbf{k} \\
 &= \boxed{2 \sin\left(\frac{t}{2}\right) \mathbf{i} + \frac{1}{2} (t - \sin t) \mathbf{j} + \frac{3}{2} t^2 \mathbf{k} + \mathbf{c}}
 \end{aligned}$$

39. To find the general solution to the differential equation, we integrate each component. We use the Table of Integrals in the subsection *Integrals Containing Exponential and Logarithmic Functions* or use integration by parts for the integral of the second component.

$$\mathbf{r}(t) = \int \mathbf{r}'(t) dt = \int (e^{2t} \mathbf{i} + \ln t \mathbf{j} + 2e^t \mathbf{k}) dt = \left(\frac{1}{2} e^{2t} + c_1\right) \mathbf{i} + (t \ln t - t + c_2) \mathbf{j} + (2e^t + c_3) \mathbf{k}$$

Now we use the initial condition $\mathbf{r}(1) = \mathbf{j} + \mathbf{k}$

$$\mathbf{r}(1) = \left(\frac{1}{2} e^2 + c_1\right) \mathbf{i} + (-1 + c_2) \mathbf{j} + (2e + c_3) \mathbf{k} = \mathbf{j} + \mathbf{k}$$

from which we find

$$c_1 = -\frac{1}{2} e^2 \quad c_2 = 2 \quad c_3 = 1 - 2e.$$

The vector function is $\mathbf{r} = \mathbf{r}(t) = \boxed{\left(\frac{1}{2} e^{2t} - \frac{1}{2} e^2\right) \mathbf{i} + (t \ln t - t + 2) \mathbf{j} + (2e^t + 1 - 2e) \mathbf{k}}.$

40. To find the general solution to the differential equation, we integrate each component. For the first component, we use the substitution $u = \sin t$, $du = \cos t dt$.

$$\mathbf{r}(t) = \int \mathbf{r}'(t) dt = \int (\sin t \cos t \mathbf{i} + \tan t \sec t \mathbf{j} + t \mathbf{k}) dt = \left(\frac{1}{2} \sin^2 t + c_1\right) \mathbf{i} + (\sec t + c_2) \mathbf{j} + \left(\frac{1}{2} t^2 + c_3\right) \mathbf{k}.$$

Now we use the initial condition $\mathbf{r}(0) = \mathbf{i} + \mathbf{k}$

$$\mathbf{r}(0) = c_1 \mathbf{i} + (1 + c_2) \mathbf{j} + c_3 \mathbf{k} = \mathbf{i} + \mathbf{k}$$

from which we find

$$c_1 = 1 \quad c_2 = -1 \quad c_3 = 1.$$

The vector function is $\mathbf{r} = \mathbf{r}(t) = \boxed{\left(\frac{1}{2} \sin^2 t + 1\right) \mathbf{i} + (\sec t - 1) \mathbf{j} + \left(\frac{1}{2} t^2 + 1\right) \mathbf{k}}.$

41. The general solution to the differential equation is

$$\mathbf{r}(t) = \int \mathbf{r}'(t) dt = \int \left(\cos t \mathbf{i} - \sin t \mathbf{j} + \frac{t}{2} \mathbf{k}\right) dt = (\sin t + c_1) \mathbf{i} + (\cos t + c_2) \mathbf{j} + \left(\frac{1}{4} t^2 + c_3\right) \mathbf{k}.$$

Now we use the initial condition $\mathbf{r}(0) = \mathbf{i}$

$$\mathbf{r}(0) = c_1\mathbf{i} + (1 + c_2)\mathbf{j} + c_3\mathbf{k} = \mathbf{i}$$

from which we find

$$c_1 = 1 \quad c_2 = -1 \quad c_3 = 0.$$

The vector function is $\mathbf{r} = \mathbf{r}(t) = \boxed{(\sin t + 1)\mathbf{i} + (\cos t - 1)\mathbf{j} + \frac{1}{4}t^2\mathbf{k}}$.

42. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int (\tan t \sec t \mathbf{i} + \cos t \mathbf{j}) dt = (\sec t + c_1)\mathbf{i} + (\sin t + c_2)\mathbf{j}.$$

Since $\mathbf{v}(0) = \mathbf{0}$, $c_1 = -1$ and $c_2 = 0$, the velocity vector is

$$\mathbf{v}(t) = \boxed{(\sec t - 1)\mathbf{i} + \sin t \mathbf{j}}$$

and the speed is

$$v(t) = \|\mathbf{v}(t)\| = \boxed{\sqrt{\sec^2 t - 2\sec t + 1 + \sin^2 t}}.$$

To find the position vector, we integrate the velocity vector. We use the Table of Integrals in the subsection *Essential Integrals* for $\int \sec t dt$. Then the position vector of the particle is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int [(\sec t - 1)\mathbf{i} + \sin t \mathbf{j}] dt = (\ln |\sec t + \tan t| - t + d_1)\mathbf{i} + (-\cos t + d_2)\mathbf{j}.$$

Since $\mathbf{r}(0) = \mathbf{0}$, $d_1 = 0$ and $d_2 = 1$, the position vector is given by

$$\mathbf{r}(t) = \boxed{(\ln |\sec t + \tan t| - t)\mathbf{i} + (1 - \cos t)\mathbf{j}}.$$

43. The information in the problem gives $v_0 = 500$ m/s, $\theta = 45^\circ$, and $\mathbf{r}(0) = 30\mathbf{j}$. Then $\mathbf{v}(0) = 500 \cos 45^\circ \mathbf{i} + 500 \sin 45^\circ \mathbf{j} = 250\sqrt{2}\mathbf{i} + 250\sqrt{2}\mathbf{j}$. Assuming the only force that acts on the projectile is gravity, $\mathbf{a}(t) = -9.8\mathbf{j}$. The velocity vector $\mathbf{v}(t)$ is

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = \int -9.8\mathbf{j} dt = c_1\mathbf{i} + (-9.8t + c_2)\mathbf{j}$$

Now we use the initial condition $\mathbf{v}(0) = 250\sqrt{2}\mathbf{i} + 250\sqrt{2}\mathbf{j}$

$$\mathbf{v}(0) = c_1\mathbf{i} + c_2\mathbf{j} = 250\sqrt{2}\mathbf{i} + 250\sqrt{2}\mathbf{j}$$

from which we find

$$c_1 = 250\sqrt{2} \quad c_2 = 250\sqrt{2}.$$

The velocity vector is

$$\mathbf{v}(t) = 250\sqrt{2}\mathbf{i} + (-9.8t + 250\sqrt{2})\mathbf{j}.$$

The position vector of the projectile is given by

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = \int [250\sqrt{2}\mathbf{i} + (-9.8t + 250\sqrt{2})\mathbf{j}] dt = (250\sqrt{2}t + d_1)\mathbf{i} + (-4.9t^2 + 250\sqrt{2}t + d_2)\mathbf{j}.$$

Since $\mathbf{r}(0) = 30\mathbf{j}$, $d_1 = 0$ and $d_2 = 30$, the position vector is given by

$$\mathbf{r}(t) = 250\sqrt{2}t\mathbf{i} + (-4.9t^2 + 250\sqrt{2}t + 30)\mathbf{j}.$$

We want to find the value of the x -component when the y -component is 0. We find the time at which that occurs. Solving $y = -4.9t^2 + 250\sqrt{2}t + 30 = 0$ gives $t \approx 72.239$ sec. Substituting this time into the x -component gives the position where the projectile strikes the ground.

$$x = 250\sqrt{2}(72.239) = \quad \text{so } x \approx 25540$$

The position where the projectile strikes the ground is approximately 25,540 m away from the point where it was launched.

44. Answers will vary, but Kepler's three Laws of Planetary Motion are

- The orbit of each planet is an ellipse with the Sun at a focus,
- A line joining the Sun to a planet sweeps out equal areas in equal times, and
- The square of the period of revolution of a planet is proportional to the cube of the length of the semimajor axis of the planets elliptical orbit.

Chapter 12: Functions of Several Variables

12.1: Functions of Two or More Variables and Their Graphs

Concepts and Vocabulary

1. Since the ordered pair $(2, 3)$ indicates that $x = 2$ and $y = 3$, $f(2, 3) = \sqrt{16 - 2^2 - 3^2} = \sqrt{16 - 4 - 9} = \boxed{\sqrt{3}}$.
2. True. More specifically, the domain of a function is the nonempty set of points in the xy -plane for which the function is defined. See the definition of “domain” (p. 810).
3. The independent variables are x, y , and z , and the dependent variable is w .
4. True. A level curve is the projection of a contour line onto the xy -plane.

Skill Building

5. (a) $f(0, 1) = 3 \cdot 0 + 2 \cdot 1 + 0 \cdot 1 = 0 + 2 + 0 = \boxed{2}$;
 (b) $f(2, 1) = 3 \cdot 2 + 2 \cdot 1 + 2 \cdot 1 = 6 + 2 + 2 = \boxed{10}$;
 (c) $f(x + \Delta x, y) = 3(x + \Delta x) + 2y + (x + \Delta x)y = \boxed{3x + 3\Delta x + 2y + xy + y\Delta x}$;
 (d) $f(x, y + \Delta y) = 3x + 2(y + \Delta y) + x(y + \Delta y) = \boxed{3x + 2y + 2\Delta y + xy + x\Delta y}$.
6. (a) $f(0, 1) = 0^2 \cdot 1 + 0 + 1 = 0 + 0 + 1 = \boxed{1}$;
 (b) $f(2, 1) = 2^2 \cdot 1 + 2 + 1 = 4 + 2 + 1 = \boxed{7}$;
 (c) $f(x + \Delta x, y) = (x + \Delta x)^2 y + (x + \Delta x) + 1 = (x^2 + 2x\Delta x + (\Delta x)^2)y + x + \Delta x + 1$
 $= \boxed{x^2 y + (2xy + 1)\Delta x + y(\Delta x)^2 + x + 1}$;
 (d) $f(x, y + \Delta y) = x^2(y + \Delta y) + x + 1 = \boxed{x^2 y + x^2 \Delta y + x + 1}$.
7. (a) $f(0, 1) = \sqrt{0 \cdot 1} + 0 = 0 + 0 = \boxed{0}$;
 (b) $f(a^2, t^2) = \sqrt{a^2 t^2} + a^2 = |at| + a^2 = \boxed{at + a^2}$ (because $a > 0$ and $t > 0$);
 (c) $f(x + \Delta x, y) = \sqrt{(x + \Delta x)y} + (x + \Delta x) = \boxed{\sqrt{xy + y\Delta x} + x + \Delta x}$;
 (d) $f(x, y + \Delta y) = \sqrt{x(y + \Delta y)} + x = \boxed{\sqrt{xy + x\Delta y} + x}$.
8. (a) $f(1, -1) = e^{1+(-1)} = e^0 = \boxed{1}$;
 (b) $f(x + \Delta x, y) = e^{(x+\Delta x)+y} = \boxed{e^{x+y+\Delta x}}$;
 (c) $f(x, y + \Delta y) = e^{x+(y+\Delta y)} = \boxed{e^{x+y+\Delta y}}$.
9. (a) $F(0, 0, 1) = \frac{3 \cdot 0 \cdot 0 + 1}{0^2 + 0^2 + 1^2} = \frac{1}{1} = \boxed{1}$;
 (b) $F(0, 1, 0) = \frac{3 \cdot 0 \cdot 1 + 0}{0^2 + 1^2 + 0^2} = \frac{0}{1} = \boxed{0}$;
 (c) $F(\sin t, \cos t, 0) = \frac{3 \sin t \cos t + 0}{\sin^2 t + \cos^2 t + 0^2} = \frac{3 \sin t \cos t}{1} = \boxed{3 \sin t \cos t}$.
10. (a) $F(1, -1, 1) = \frac{1 \cdot (-1) \cdot 1}{1^2 + (-1)^2 + 1^2} = \frac{-1}{3} = \boxed{-\frac{1}{3}}$;

$$(b) F(a, a, a) = \frac{a \cdot a \cdot a}{a^2 + a^2 + a^2} = \frac{a^3}{3a^2} = \boxed{\frac{a}{3}};$$

$$(c) F(\sin t, \cos t, a) = \frac{\sin t \cdot \cos t \cdot a}{\sin^2 t + \cos^2 t + a^2} = \boxed{\frac{a \sin t \cos t}{1 + a^2}}.$$

11. (a) $x(0) = \sqrt{0} = 0$ and $y(0) = 0^2 = 0$, so $f(x(0), y(0)) = f(0, 0) = 3 \cdot 0 \cdot 0 - 0^2 = 0 - 0 = \boxed{0}$;
 (b) $x(1) = \sqrt{1} = 1$ and $y(1) = 1^2 = 1$, so $f(x(1), y(1)) = f(1, 1) = 3 \cdot 1 \cdot 1 - 1^2 = 3 - 1 = \boxed{2}$;
 (c) $x(4) = \sqrt{4} = 2$ and $y(4) = 4^2 = 16$, so $f(x(4), y(4)) = f(2, 16) = 3 \cdot 2 \cdot 16 - 2^2 = 96 - 4 = \boxed{92}$.
12. (a) $x(0) = 0$ and $y(0) = 0^2 = 0$, so $f(x(0), y(0)) = f(0, 0) = 0^2 + 0 \cdot 0 + 0^2 = 0 + 0 + 0 = \boxed{0}$;
 (b) $x(1) = 1$ and $y(1) = 1^2 = 1$, so $f(x(1), y(1)) = f(1, 1) = 1^2 + 1 \cdot 1 + 1^2 = 1 + 1 + 1 = \boxed{3}$;
 (c) $x(2) = 2$ and $y(2) = 2^2 = 4$, so $f(x(2), y(2)) = f(2, 4) = 2^2 + 2 \cdot 4 + 4^2 = 4 + 8 + 16 = \boxed{28}$.
13. In order for $f(x, y)$ to be defined, both square roots need to evaluate only nonnegative numbers. So, we require that $x \geq 0$ and $y \geq 0$. However, the denominator $\sqrt{y}$ also cannot be zero, which means y cannot be zero, which restricts our inequality further to $y > 0$. So, the domain is the set of points (x, y) where $x \geq 0, y > 0$, or the set $\boxed{\{(x, y) | x \geq 0, y > 0\}}$.

14. In order for $f(x, y)$ to be defined, both square roots need to evaluate only nonnegative numbers. So, we require that $x \geq 0$ and $y \geq 0$. So, the domain is the set of points (x, y) where $x \geq 0, y \geq 0$, or the set $\boxed{\{(x, y) | x \geq 0, y \geq 0\}}$.

15. In order for $f(x, y)$ to be defined, the square root must evaluate only nonnegative numbers, i.e. we require that $xy \geq 0$. This inequality will be satisfied under either of the following two sets of conditions: $x, y \geq 0$, $x, y \leq 0$. So, the domain is the union of the sets $\{(x, y) | x, y \geq 0\}$ and $\{(x, y) | x, y \leq 0\}$, which can also be written as the set $\{(x, y) | x, y \geq 0 \text{ or } x, y \leq 0\}$.

16. In order for $f(x, y)$ to be defined, the denominator $x^2 + y^2$ cannot be zero. So, the domain is the set of points (x, y) where $x^2 + y^2 \neq 0$. Since $x^2 + y^2 = 0$ only when x and y are both zero, the domain is the set of all points (x, y) with the exception of the point $(0, 0)$. So the domain is the set $\{(x, y) | (x, y) \neq (0, 0)\}$.

17. Because both the functions e^x and $\sin y$ are defined for all real numbers x and y , the domain of this function is the entire xy -plane, or $\{(x, y) | x \text{ is any real number, } y \text{ is any real number}\}$.

18. In order for $f(x, y)$ to be defined, both $\ln x$ and $\ln y$ must be defined, which means that we must have $x > 0$ and $y > 0$. Furthermore, the denominator cannot be zero, which means that we must have $\ln y \neq 0$, or $y \neq 1$. Therefore, the domain must be the set $\{(x, y) | x > 0, y > 0 \text{ and } y \neq 1\}$.

19. In order for $f(x, y)$ to be defined, the expression under the radical, $\frac{x^2 + y^2}{x^2 - y^2}$ must be nonnegative. This can occur only if $x^2 + y^2 \geq 0$ and $x^2 - y^2 \geq 0$, or $x^2 + y^2 \leq 0$ and $x^2 - y^2 \leq 0$. The second case will only occur when $(x, y) = (0, 0)$, since $x^2 + y^2 > 0$ for all $(x, y) \neq (0, 0)$. But, this will also make the denominator of the argument of the square root 0, which is not allowed. So, the second case may be ruled out and we consider only the case where $x^2 + y^2 \geq 0$ and $x^2 - y^2 \geq 0$. Before we do so, we note further that in fact, because $x^2 - y^2$ appears in the denominator, we may restrict this inequality further to $x^2 - y^2 > 0$, and also, since we have already pointed out that $(0, 0)$ is not in the domain, we know that we will also have the stricter requirement that $x^2 + y^2 > 0$. This occurs for $(x, y) \neq (0, 0)$, so we only need to further consider the inequality $x^2 - y^2 > 0$. Therefore, the domain can be written as the set $\{(x, y) | x^2 - y^2 > 0\}$.

To obtain the graph, we factor to obtain $x^2 - y^2 = (x - y)(x + y) > 0$, which will occur only when $x - y, x + y > 0$ or $x - y, x + y < 0$. We may rewrite these as $x > y, x > -y$, or $x < y, x < -y$. The domain is therefore the union of the sets $\{(x, y) | x > y, x > -y\}$ and $\{(x, y) | x < y, x < -y\}$, which can be graphed as follows:

20. In order for $f(x, y)$ to be defined, the quantity under the radical must be nonnegative. However, the numerator of that quantity, $x^2 + y^2$, is always positive or zero. It is zero only when $(x, y) = (0, 0)$; however, when $(x, y) = (0, 0)$, the function is not defined because the denominator is zero. When $x^2 + y^2$ is positive, the denominator must also be positive in order for the quantity under the radical to be positive. The denominator is positive when $xy > 0$; in other words, when $x > 0$ and $y > 0$, as well as when $x < 0$ and $y < 0$. Therefore, the domain is the set $\{(x, y) | xy > 0\}$, which can also be written as the set $\{(x, y) | x > 0, y > 0 \text{ or } x < 0, y < 0\}$.

21. In order for this function to be defined, the denominator must be nonzero and the expression under the radical must be nonnegative. Combining these yields the inequality $2y + x^2 > 0$. The domain of the function is therefore the set $\{(x, y) | 2y + x^2 > 0\}$. To obtain the graph, we note that the inequality is equivalent to $y > -\frac{x^2}{2}$, which can be graphed as follows:

22. In order for this function to be defined, the quantity $x^2 - y^2$, which we need to take the logarithm of, must be positive. So (x, y) is in the domain when $x^2 - y^2 > 0$. Factoring, we obtain $x^2 - y^2 = (x - y)(x + y) > 0$, which will occur only when $x - y, x + y > 0$ or $x - y, x + y < 0$. We may rewrite these as $x > y, x > -y$, or $x < y, x < -y$. The domain is therefore the union of the sets $\{(x, y) | x > y, x > -y\}$ and $\{(x, y) | x < y, x < -y\}$, which can also be written as the set $\{(x, y) | x > y, x > -y \text{ or } x < y, x < -y\}$.

23. In order for this function to be defined, the denominator must be nonzero and the expression under the radical must be nonnegative. Combining these yields the inequality $9 - x^2 - y^2 > 0$. We may rewrite this as $x^2 + y^2 < 9$, which we recognize as the interior of the circle of radius 3 centered at the origin. The domain is therefore the set $\{(x, y) | x^2 + y^2 < 9\}$.

24. Since the inverse tangent function is defined for all real numbers, the domain of this function is the entire xy -plane, or $\{(x, y) | x \text{ is any real number, } y \text{ is any real number}\}$.

25. Because of the z^2 in the denominator, the function will be defined everywhere, except when $z^2 = 0$, which is equivalent to $z = 0$. So the domain is $\{(x, y, z) | z \neq 0\}$.
26. While e^z is always defined, $\ln(x^2 + y^2)$ is defined only when $x^2 + y^2 > 0$; however, this is always true, except when x and y are both equal to zero. So the domain is $\{(x, y, z) | (x, y) \neq (0, 0)\}$, which can also be written as $\{(x, y, z) | x \neq 0 \text{ and } y \neq 0\}$.
27. Because of the $\cos y$ in the denominator, the function is defined only when $\cos y \neq 0$. We know that $\cos y = 0$ when $y = \frac{(2k+1)\pi}{2}$ for k an integer, so the domain is $\{(x, y, z) | y \neq \frac{(2k+1)\pi}{2} \text{ for } k \text{ an integer}\}$.
28. Because of the $\sqrt{x^2 + y^2 + z^2}$ in the denominator, the function is defined only when $x^2 + y^2 + z^2 > 0$. However, this is always true, except when $(x, y, z) = (0, 0, 0)$. So the domain is $\{(x, y, z) | (x, y, z) \neq (0, 0, 0)\}$.
29. By rewriting the equation as $z = 3 - x - y$, we see that this is a plane with z -intercept 3. We can also find the x - and y -intercepts by setting y, z and x, z equal to 0 respectively. This yields intercepts of $(3, 0, 0)$ and $(0, 3, 0)$. Also, by rearranging the equation into $x + y + z = 3$, we can see that a normal vector for this plane is $\langle 1, 1, 1 \rangle$.

30. By rewriting the equation as $z = 2 + x - y$, we see that this is a plane with z -intercept 2. We can also find the x - and y -intercepts by setting y, z and x, z equal to 0 respectively. This yields intercepts of $(-2, 0, 0)$ and $(0, 2, 0)$. Also, by rearranging the equation into $-x + y + z = 2$, we can see that a normal vector for this plane is $\langle -1, 1, 1 \rangle$.

31. By rewriting the equation as $z = x^2 + y^2$, we recognize this as a paraboloid opening upward about the z -axis, with circular cross-sections.

32. By rewriting the equation as $z = x^2 - y^2$, we recognize this as a hyperbolic paraboloid. We can obtain further information about the graph by considering the traces at $x = 0$ and $y = 0$. When $x = 0$, we have the equation $z = -y^2$, which is a downward-facing parabola. When $y = 0$, we have the equation $z = x^2$, which is an upward-facing parabola.

33. We manipulate algebraically the given equation:

$$\begin{aligned} z = f(x, y) &= \sqrt{4 - x^2 - y^2} \\ z^2 &= 4 - x^2 - y^2 \\ x^2 + y^2 + z^2 &= 4 \end{aligned}$$

which we recognize as a sphere of radius 2 centered at the origin. However, because the original function is a square root, which produces only nonnegative values, this is the portion of the sphere with only nonnegative z -values, or the top half. Therefore, this is the top half of the sphere of radius 2 centered at the origin.

34. We manipulate algebraically the given equation:

$$\begin{aligned} z = f(x, y) &= \sqrt{x^2 + y^2 - 4} \\ z^2 &= x^2 + y^2 - 4 \\ x^2 + y^2 - z^2 &= 4 \end{aligned}$$

which we recognize as a hyperboloid of one sheet with its center at the origin, opening about the z -axis. However, because the original function is a square root, which produces only nonnegative values, this is the portion of the hyperboloid with only nonnegative z -values, or the top half.

35. We see that the variable x does not appear in the expression for the function, and so it is an unrestricted variable. We therefore first consider the behavior in only y and z , which is the curve $z = \sin y$. This is a graph of the sine function with y as the independent variable and z as the dependent variable. We then extend this curve in the x direction.

36. We see that the variable y does not appear in the expression for the function, and so it is an unrestricted variable. We therefore first consider the behavior in only x and z , which is the curve $z = \cos x$. This is a graph of the cosine function with x as the independent variable and z as the dependent variable. We then extend this curve in the y direction.

37. By rewriting the equation as $z = 4 - x^2 - y^2 = 4 - (x^2 + y^2)$, we recognize this as a paraboloid opening downward about the z -axis, with circular cross-sections, with vertex at height 4 above the xy -plane.

38. By rewriting the equation as $z = x^2 + y^2 - 4$, we recognize this as a paraboloid opening upward about the z -axis, with circular cross-sections, with vertex at height -4 below the xy -plane.

39. (a) We set $z = c$, and we get $c = x^2 - y^2$, which is equivalent to $\frac{x^2}{c} - \frac{y^2}{c} = 1$, provided that $c \neq 0$. We recognize these equations; their graphs are hyperbolas. For $c > 0$, they open about the x -axis. So, the level curves corresponding to $c = 1, 4, 9$ are hyperbolas opening about the x -axis. For $c = 0$, the equation becomes $x^2 = y^2$, or $y = \pm x$, so the level curve consists of two intersecting lines, whose slopes are 1 and -1 .

- (b) The graph is:

40. (a) We set $z = c$, and we get $c = 2x^2 + y^2$, which is equivalent to $\frac{x^2}{\frac{c}{2}} + \frac{y^2}{c} = 1$, provided that $c \neq 0$. We recognize these equations; their graphs are ellipses centered at the origin. So, the level curves corresponding to $c = 1, 4, 9$ are ellipses centered at the origin. For $c = 0$, the equation becomes $2x^2 + y^2 = 0$, which has only one solution, $x = 0$ and $y = 0$, so the level curve consists of one point, the origin.

- (b) The graph is:

41. (a) We set $z = c$, and we get $c = \sqrt{9 - x^2 - y^2}$, which is equivalent to $c^2 = 9 - x^2 - y^2$, or $x^2 + y^2 = 9 - c^2$. We recognize these as the equations of circles centered at the origin, with radius 3 for $c = 0$ and radius $\sqrt{8}$ for $c = 1$. For $c = 3$, the equation becomes $x^2 + y^2 = 0$, so the level curve consists of one point, the origin.

(b) The graph is:

42. (a) We set $z = c$, and we get $c = \sqrt{x^2 + y^2 - 4}$, which is equivalent to $c^2 = x^2 + y^2 - 4$, or $x^2 + y^2 = c^2 + 4$. We recognize these as the equations of circles centered at the origin, with radius 2 for $c = 0$, radius $\sqrt{5}$ for $c = 1$, radius $\sqrt{20}$ for $c = 4$ and radius $\sqrt{85}$ for $c = 9$.

(b) The graph is:

43. (a) We set $z = c$, and we get $c = x^2 - 2y$, which is equivalent to $2y = x^2 - c$, or $y = \frac{x^2}{2} - \frac{c}{2}$. For $c = 0$, this is the equation of a parabola that opens about the positive y -axis, with vertex at the origin. For $c = -4, -1, 1, 4$, this is the equation of the same parabola, translated up 2 units, up $\frac{1}{2}$ unit, down $\frac{1}{2}$ unit, and down 2 units (respectively).

(b) The graph is:

44. (a) We set $z = c$, and we get $c = y^2 - x$, which is equivalent to $x = y^2 - c$. For $c = 0$, this is the equation of a parabola that opens about the positive x -axis, with vertex at the origin. For $c = -4, -1, 1, 4$, this is the equation of the same parabola, translated right 4 units, right 1 unit, left 1 unit, and left 4 units (respectively).

(b) The graph is:

45. (a) We set $z = c$, and we get $c = x + \sin y$, which is equivalent to $x = -\sin y + c$. For $c = 0$, this is the equation of a sinusoidal curve; for $c = 2, 4, 8$, this is the equation of the same curve, translated right 2, 4 and 8 units respectively.

(b) The graph is:

46. (a) We set $z = c$, and we get $c = y - \ln x$, which is equivalent to $y = \ln x + c$. So the level curves are just translations of the graph of $y = \ln x$, up by 1, 2 and 4 units for $c = 1, 2$ and 4 (respectively).

(b) The graph is:

47. (a) We consider surfaces of the form $f(x, y, z) = c = x^2 + z^2$, where c is a constant (which in this case, cannot be negative since $x^2 + z^2 \geq 0$ for all x, z). We observe that the variable y is an unrestricted variable, and $c = x^2 + z^2$ forms a circle in x and z , centered about the y -axis. $c = x^2 + z^2$ is therefore a cylinder about the y -axis, and the level surfaces are such cylinders of increasing radii as c increases.
- (b) Shown is the level surface for $c = 3$.

(c) Yes.

48. (a) We consider surfaces of the form $f(x, y, z) = c = x^2 + y^2$, where c is a constant (which in this case, cannot be negative since $x^2 + y^2 \geq 0$ for all x, y). We observe that the variable z is an unrestricted variable, and $c = x^2 + y^2$ forms a circle in x and y , centered about the z -axis. $c = x^2 + y^2$ is therefore a cylinder about the z -axis, and the level surfaces are such cylinders of increasing radii as c increases.

(b) Shown is the level surface for $c = 4$.

(c) Yes.

49. (a) We consider surfaces of the form $f(x, y, z) = c = z - 2x - 2y$, where c is a constant. We observe that this surface forms a plane perpendicular to the vector $\langle -2, -2, 1 \rangle$. We can rewrite this surface as $z = 2x + 2y + c$, from which we can see that increasing values of c increase the z -intercept of the plane (i.e. move it up).

(b) Shown is the level surface for $c = -2$.

(c) Yes.

50. (a) We consider surfaces of the form $f(x, y, z) = c = x + y - z$, where c is a constant. We observe that this surface forms a plane perpendicular to the vector $\langle 1, 1, -1 \rangle$. We can rewrite this surface as $z = x + y - c$, from which we can see that increasing values of c decrease the z -intercept of the plane (i.e. move it down).

- (b) Shown is the level surface for $c = -1$.

- (c) Yes.

51. (a) We consider surfaces of the form $f(x, y, z) = c = 4 - x^2 - y^2$, where c is a constant. We observe that the variable z is an unrestricted variable, and rearrange our equation to obtain $x^2 + y^2 = 4 - c$. We see that since $x^2 + y^2 \geq 0$ for all x, y , we must have $4 - c \geq 0$ or $c \leq 4$. We see that for such c , this forms a circle in x and y (of radius $\sqrt{4 - c}$), centered about the z -axis. $x^2 + y^2 = 4 - c$ is therefore a cylinder about the z -axis for $c < 4$, and in this case the level surfaces are such cylinders of decreasing radii as c increases. $c = 4$ is a special case, as this yields $x^2 + y^2 = 0$, which is satisfied only by the point $(0, 0)$. So, the level surface is just the origin itself for $c = 4$.
- (b) Shown are the level surface for $c = 0$, and $c = 4$.

- (c) Yes.

52. (a) We consider surfaces of the form $f(x, y, z) = c = z$, where c is a constant. We observe that this surface is a plane parallel to the xy -plane, at height c above (or below) the xy -plane. Increasing values of c increase the height of the plane above the xy -plane (negative values of c will place the plane below the xy -plane).
- (b) Shown is the level surface for $c = \pi$.

(c) Yes.

Applications and Extensions

53. It appears that the contour lines are straight lines. To gain more information, we consider the curves of the form $f(x, y) = c = 2x - y - 2$, and manipulate this equation algebraically.

$$\begin{aligned}c &= 2x - y - 2 \\y &= 2x - 2 - c\end{aligned}$$

We can see that the level curves in the xy -plane are then lines of slope 2, with y -intercept $-2 - c$. This intercept decreases as c increases. This corresponds to graph **F**.

54. It appears that the contour lines are straight lines. To gain more information, we consider the curves of the form $f(x, y) = c = x + y - 3$, and manipulate this equation algebraically.

$$\begin{aligned}c &= x + y - 3 \\y &= -x + 3 + c\end{aligned}$$

We can see that the level curves in the xy -plane are then lines of slope -1 , with y -intercept $3 + c$. This intercept increases as c increases. This corresponds to graph **D**.

55. The contour lines appear to be ellipses centered at the origin; we verify algebraically. We set $f(x, y) = c = 4x^2 + y^2$, and further manipulate the equation:

$$\begin{aligned}c &= 4x^2 + y^2 \\1 &= \frac{4x^2}{c} + \frac{y^2}{c} \quad \text{for } c \neq 0 \\1 &= \frac{x^2}{\frac{c}{4}} + \frac{y^2}{c}\end{aligned}$$

We see then that for $c \neq 0$, the level curves in the xy -plane will indeed be ellipses centered at the origin (for $c = 0$ we have just the point $(0,0)$); as c increases, so will both the semi-major and semi-minor axes. This matches graph **B**.

56. It appears that the horizontal cross-sections, or contour lines of the cone are concentric circles with increasing radii as z increases. However, we verify this algebraically by considering constant values of $z = f(x, y)$, or $c = f(x, y)$:

$$\begin{aligned}c = f(x, y) &= \sqrt{\frac{x^2}{4^2} + \frac{y^2}{4^2}} = \sqrt{\frac{x^2}{16} + \frac{y^2}{16}} \\c^2 &= \frac{x^2}{16} + \frac{y^2}{16} \\16c^2 &= x^2 + y^2\end{aligned}$$

We see that as $|c|$ increases, we will have circles of increasing radii, centered at the origin. This corresponds to graph **C**.

57. The contour lines appear to be hyperbolas opening about the x -axis or y -axis, centered at the origin. We verify algebraically by manipulating the equation $f(x, y) = c = \frac{x^2}{2^2} - \frac{y^2}{1^2}$:

$$\begin{aligned} c &= \frac{x^2}{2^2} - \frac{y^2}{1^2} \\ 1 &= \frac{x^2}{4c} - \frac{y^2}{c} \quad \text{if } c \neq 0 \end{aligned}$$

These are indeed hyperbolas with the x -axis as the transverse axis if $c > 0$ and the y -axis if $c < 0$. As c increases, the eccentricity decreases. If $c = 0$, the level curve is given by $0 = \frac{x^2}{2^2} - \frac{y^2}{1^2}$, which is satisfied by only the origin. This corresponds to graph A.

58. The contour lines appear to be pairs of hyperbolas centered at the origin. We will not be able to easily see this algebraically, but we do see that horizontal planes will cut the surface at hyperbolas with asymptotes given by combinations of the x - and y -axes and the lines $y = \pm x$. This helps us recognize the corresponding graph of level curves as E.
59. (a) Four Corners is about halfway between two isotherms, one with temperature $45^\circ F$ and one with temperature $50^\circ F$, and seems slightly closer to the $45^\circ F$ isotherm. Therefore, an estimate for the temperature at Four Corners would be 47° F.
- (b) When we move south from the Four Corners, we move from a point with approximate temperature $47^\circ F$ in the direction of the isotherm with temperature $50^\circ F$, which means that the temperature will be increasing.
- (c) To move as quickly to the next warmer temperature zone, we would move toward the isotherm with temperature $50^\circ F$. Therefore, we would move toward the southwest. Regarding how the path intersects the isotherm, answers will vary.
- (d) Answers will vary.
60. (a) Examining the level curves, we see that the altitude at point A is almost 1770 feet. At the other three points, the altitude is below 1730 feet. So, she would start to climb at point A to minimize the distance climbed.
- (b) The climb would be initially the steepest at point D, because the level curves are closest at that point.
- (c) The climber would walk along the level curve, since the level curve is by definition the curve along which the altitude is constant.
- (d) Answers will vary.
61. (a) We take $M = 10$ and $C = 12$, so $IQ = 100 \cdot \frac{10}{12} \approx$ 83.
- (b) We take $M = 12$ and $C = 10$, so $IQ = 100 \cdot \frac{12}{10} =$ 120.
- (c) We take $IQ = 139$ and $C = 10$, and we solve for M : $139 = 100 \cdot \frac{M}{10}$, so $139 = 10M$, and $M = \frac{139}{10} \approx$ 14.
62. Since x is the number of megabytes used domestically in excess of 200, and the total number of megabytes used domestically is equal to 210, we see that $x = 210 - 200$, so $x = 10$. Since y is the number of kilobytes used to or from Canada, we see that $y = 250$.

Since z is the number of kilobytes used outside the United States and Canada, we see that $z = 15$. Therefore, the monthly cost (in dollars) is

$$C(10, 250, 15) = 35.00 + 0.1(10) + 0.015(250) + 0.0195(15) = 40.0425,$$

which rounds to $\boxed{\$40.04}$.

63. (a) $A(3, 4) = 9 \left(\frac{3}{4} \right) = \boxed{6.75}$.
 (b) $A(6, 3) = 9 \left(\frac{6}{3} \right) = \boxed{18}$.
 (c) $A(2, 9) = 9 \left(\frac{2}{9} \right) = \boxed{2}$.
 (d) $A(3, 18) = 9 \left(\frac{3}{18} \right) = \boxed{1.5}$.
64. (a) s is the total number of field goals attempted. Since he attempted 488 two-point field goals and zero three-point field goals, we have $s = 488 + 0 = 488$. Since he attempted zero three-point field goals, he made zero three-point field goals, so $y = 0$. Also, we are told that he made 234 two-point field goals, so $x = 234$. Therefore, his adjusted field goal percentage is $f(234, 0, 488) = \frac{234 + 1.5(0)}{488} \approx \boxed{.480}$.
- (b) s is the total number of field goals attempted. Since he attempted 527 two-point field goals and 246 three-point field goals, we have $s = 527 + 246 = 773$. Since he made 234 three-point field goals, we have $y = 234$. Also, we are told that he made 234 two-point field goals, so $x = 234$. Therefore, his adjusted field goal percentage is $f(234, 234, 773) = \frac{234 + 1.5(234)}{773} \approx \boxed{.757}$.
65. (a) We have $r = 50$ and $t = 95$, so the heat index is given by

$$\begin{aligned} H(95, 50) &= -42.379 + (2.04901523)(95) + (10.1333127)(50) - (0.22475541)(95)(50) \\ &\quad - (0.00683783)(95)^2 - (0.05481717)(50)^2 + (0.00122874)(95)^2(50) \\ &\quad + (0.00085282)(95)(50)^2 - (0.00000199)(95)^2(50)^2 \approx 104.715, \end{aligned}$$

so we have a heat index of approximately $\boxed{104.715^\circ F}$.

- (b) We have $H(t, r) = 105$ and $t = 97$, and we need to solve for r . We have:

$$\begin{aligned} 105 &= -42.379 + (2.04901523)(97) + (10.1333127)r - (0.22475541)(97)r \\ &\quad - (0.00683783)(97)^2 - (0.05481717)r^2 + (0.00122874)(97)^2r \\ &\quad + (0.00085282)(97)r^2 - (0.00000199)(97)^2r^2 \\ &= 92.03833484 - 0.10674741r + 0.00918246r^2. \end{aligned}$$

So we have a quadratic equation for r :

$$0.00918246r^2 - 0.10674741r - 12.96166516 = 0.$$

Solving using the quadratic formula, we get

$$\begin{aligned} r &= \frac{0.10674741 \pm \sqrt{(-0.10674741)^2 - 4(0.00918246)(-12.96166516)}}{2(0.00918246)} \\ &\approx \frac{0.10674741 \pm 0.698194025}{0.01836492}. \end{aligned}$$

But the negative square root will result in a negative value for r , which makes no sense, so we will take the positive square root.

$r \approx \frac{0.10674741 + 0.698194025}{0.01836492} \approx 43.830$. So, there is only one value for the relative humidity that will result in a heat index of $105^\circ F$, and that value is approximately 43.830%. Since this is the *only* such value, it must be the minimum such value; therefore, the minimum relative humidity that will result in a heat index of $105^\circ F$ is $\boxed{\approx 43.830\%}$.

66. (a) $Q(19, 21) = 400(19)^{0.3}(21)^{0.7} \approx \boxed{8151.538}$.
 (b) $Q(21, 20) = 400(21)^{0.3}(20)^{0.7} \approx \boxed{8117.958}$.
67. The surface of an open box consists of five rectangles. One of them is the base of the box; it is an x by y rectangle, so its area is xy . Two of the sides of the box are x by z rectangles; their area is xz (each). The other two sides of the box are y by z rectangles; their area is yz (each). So we arrive at the total surface area of the open box, which is $\boxed{S(x, y, z) = xy + 2xz + 2yz}$.
68. The bottom and top of the tank are circles of radius R , so their area is πR^2 (each). This means that the cost of the bottom and the top will be $300\pi R^2$ dollars each, or $600\pi R^2$ total. The side of the tank has area equal to the surface area of the cylinder, or $2\pi Rh$, and the cost is $500 \cdot 2\pi Rh$ dollars, or $1000\pi Rh$ dollars. Therefore, the total cost of constructing the tank, in dollars, is $\boxed{C(R, h) = 600\pi R^2 + 1000\pi Rh}$.
69. Denote the length of the box by x , its width by y and its depth by z . Here, x , y and z are in centimeters. The bottom of the box is an x by y rectangle, so its area is xy and its cost is $4xy$. Two of the sides are x by z rectangles, and the other two are y by z rectangles; we will assume that the former are more expensive. So, the more expensive sides have area xz each, so their cost is $3xz$ each, or $6xz$ total. The less expensive sides have area yz each, so their cost is $2yz$ each, or $4yz$ total. So, the total cost of constructing the open box, in dollars, is $\boxed{C(x, y, z) = 4xy + 6xz + 4yz}$.
70. Denote the length of the box by x , its width by y and its depth by z . Here, x , y and z are in centimeters. The bottom of the box is an x by y rectangle, so its area is xy and its cost is $4xy$. The top of the box is also an x by y rectangle, so its area is also xy and its cost is $5xy$. Two of the sides are x by z rectangles, and the other two are y by z rectangles; we will assume that the former are more expensive. So, the more expensive sides have area xz each, so their cost is $3xz$ each, or $6xz$ total. The less expensive sides have area yz each, so their cost is $2yz$ each, or $4yz$ total. So, the total cost of constructing the closed box, in dollars, is $C(x, y, z) = 4xy + 5xy + 6xz + 4yz$, or $\boxed{C(x, y, z) = 9xy + 6xz + 4yz}$.
71. We see the level curves for $V = 18, 9$, and 6 below. The surface described by $z = V(x, y)$ exists only for (x, y) such that (x, y) is in the domain of V , and V has domain consisting of all (x, y) such that $4 - (x^2 + y^2) > 0$, or $x^2 + y^2 < 4$. This is the interior of the circle of radius 2 centered at the origin. So, the surface exists only above this disc. Also, note that a square root always produces a nonnegative output, so $V > 0$ always, and so it exists above the disc as opposed to below. Lastly, note that as distance from the origin ($x^2 + y^2$) increases, the denominator of V decreases, making V increase. So, $V(0, 0) = \frac{9}{2}$ and the z -values increase without bound as we move away from the origin, and asymptotically approach the circle $x^2 + y^2 = 4$.

72. We see the level curves for $T = 60^\circ, 54^\circ, 48^\circ, 6^\circ$, and 0° below. The surface described by $z = T(x, y)$ is an elliptic paraboloid opening downward, shifted up 60 units (degrees) on the z -axis.

73. We consider surfaces of the form $E(x, y, z) = c = \frac{3}{\sqrt{y^2 + z^2}}$. We then perform some algebraic manipulation on this equation:

$$\begin{aligned} c &= \frac{3}{\sqrt{y^2 + z^2}} \\ c^2 &= \frac{9}{y^2 + z^2} \\ y^2 + z^2 &= \frac{9}{c^2} \end{aligned}$$

We see that these are cylinders with the x -axis going through them, of radius $\frac{3}{c}$. (Note that c must be positive to begin with since $\sqrt{y^2 + z^2} \geq 0$ and $\frac{3}{\sqrt{y^2 + z^2}} \neq 0$ for all y, z .) The radii decrease as c increases.

The level surfaces for $E(x, y, z)$ are all cylinders of differing radii with the x -axis going through them.

74. We consider surfaces of the form $F(x, y, z) = c = \frac{GmM}{x^2 + y^2 + z^2}$, and perform some algebraic manipulation on this equation:

$$\begin{aligned} c &= \frac{GmM}{x^2 + y^2 + z^2} \\ x^2 + y^2 + z^2 &= \frac{GmM}{c^2} \end{aligned}$$

We see that these are spheres centered at the origin of radius $\frac{\sqrt{GmM}}{c}$. (Once again note that $c > 0$ since $G, m, M, x^2 + y^2 + z^2 \geq 0$ and $\frac{GmM}{x^2 + y^2 + z^2} \neq 0$ for all x, y, z .) The radii decrease as c increases.

75. (a) Because T is being held constant, we are considering T as our dependent variable, and examining the level curves of the function $T = f(P, V)$. This yields $T = c = f(P, V)$, or $PV = nRc$. If we solve for V , we can think of these curves as existing in the PV -plane. This yields $V = \frac{nRc}{P} = c \left(\frac{nR}{P} \right)$, which are hyperbolas (centered at the origin). Since c is multiplying the function $V = \frac{nR}{P}$, the hyperbolas will be increasing vertical stretches of this function, as c increases (as shown in the graph).

- (b) Because P is being held constant, we are considering P as our dependent variable, and examining the level curves of the function $P = f(T, V)$. This yields $P = c = f(T, V)$, or $cV = nRT$. If

we solve for V , we can think of these curves as existing in the TV -plane. This yields $V = \frac{nRT}{c}$, which are lines with V -intercept 0 and slope $\frac{nR}{c}$. The slopes will decrease as c increases, and the lines will approach vertical lines as c tends to 0.

- (c) Because V is being held constant, we are considering V as our dependent variable, and examining the level curves of the function $V = f(T, P)$. This yields $V = c = f(T, P)$, or $Pc = nRT$. If we solve for P , we can think of these curves as existing in the TP -plane. This yields $P = \frac{nRT}{c}$, which are lines with P -intercept 0 and slope $\frac{nR}{c}$. The slopes will decrease as c increases, and the lines will approach vertical lines as c tends to 0.

76. (a) We consider surfaces of the form $V = c = \frac{kQ}{\sqrt{x^2 + y^2 + z^2}}$. We manipulate this equation algebraically to better understand these surfaces:

$$\begin{aligned} c &= \frac{kQ}{\sqrt{x^2 + y^2 + z^2}} \\ c^2 &= \frac{k^2 Q^2}{x^2 + y^2 + z^2} \\ x^2 + y^2 + z^2 &= \frac{k^2 Q^2}{c^2} \end{aligned}$$

We see that these are spheres centered at the origin of radius $\frac{kQ}{c}$. The radii decrease as c increases.

- (b) We see that considering $V \rightarrow 0$ is equivalent to considering $c \rightarrow 0$ in the above equation of the sphere. As $c \rightarrow 0$, the radii of the spheres increase to infinity.

77. (a) We consider surfaces of the form $B = c = \frac{\mu_0 I}{2\pi\sqrt{x^2 + y^2}}$. We manipulate this equation algebraically to better understand these surfaces:

$$\begin{aligned} c &= \frac{\mu_0 I}{2\pi\sqrt{x^2 + y^2}} \\ c^2 &= \frac{\mu_0^2 I^2}{4\pi^2(x^2 + y^2)} \\ x^2 + y^2 &= \frac{\mu_0^2 I^2}{4\pi^2 c^2} \end{aligned}$$

We see that these are circular cylinders opening about the z -axis, of radius $\frac{\mu_0 I}{2\pi c}$. The radii decrease as c increases.

- (b) We see that considering what happens as $|B|$ increases to ∞ is equivalent to considering $|c| \rightarrow \infty$ in the above equation of the sphere. As $|c| \rightarrow \infty$, the radii of the cylinders decrease toward 0, and tend to the B -axis.

78. (a) We write the equation as $U = -\frac{GMm}{\sqrt{x^2 + y^2 + z^2}}$ for simplicity. We then consider surfaces of the form $U = c = \frac{GMm}{\sqrt{x^2 + y^2 + z^2}}$. We manipulate this equation algebraically to better understand these surfaces:

$$\begin{aligned} c &= -\frac{GMm}{\sqrt{x^2 + y^2 + z^2}} \\ c^2 &= \frac{G^2 M^2 m^2}{x^2 + y^2 + z^2} \\ x^2 + y^2 + z^2 &= \frac{G^2 M^2 m^2}{c^2} \end{aligned}$$

We see that these are spheres centered at the origin of radius $\frac{GMm}{|c|}$. (Note that $c < 0$ since

$c = -\frac{GMm}{\sqrt{x^2 + y^2 + z^2}}$.) The radii decrease as $|c|$ increases.

- (b) We see that considering $U \rightarrow 0$ is equivalent to considering $c \rightarrow 0$ in the above equation of the sphere. As $c \rightarrow 0$, the radii of the spheres increase to infinity.

79. (a) The graph is:

- (b) Answers will vary.

- (c) This is a version the graph that shows contour lines:

- (d) We set $f(x, y) = c$, and we obtain $c = 5e^{-x^2 - y^2}$, or $\frac{c}{5} = e^{-x^2 - y^2}$. Taking the natural logarithm of both sides, we get $\ln\left(\frac{c}{5}\right) = -x^2 - y^2$, or $x^2 + y^2 = \ln\left(\frac{5}{c}\right)$. So the level curve $f(x, y) = c$ is a circle of radius $\sqrt{\ln\left(\frac{5}{c}\right)}$ centered at the origin.

(e) Answers will vary.

80. (a) We manipulate the equation $z = \frac{1}{3}(x^2 + y^2)$ to obtain $x^2 + y^2 = 3z$, and replace $x^2 + y^2$ with $3z$ in the equation $x^2 + y^2 + z^2 = 4$ to obtain $3z + z^2 = 4$. We solve for z :

$$\begin{aligned} z^2 + 3z - 4 &= 0 \\ (z + 4)(z - 1) &= 0 \end{aligned}$$

from which we obtain the horizontal planes $z = -4$ and $z = 1$, the latter of which is above the xy -plane. So, the desired curve of intersection is at height $z = 1$, which we substitute into $x^2 + y^2 = 3z$ to obtain $x^2 + y^2 = 3$. This is a circle in the plane $z = 1$ of radius $\sqrt{3}$, centered at $(0, 0, 1)$.

(b) The graphs are:

(c) Yes.

81. The level curves of $f(x, y)$ will be surfaces of the form $f(x, y) = c = x^2 - y^2$, or $1 = \frac{x^2}{c} - \frac{y^2}{c}$. These are symmetric hyperbolas centered about the origin, with asymptotes of $y = \pm x$. The level curves of $g(x, y)$ will be surfaces of the form $g(x, y) = k = xy$, or $y = \frac{k}{x}$. These are also hyperbolas with asymptotes of the x - and y -axes.

82. We consider the level curves of the graphs of f and g through P_0 , which can be represented by $c_1 = x^2 - y^2$ and $c_2 = xy$ respectively, for some constants c_1 and c_2 . We will compare the slopes of these curves at P_0 . We do this by implicitly differentiating each equation with respect to x :

$$\begin{aligned}\frac{d}{dx}(c_1) &= \frac{d}{dx}(x^2 - y^2) \\ 0 &= \frac{d}{dx}(x^2) - \frac{d}{dx}(y^2) \\ 0 &= 2x - 2y \frac{dy}{dx} \\ \frac{dy}{dx} &= \frac{x}{y}\end{aligned}$$

and

$$\begin{aligned}\frac{d}{dx}(c_2) &= \frac{d}{dx}(xy) \\ 0 &= y + x \frac{dy}{dx} \quad \text{product rule} \\ \frac{dy}{dx} &= -\frac{y}{x}\end{aligned}$$

We see that these derivatives hold for all $(x, y) \neq (0, 0)$, and that they are opposite reciprocals of each other. So, the curves are perpendicular at any point $P_0 \neq (0, 0)$.

Challenge Problems

83. We know that the set of points (x, y, z) satisfying the condition $x^2 + y^2 + z^2 < 1$ is the region inside the unit sphere centered at the origin.

We also know that the set of points (x, y, z) satisfying the condition $x^2 + y^2 = z^2$ is a circular cone whose vertex is at the origin.

Therefore, the set of points satisfying the condition $x^2 + y^2 < z^2$, where $z > 0$, is the region located above the upper nappe of that circular cone.

The set of points described in the problem is the region that is both inside the unit sphere and above the upper nappe of the circular cone.

It is the inside of the region portrayed here:

Chapter 12: Functions of Several Variables

12.2: Limits and Continuity

Concepts and Vocabulary

1. **c, a δ -neighborhood**. A δ -neighborhood of P_0 consists of all the points P that lie within a distance δ of P_0 .
2. $\lim_{(x,y) \rightarrow (1,8)} 2y = 2 \left[\lim_{(x,y) \rightarrow (1,8)} y \right] = 2 \lim_{y \rightarrow 8} y = 2(8) = \mathbf{16}$.
3. **False**. For $\lim_{(x,y) \rightarrow (0,0)} f(x,y)$ to exist and equal L , it must exist and equal L along *all* curves in the domain of f that contain $(0,0)$, not just the straight-line curves.
4. **True**. This follows from the discussion in the beginning of subsection 3.
5. **c, a boundary**. See definition of “boundary point”.
6. **a, open**. See definition of “open”.
7. **False**. If $f(P_0) = 0$, then $\frac{g}{f}$ is not continuous at P_0 .
8. Since the function is continuous at $(0,0)$, we can evaluate it at $(0,0)$ to find the limit:

$$\lim_{(x,y) \rightarrow (0,0)} e^{x^2+y^2} = e^{0+0} = e^0 = \boxed{1}.$$

Skill Building

9. We use algebraic properties of limits:

$$\begin{aligned} \lim_{(x,y) \rightarrow (1,2)} x^2 + xy - y^2 + 8 &= \lim_{(x,y) \rightarrow (1,2)} x^2 + \lim_{(x,y) \rightarrow (1,2)} xy - \lim_{(x,y) \rightarrow (1,2)} y^2 + \lim_{(x,y) \rightarrow (1,2)} 8 \\ &= \lim_{x \rightarrow 1} x^2 + \left(\lim_{x \rightarrow 1} x \right) \left(\lim_{y \rightarrow 2} y \right) - \lim_{y \rightarrow 2} y^2 + 8 \\ &= 1 + 1 \cdot 2 - 4 + 8 = \boxed{7}. \end{aligned}$$

10. We use algebraic properties of limits:

$$\begin{aligned} &\lim_{(x,y) \rightarrow (-1,3)} x^2y + y^2 - 3xy - 2 \\ &= \lim_{(x,y) \rightarrow (-1,3)} x^2y + \lim_{(x,y) \rightarrow (-1,3)} y^2 - \lim_{(x,y) \rightarrow (-1,3)} 3xy - \lim_{(x,y) \rightarrow (-1,3)} 2 \\ &= \left(\lim_{x \rightarrow -1} x^2 \right) \left(\lim_{y \rightarrow 3} y \right) + \lim_{y \rightarrow 3} y^2 - 3 \left(\lim_{x \rightarrow -1} x \right) \left(\lim_{y \rightarrow 3} y \right) - 2 \\ &= 1 \cdot 3 + 9 - 3 \cdot (-1) \cdot 3 - 2 = \boxed{19}. \end{aligned}$$

11. We use algebraic properties of limits:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (1,-1,2)} (3x^2y + y^2z) &= \lim_{(x,y,z) \rightarrow (1,-1,2)} (3x^2y) + \lim_{(x,y,z) \rightarrow (1,-1,2)} (y^2z) \\ &= 3 \left(\lim_{x \rightarrow 1} x^2 \right) \left(\lim_{y \rightarrow -1} y \right) + \left(\lim_{y \rightarrow -1} y^2 \right) \left(\lim_{z \rightarrow 2} z \right) \\ &= 3 \cdot 1 \cdot (-1) + 1 \cdot 2 = \boxed{-1}. \end{aligned}$$

12. We use algebraic properties of limits:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,1,-1)} (x^2 - y^2z^2) &= \lim_{(x,y,z) \rightarrow (0,1,-1)} x^2 - \lim_{(x,y,z) \rightarrow (0,1,-1)} (y^2z^2) \\ &= \lim_{x \rightarrow 0} x^2 - \left(\lim_{y \rightarrow 1} y^2 \right) \left(\lim_{z \rightarrow -1} z^2 \right) \\ &= 0 - 1 \cdot 1 = \boxed{-1}. \end{aligned}$$

13. We use algebraic properties of limits:

$$\lim_{(x,y) \rightarrow (\frac{\pi}{2}, \pi)} \sin x \cos y = \left(\lim_{x \rightarrow \frac{\pi}{2}} \sin x \right) \left(\lim_{y \rightarrow \pi} \cos y \right) = \sin \frac{\pi}{2} \cos \pi = 1 \cdot -1 = \boxed{-1}.$$

14. We use algebraic properties of limits:

$$\lim_{(x,y) \rightarrow (2,e)} x^2y \ln y = \left(\lim_{x \rightarrow 2} x^2 \right) \left(\lim_{y \rightarrow e} y \right) \left(\lim_{y \rightarrow e} \ln y \right) = 4 \cdot e \cdot \ln(e) = 4 \cdot e \cdot 1 = \boxed{4e}.$$

15. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (1,5)} 4y - y^2 = \lim_{(x,y) \rightarrow (1,5)} 4y - \lim_{(x,y) \rightarrow (1,5)} y^2 = 4 \cdot \lim_{y \rightarrow 5} y - \lim_{y \rightarrow 5} y^2 = 4 \cdot 5 - 25 = -5 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
\lim_{(x,y) \rightarrow (1,5)} 4x - xy + 4 &= \lim_{(x,y) \rightarrow (1,5)} 4x - \lim_{(x,y) \rightarrow (1,5)} xy + \lim_{(x,y) \rightarrow (1,5)} 4 \\
&= 4 \cdot \lim_{x \rightarrow 1} x - \left(\lim_{x \rightarrow 1} x \right) \left(\lim_{y \rightarrow 5} y \right) + 4 \\
&= 4 \cdot 1 - 1 \cdot 5 + 4 = 3.
\end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (1,5)} \frac{4x - xy + 4}{4y - y^2} = \frac{\lim_{(x,y) \rightarrow (1,5)} 4x - xy + 4}{\lim_{(x,y) \rightarrow (1,5)} 4y - y^2} = \frac{3}{-5} = \boxed{-\frac{3}{5}}.$$

16. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (2,2)} x + y - 3 = \lim_{(x,y) \rightarrow (2,2)} x + \lim_{(x,y) \rightarrow (2,2)} y - \lim_{(x,y) \rightarrow (2,2)} 3 = \lim_{x \rightarrow 2} x + \lim_{y \rightarrow 2} y - 3 = 2 + 2 - 3 = 1 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
\lim_{(x,y) \rightarrow (2,2)} x^2 + 2xy + y^2 - 9 &= \lim_{(x,y) \rightarrow (2,2)} x^2 + \lim_{(x,y) \rightarrow (2,2)} 2xy + \lim_{(x,y) \rightarrow (2,2)} y^2 - \lim_{(x,y) \rightarrow (2,2)} 9 \\
&= \lim_{x \rightarrow 2} x^2 + 2 \left(\lim_{x \rightarrow 2} x \right) \left(\lim_{y \rightarrow 2} y \right) + \lim_{y \rightarrow 2} y^2 - 9 \\
&= 4 + 2 \cdot 2 \cdot 2 + 4 - 9 = 7.
\end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (2,2)} \frac{x^2 + 2xy + y^2 - 9}{x + y - 3} = \frac{\lim_{(x,y) \rightarrow (2,2)} x^2 + 2xy + y^2 - 9}{\lim_{(x,y) \rightarrow (2,2)} x + y - 3} = \frac{7}{1} = \boxed{7}.$$

17. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (\pi,0)} x = \lim_{x \rightarrow \pi} x = \pi \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\lim_{(x,y) \rightarrow (\pi,0)} \cos x \cos y = \left(\lim_{x \rightarrow \pi} \cos x \right) \left(\lim_{y \rightarrow 0} \cos y \right) = \cos \pi \cdot \cos 0 = -1 \cdot 1 = -1.$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (\pi,0)} \frac{\cos x \cos y}{x} = \frac{\lim_{(x,y) \rightarrow (\pi,0)} \cos x \cos y}{\lim_{(x,y) \rightarrow (\pi,0)} x} = \frac{-1}{\pi} = \boxed{-\frac{1}{\pi}}.$$

18. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (\pi,\pi)} xy = \left(\lim_{x \rightarrow \pi} x \right) \left(\lim_{y \rightarrow \pi} y \right) = \pi \cdot \pi = \pi^2 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
 \lim_{(x,y) \rightarrow (\pi,\pi)} \cos y(1 - \cos x) &= \left(\lim_{y \rightarrow \pi} \cos y \right) \left(\lim_{x \rightarrow \pi} (1 - \cos x) \right) \\
 &= \left(\lim_{y \rightarrow \pi} \cos y \right) \left(\lim_{x \rightarrow \pi} 1 - \lim_{x \rightarrow \pi} \cos x \right) \\
 &= \cos \pi (1 - \cos \pi) = (-1) \cdot (1 - (-1)) = -2.
 \end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (\pi,\pi)} \frac{\cos y(1 - \cos x)}{xy} = \frac{\lim_{(x,y) \rightarrow (\pi,\pi)} \cos y(1 - \cos x)}{\lim_{(x,y) \rightarrow (\pi,\pi)} xy} = \frac{-2}{\pi^2} = \boxed{-\frac{2}{\pi^2}}.$$

19. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (0,0)} e^y = \lim_{y \rightarrow 0} e^y = e^0 = 1 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\lim_{(x,y) \rightarrow (0,0)} e^x - 4 = \lim_{(x,y) \rightarrow (0,0)} e^x - \lim_{(x,y) \rightarrow (0,0)} 4 = \lim_{x \rightarrow 0} e^x - 4 = e^0 - 4 = 1 - 4 = -3.$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{e^x - 4}{e^y} = \frac{\lim_{(x,y) \rightarrow (0,0)} e^x - 4}{\lim_{(x,y) \rightarrow (0,0)} e^y} = \frac{-3}{1} = \boxed{-3}.$$

20. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (0,0)} e^y = e^0 = 1 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
 \lim_{(x,y) \rightarrow (0,0)} e^x \cos y - \cos y &= \lim_{(x,y) \rightarrow (0,0)} e^x \cos y - \lim_{(x,y) \rightarrow (0,0)} \cos y \\
 &= \left(\lim_{x \rightarrow 0} e^x \right) \left(\lim_{y \rightarrow 0} \cos y \right) - \lim_{y \rightarrow 0} \cos y \\
 &= e^0 \cdot \cos 0 - \cos 0 = 1 \cdot 1 - 1 = 0.
 \end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{e^x \cos y - \cos y}{e^y} = \frac{\lim_{(x,y) \rightarrow (0,0)} e^x \cos y - \cos y}{\lim_{(x,y) \rightarrow (0,0)} e^y} = \frac{0}{1} = \boxed{0}.$$

21. Look at the denominator. Since

$$\begin{aligned}
 \lim_{(x,y) \rightarrow (2,1)} x^2 + 4y^2 &= \lim_{(x,y) \rightarrow (2,1)} x^2 + \lim_{(x,y) \rightarrow (2,1)} 4y^2 \\
 &= \lim_{x \rightarrow 2} x^2 + 4 \cdot \lim_{y \rightarrow 1} y^2 = 4 + 4 \cdot 1 = 8 \neq 0,
 \end{aligned}$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
\lim_{(x,y) \rightarrow (2,1)} x^2 + xy - 6y^2 &= \lim_{(x,y) \rightarrow (2,1)} x^2 + \lim_{(x,y) \rightarrow (2,1)} xy - \lim_{(x,y) \rightarrow (2,1)} 6y^2 \\
&= \lim_{x \rightarrow 2} x^2 + \left(\lim_{x \rightarrow 2} x \right) \left(\lim_{y \rightarrow 1} y \right) - 6 \cdot \lim_{y \rightarrow 1} y^2 \\
&= 4 + 2 \cdot 1 - 6 \cdot 1 = 0.
\end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (2,1)} \frac{x^2 + xy - 6y^2}{x^2 + 4y^2} = \frac{\lim_{(x,y) \rightarrow (2,1)} x^2 + xy - 6y^2}{\lim_{(x,y) \rightarrow (2,1)} x^2 + 4y^2} = \frac{0}{8} = \boxed{0}.$$

22. Look at the denominator. Since

$$\begin{aligned}
\lim_{(x,y) \rightarrow (0,-2)} xy - y + 2x - e^x &= \lim_{(x,y) \rightarrow (0,-2)} xy - \lim_{(x,y) \rightarrow (0,-2)} y + \lim_{(x,y) \rightarrow (0,-2)} 2x - \lim_{(x,y) \rightarrow (0,-2)} e^x \\
&= \left(\lim_{x \rightarrow 0} x \right) \left(\lim_{y \rightarrow -2} y \right) - \left(\lim_{y \rightarrow -2} y \right) + 2 \cdot \left(\lim_{x \rightarrow 0} x \right) - \left(\lim_{x \rightarrow 0} e^x \right) \\
&= 0 \cdot (-2) - (-2) + 2 \cdot 0 - e^0 = 0 + 2 + 0 - 1 = 1 \neq 0,
\end{aligned}$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
&\lim_{(x,y) \rightarrow (0,-2)} y^2 + xy + 4y + e^x \\
&= \lim_{(x,y) \rightarrow (0,-2)} y^2 + \lim_{(x,y) \rightarrow (0,-2)} xy + \lim_{(x,y) \rightarrow (0,-2)} 4y + \lim_{(x,y) \rightarrow (0,-2)} e^x \\
&= \lim_{y \rightarrow -2} y^2 + \left(\lim_{x \rightarrow 0} x \right) \left(\lim_{y \rightarrow -2} y \right) + 4 \cdot \left(\lim_{y \rightarrow -2} y \right) + \left(\lim_{x \rightarrow 0} e^x \right) \\
&= (-2)^2 + 0 \cdot (-2) + 4 \cdot (-2) + e^0 = 4 + 0 - 8 + 1 = -3.
\end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (0,-2)} \frac{y^2 + xy + 4y + e^x}{xy - y + 2x - e^x} = \frac{\lim_{(x,y) \rightarrow (0,-2)} y^2 + xy + 4y + e^x}{\lim_{(x,y) \rightarrow (0,-2)} xy - y + 2x - e^x} = \frac{-3}{1} = \boxed{-3}.$$

23. Look at the denominator. Since

$$\begin{aligned}
\lim_{(x,y) \rightarrow (2,0)} x^3 y + 3xy^2 - 8 &= \lim_{(x,y) \rightarrow (2,0)} x^3 y + \lim_{(x,y) \rightarrow (2,0)} 3xy^2 - \lim_{(x,y) \rightarrow (2,0)} 8 \\
&= \left(\lim_{x \rightarrow 2} x^3 \right) \left(\lim_{y \rightarrow 0} y \right) + 3 \cdot \left(\lim_{x \rightarrow 2} x \right) \left(\lim_{y \rightarrow 0} y^2 \right) - 8 \\
&= 8 \cdot 0 + 3 \cdot 2 \cdot 0 - 8 = -8 \neq 0,
\end{aligned}$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned}
\lim_{(x,y) \rightarrow (2,0)} x^2 y + x &= \lim_{(x,y) \rightarrow (2,0)} x^2 y + \lim_{(x,y) \rightarrow (2,0)} x \\
&= \left(\lim_{x \rightarrow 2} x^2 \right) \left(\lim_{y \rightarrow 0} y \right) + \lim_{x \rightarrow 2} x \\
&= 2^2 \cdot 0 + 2 = 0 + 2 = 2.
\end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (2,0)} \frac{x^2y + x}{x^3y + 3xy^2 - 8} = \frac{\lim_{(x,y) \rightarrow (2,0)} x^2y + x}{\lim_{(x,y) \rightarrow (2,0)} x^3y + 3xy^2 - 8} = \frac{2}{-8} = \boxed{-\frac{1}{4}}.$$

24. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (0,1)} xy + 4 = \lim_{(x,y) \rightarrow (0,1)} xy + \lim_{(x,y) \rightarrow (0,1)} 4 = \left(\lim_{x \rightarrow 0} x\right) \left(\lim_{y \rightarrow 1} y\right) + 4 = 0 \cdot 1 + 4 = 4 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,1)} x^3 - 4x^2y + 2 &= \lim_{(x,y) \rightarrow (0,1)} x^3 - \lim_{(x,y) \rightarrow (0,1)} 4x^2y + \lim_{(x,y) \rightarrow (0,1)} 2 \\ &= \lim_{x \rightarrow 0} x^3 - 4 \cdot \left(\lim_{x \rightarrow 0} x^2\right) \left(\lim_{y \rightarrow 1} y\right) + 2 \\ &= 0 - 4 \cdot 0 \cdot 1 + 2 = 2. \end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (0,1)} \frac{x^3 - 4x^2y + 2}{xy + 4} = \frac{\lim_{(x,y) \rightarrow (0,1)} x^3 - 4x^2y + 2}{\lim_{(x,y) \rightarrow (0,1)} xy + 4} = \frac{2}{4} = \boxed{\frac{1}{2}}.$$

25. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x \cdot 0}{2x^2 + 0} = \lim_{x \rightarrow 0} \frac{0}{2x^2} = \lim_{x \rightarrow 0} 0 = \boxed{0}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3 \cdot 0 \cdot y}{2 \cdot 0 + y^2} = \lim_{y \rightarrow 0} \frac{0}{y^2} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x \cdot x}{2x^2 + x^2} = \lim_{x \rightarrow 0} \frac{3x^2}{3x^2} = \lim_{x \rightarrow 0} 1 = \boxed{1}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x \cdot (3x)}{2x^2 + (3x)^2} = \lim_{x \rightarrow 0} \frac{9x^2}{2x^2 + 9x^2} = \lim_{x \rightarrow 0} \frac{9x^2}{11x^2} = \lim_{x \rightarrow 0} \frac{9}{11} = \boxed{\frac{9}{11}}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x \cdot x^2}{2x^2 + (x^2)^2} = \lim_{x \rightarrow 0} \frac{3x^3}{2x^2 + x^4} = \lim_{x \rightarrow 0} \frac{3x^3}{x^2(2 + x^2)} = \lim_{x \rightarrow 0} \frac{3x}{2 + x^2} = \frac{0}{2} = \boxed{0}.$$

Since we did not obtain the same answer for all five parts, we conclude that

$$\boxed{\lim_{(x,y) \rightarrow (0,0)} \frac{3xy}{2x^2 + y^2} \text{ does not exist.}}$$

26. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x \cdot 0}{x^2 + 3 \cdot 0} = \lim_{x \rightarrow 0} \frac{0}{x^2} = \lim_{x \rightarrow 0} 0 = \boxed{0}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2 \cdot 0 \cdot y}{0 + 3y^2} = \lim_{y \rightarrow 0} \frac{0}{3y^2} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x \cdot x}{x^2 + 3x^2} = \lim_{x \rightarrow 0} \frac{2x^2}{4x^2} = \lim_{x \rightarrow 0} \frac{1}{2} = \boxed{\frac{1}{2}}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x \cdot (3x)}{x^2 + 3(3x)^2} = \lim_{x \rightarrow 0} \frac{6x^2}{x^2 + 27x^2} = \lim_{x \rightarrow 0} \frac{6x^2}{28x^2} = \lim_{x \rightarrow 0} \frac{3}{14} = \boxed{\frac{3}{14}}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x \cdot x^2}{x^2 + 3(x^2)^2} = \lim_{x \rightarrow 0} \frac{2x^3}{x^2 + 3x^4} = \lim_{x \rightarrow 0} \frac{2x^3}{x^2(1 + 3x^2)} = \lim_{x \rightarrow 0} \frac{2x}{1 + 3x^2} = \frac{0}{1} = \boxed{0}.$$

Since we did not obtain the same answer for all five parts,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2xy}{x^2 + 3y^2} \text{ does not exist.}$$

27. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x \cdot 0}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{0}{x^2} = \lim_{x \rightarrow 0} 0 = \boxed{0}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{0 \cdot y^2}{0 + y^3} = \lim_{y \rightarrow 0} \frac{0}{y^3} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x \cdot x^2}{x^2 + x^3} = \lim_{x \rightarrow 0} \frac{x^3}{x^2(1 + x)} = \lim_{x \rightarrow 0} \frac{x}{1 + x} = \frac{0}{1} = \boxed{0}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x \cdot (3x)^2}{x^2 + (3x)^3} = \lim_{x \rightarrow 0} \frac{9x^3}{x^2 + 27x^3} = \lim_{x \rightarrow 0} \frac{9x^3}{x^2(1 + 27x)} = \lim_{x \rightarrow 0} \frac{9x}{(1 + 27x)} = \frac{0}{1} = \boxed{0}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x \cdot (x^2)^2}{x^2 + 3(x^2)^3} = \lim_{x \rightarrow 0} \frac{x^5}{x^2 + 3x^6} = \lim_{x \rightarrow 0} \frac{x^5}{x^2(1 + 3x^4)} = \lim_{x \rightarrow 0} \frac{x^3}{1 + 3x^4} = \frac{0}{1} = \boxed{0}.$$

Although we obtained the same answer for all five parts,

$$\text{no conclusion can be reached about } \lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2 + y^3}.$$

28. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2 \cdot 0}{3x^3 + 0} = \lim_{x \rightarrow 0} \frac{0}{3x^3} = \lim_{x \rightarrow 0} 0 = \boxed{0}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2 \cdot 0 \cdot y}{0 + y^2} = \lim_{y \rightarrow 0} \frac{0}{y^2} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2 \cdot x}{3x^3 + x^2} = \lim_{x \rightarrow 0} \frac{2x^3}{x^2(3x + 1)} = \lim_{x \rightarrow 0} \frac{2x}{3x + 1} = \frac{0}{1} = \boxed{0}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2 \cdot (3x)}{3x^3 + (3x)^2} = \lim_{x \rightarrow 0} \frac{6x^3}{3x^3 + 9x^2} = \lim_{x \rightarrow 0} \frac{6x^3}{x^2(3x + 9)} = \lim_{x \rightarrow 0} \frac{6x}{(3x + 9)} = \frac{0}{9} = \boxed{0}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2 \cdot (x^2)}{3x^3 + (x^2)^2} = \lim_{x \rightarrow 0} \frac{2x^4}{3x^3 + x^4} = \lim_{x \rightarrow 0} \frac{2x^4}{x^3(3 + x)} = \lim_{x \rightarrow 0} \frac{2x}{3 + x} = \frac{0}{3} = \boxed{0}.$$

Although we obtained the same answer for all five parts,

no conclusion can be reached about $\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2y}{3x^3 + y^2}.$

29. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x^2 \cdot 0}{x^4 + 0} = \lim_{x \rightarrow 0} \frac{0}{x^4} = \lim_{x \rightarrow 0} 0 = \boxed{0}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3 \cdot 0 \cdot y^2}{0 + y^4} = \lim_{y \rightarrow 0} \frac{0}{y^4} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x^2 \cdot x^2}{x^4 + x^4} = \lim_{x \rightarrow 0} \frac{3x^4}{2x^4} = \lim_{x \rightarrow 0} \frac{3}{2} = \boxed{\frac{3}{2}}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x^2 \cdot (3x)^2}{x^4 + (3x)^4} = \lim_{x \rightarrow 0} \frac{27x^4}{x^4 + 81x^4} = \lim_{x \rightarrow 0} \frac{27x^4}{82x^4} = \lim_{x \rightarrow 0} \frac{27}{82} = \boxed{\frac{27}{82}}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3x^2 \cdot (x^2)^2}{x^4 + (x^2)^4} = \lim_{x \rightarrow 0} \frac{3x^6}{x^4 + x^8} = \lim_{x \rightarrow 0} \frac{3x^6}{x^4(1 + x^4)} = \lim_{x \rightarrow 0} \frac{3x^2}{1 + x^4} = \frac{0}{1} = \boxed{0}.$$

Since we did not obtain the same answer for all five parts,

$\lim_{(x,y) \rightarrow (0,0)} \frac{3x^2y^2}{x^4 + y^4}$ does not exist.

30. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{x^2}{x^2} = \lim_{x \rightarrow 0} 1 = \boxed{1}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{0}{0 + y^2} = \lim_{y \rightarrow 0} \frac{0}{y^2} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{x^2 + x^2} = \lim_{x \rightarrow 0} \frac{x^2}{2x^2} = \lim_{x \rightarrow 0} \frac{1}{2} = \boxed{\frac{1}{2}}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{x^2 + (3x)^2} = \lim_{x \rightarrow 0} \frac{x^2}{x^2 + 9x^2} = \lim_{x \rightarrow 0} \frac{x^2}{10x^2} = \lim_{x \rightarrow 0} \frac{1}{10} = \boxed{\frac{1}{10}}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{x^2 + (x^2)^2} = \lim_{x \rightarrow 0} \frac{x^2}{x^2 + x^4} = \lim_{x \rightarrow 0} \frac{x^2}{x^2(1 + x^2)} = \lim_{x \rightarrow 0} \frac{1}{1 + x^2} = \frac{1}{1} = \boxed{1}.$$

Since we did not obtain the same answer for all five parts,

$$\boxed{\lim_{(x,y) \rightarrow (0,0)} \frac{x^2}{x^2 + y^2} \text{ does not exist.}}$$

31. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + x \cdot 0}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{x^2}{x^2} = \lim_{x \rightarrow 0} 1 = \boxed{1}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{0 + 0 \cdot y}{0 + y^2} = \lim_{y \rightarrow 0} \frac{0}{y^2} = \lim_{y \rightarrow 0} 0 = \boxed{0}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + x \cdot x}{x^2 + x^2} = \lim_{x \rightarrow 0} \frac{2x^2}{2x^2} = \lim_{x \rightarrow 0} \frac{2}{2} = \boxed{1}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + x \cdot (3x)}{x^2 + (3x)^2} = \lim_{x \rightarrow 0} \frac{x^2 + 3x^2}{x^2 + 9x^2} = \lim_{x \rightarrow 0} \frac{4x^2}{10x^2} = \lim_{x \rightarrow 0} \frac{4}{10} = \boxed{\frac{2}{5}}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + x \cdot x^2}{x^2 + (x^2)^2} = \lim_{x \rightarrow 0} \frac{x^2 + x^3}{x^2 + x^4} = \lim_{x \rightarrow 0} \frac{x^2(1 + x)}{x^2(1 + x^2)} = \lim_{x \rightarrow 0} \frac{1 + x}{1 + x^2} = \frac{1}{1} = \boxed{1}.$$

Since we did not obtain the same answer for all five parts,

$$\boxed{\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + xy}{x^2 + y^2} \text{ does not exist.}}$$

32. (a) Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{(x-0)^2}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{x^2}{x^2} = \lim_{x \rightarrow 0} 1 = \boxed{1}.$$

(b) Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{(0-y)^2}{0+y^2} = \lim_{y \rightarrow 0} \frac{y^2}{y^2} = \lim_{y \rightarrow 0} 1 = \boxed{1}.$$

(c) Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{(x-x)^2}{x^2+x^2} = \lim_{x \rightarrow 0} \frac{0}{2x^2} = \lim_{x \rightarrow 0} 0 = \boxed{0}.$$

(d) Using $y = 3x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{(x-3x)^2}{x^2+(3x)^2} = \lim_{x \rightarrow 0} \frac{(-2x)^2}{x^2+9x^2} = \lim_{x \rightarrow 0} \frac{4x^2}{10x^2} = \lim_{x \rightarrow 0} \frac{4}{10} = \boxed{\frac{2}{5}}.$$

(e) Using $y = x^2$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{(x-x^2)^2}{x^2+(x^2)^2} = \lim_{x \rightarrow 0} \frac{x^2-2x^3+x^4}{x^2+x^4} = \lim_{x \rightarrow 0} \frac{x^2(1-2x+x^2)}{x^2(1+x^2)} = \lim_{x \rightarrow 0} \frac{1-2x+x^2}{1+x^2} = \frac{1}{1} = \boxed{1}.$$

Since we did not obtain the same answer for all five parts,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{(x-y)^2}{x^2+y^2} \text{ does not exist.}$$

33. We investigate the limit using two curves that contain (0,0): the x -axis ($y = 0$) and the y -axis ($x = 0$).
Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2+0}{x^2+0} = \lim_{x \rightarrow 0} \frac{2x^2}{x^2} = \lim_{x \rightarrow 0} 2 = 2.$$

Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2 \cdot 0 + y^2}{0 + y^2} = \lim_{y \rightarrow 0} \frac{y^2}{y^2} = \lim_{y \rightarrow 0} 1 = 1.$$

Since two different answers are obtained, the limit does not exist.

34. We investigate the limit using two curves that contain (0,0): the x -axis ($y = 0$) and the line $y = x$.
Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x \cdot 0}{x^2+0} = \lim_{x \rightarrow 0} \frac{0}{x^2} = \lim_{x \rightarrow 0} 0 = 0.$$

Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x \cdot x}{x^2+x^2} = \lim_{x \rightarrow 0} \frac{2x^2}{2x^2} = \lim_{x \rightarrow 0} 1 = 1.$$

Since two different answers are obtained, the limit does not exist.

35. We investigate the limit using two curves that contain (0,0): the x -axis ($y = 0$) and the y -axis ($x = 0$).
Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^4-0}{x^2+0} = \lim_{x \rightarrow 0} \frac{x^4}{x^2} = \lim_{x \rightarrow 0} x^2 = 0.$$

Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{0-y^2}{0+y^2} = \lim_{y \rightarrow 0} \frac{-y^2}{y^2} = \lim_{y \rightarrow 0} -1 = -1.$$

Since two different answers are obtained, the limit does not exist.

36. We investigate the limit using two curves that contain (0,0): the x -axis ($y = 0$) and the y -axis ($x = 0$). Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + 0}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{x^2}{x^2} = \lim_{x \rightarrow 0} 1 = 1.$$

Using $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{0 + y^4}{0 + y^2} = \lim_{y \rightarrow 0} \frac{y^4}{y^2} = \lim_{y \rightarrow 0} y^2 = 0.$$

Since two different answers are obtained, the limit does not exist.

37. Since f is a polynomial in x and y , it is continuous for all points (x, y) in the plane.
38. Since f is a polynomial in x and y , it is continuous for all points (x, y) in the plane.
39. $f(x, y)$ is a rational function and is therefore continuous on its domain, which is all points (x, y) in the plane at which the denominator is not 0. We see that $x - y = 0$ on the line $y = x$, so this function is continuous at all points (x, y) in the plane except those on the line $y = x$.
40. $f(x, y)$ is a rational function and is therefore continuous on its domain, which is all points (x, y) in the plane at which the denominator is not 0. We see that $1 - xy = 0$ on the hyperbola $xy = 1$, or $y = \frac{1}{x}$, so this function is continuous at all points (x, y) in the plane except those on the hyperbola $y = \frac{1}{x}$.
41. $f(x, y)$ is the composition of two continuous functions, $h(t) = e^t$ and $g(x, y) = x^2 - y^2$, and is therefore continuous itself, for all points (x, y) in the plane.
42. $f(x, y)$ is the composition of the functions $h(t) = \ln t$ and $g(x, y) = x^2 + y^2$. We see that h is continuous on its domain, which is all positive real numbers t . Therefore, f will be continuous on all points (x, y) in the plane such that $x^2 + y^2 > 0$. Since $x^2 + y^2 \geq 0$ for all x, y , we only need eliminate the case $x^2 + y^2 = 0$, which only happens when $(x, y) = (0, 0)$. Therefore, this function is continuous at all points (x, y) in the plane except the point $(0, 0)$.
43. $f(x, y)$ is the composition of two continuous functions, $h(t) = \sin t$ and $g(x, y) = x^2 - y$, and is therefore continuous itself, for all points (x, y) in the plane.
44. $f(x, y)$ is the composition of the functions $h(t) = \cos t$ and $g(x, y) = \sqrt{x^2 - y}$. We see that h is continuous on all real numbers, but g is only continuous on its domain, which is all points (x, y) in the plane except those which will produce a negative quantity under the square root. Therefore, f will be continuous at all points (x, y) in the plane such that $x^2 - y \geq 0$, or such that $y \leq x^2$. Therefore, this function is continuous on all points (x, y) in the plane that satisfy $y \leq x^2$.
45. $f(x, y)$ is the product of two functions. The first the composition of two continuous functions, $k(t) = \sin t$ and $l(x, y) = x + y$, and so is continuous on the entire xy -plane. The second is also the composition of two continuous functions, $k(t) = \cos t$ and $l(x, y) = x - y$, and so is also continuous itself. The product of two continuous functions is continuous, and so f is continuous on all points (x, y) in the plane.
46. $f(x, y)$ is the product of two functions. The first is the function $h(x, y) = h(x) = e^x$, which is continuous on the entire xy -plane. The second is the composition of two continuous functions, $k(t) = \sin t$ and $l(x, y) = xy$, and so is also itself continuous. The product of two continuous functions is continuous, and so f is continuous on all points (x, y) in the plane.

47. $f(x, y)$ is the quotient of two functions. So, we just need to check continuity of both numerator and denominator, as well as find the zeros of the denominator. The numerator is a polynomial so it is continuous on the entire plane. The denominator is an exponential, so it is never equal to 0. We lastly check where the denominator itself is continuous. It is the composition of two continuous functions, $h(t) = e^t$ and $g(x, y) = x^2 - y^2$, and is therefore continuous on the entire xy -plane. Also, note that $e^{x^2-y^2}$ will never be equal to 0. So, f is continuous for all points (x, y) in the plane.

48. $f(x, y)$ is the quotient of two functions. So, we just need to check continuity of both numerator and denominator, as well as find the zeros of the denominator. The numerator is a polynomial so it is continuous on the entire plane. The denominator is the composition of two continuous functions, $h(t) = \ln t$ and $g(x, y) = x^2 + y^2$. We see that h is continuous on its domain, which is all positive real numbers t . Therefore, h will be continuous on all points (x, y) in the plane such that $x^2 + y^2 > 0$. Since $x^2 + y^2 \geq 0$ for all x, y , we only need eliminate the case $x^2 + y^2 = 0$, which only happens when $(x, y) = (0, 0)$. Therefore, the denominator is continuous on all points (x, y) in the plane except the point $(0, 0)$. We still need to determine where the denominator is 0. This will happen when $\ln(x^2 + y^2) = 0$, which occurs when $x^2 + y^2 = 1$. We must eliminate these points. So, f is continuous on all points (x, y) in the plane except $(0, 0)$ and those on the circle $x^2 + y^2 = 1$.

49. Since the function is continuous at $(1, 0)$, we may evaluate it at $(1, 0)$ to find the limit:

$$\lim_{(x,y) \rightarrow (1,0)} \frac{x^2 - y^2}{x - y} = \frac{1 - 0}{1 - 0} = \boxed{1}.$$

50. Since the function is continuous at $(0, 0)$, we may evaluate it at $(0, 0)$ to find the limit:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2y + xy^2}{1 - xy} = \frac{0 + 0}{1 - 0} = \boxed{0}.$$

51. Since the function is continuous at $(1, 1)$, we may evaluate it at $(1, 1)$ to find the limit:

$$\lim_{(x,y) \rightarrow (1,1)} e^{x^2-y^2} = e^{1-1} = e^0 = \boxed{1}.$$

52. Since the function is continuous at $(0, e)$, we may evaluate it at $(0, e)$ to find the limit:

$$\lim_{(x,y) \rightarrow (0,e)} \ln(x^2 + y^2) = \ln(0 + e^2) = \ln(e^2) = \boxed{2}.$$

53. Since the function is continuous at $(\pi/2, \pi)$, we may evaluate it at $(\pi/2, \pi)$ to find the limit:

$$\lim_{(x,y) \rightarrow (\pi/2, \pi)} [\sin(x + y) \cos(x - y)] = \sin\left(\frac{\pi}{2} + \pi\right) \cos\left(\frac{\pi}{2} - \pi\right) = \sin\frac{3\pi}{2} \cos\left(-\frac{\pi}{2}\right) = (-1)(0) = \boxed{0}.$$

54. Since the function is continuous at $(0, \pi/2)$, we may evaluate it at $(0, \pi/2)$ to find the limit:

$$\lim_{(x,y) \rightarrow (0, \pi/2)} e^x \sin(xy) = e^0 \sin\left(0 \cdot \frac{\pi}{2}\right) = 1 \sin 0 = (1)(0) = \boxed{0}.$$

55. Since the function is continuous at $(\pi, 0)$, we may evaluate it at $(\pi, 0)$ to find the limit:

$$\lim_{(x,y) \rightarrow (\pi, 0)} \frac{e^{x^2+y^2} \cos x^2}{\cos y^2} = \frac{e^{\pi^2+0} \cos \pi^2}{\cos 0} = \frac{e^{\pi^2} \cos \pi^2}{1} = \boxed{e^{\pi^2} \cos \pi^2}.$$

56. Since the function is continuous at $(\frac{\pi}{2}, 4)$, we may evaluate it at $(\frac{\pi}{2}, 4)$ to find the limit:

$$\lim_{(x,y) \rightarrow (\pi/2, 4)} \frac{e^{x^2 y}}{\cos(2x)} = \frac{e^{(\frac{\pi}{2})^2 \cdot 4}}{\cos(2 \cdot \frac{\pi}{2})} = \frac{e^{\frac{\pi^2}{4} \cdot 4}}{\cos \pi} = \frac{e^{\pi^2}}{-1} = \boxed{-e^{\pi^2}}.$$

57. Since the function is continuous at $(0, 0)$, we may evaluate it at $(0, 0)$ to find the limit:

$$\lim_{(x,y) \rightarrow (0,0)} \tan^{-1} \left(\frac{e^{x+y}}{y^2 + 1} \right) = \tan^{-1} \left(\frac{e^{0+0}}{0+1} \right) = \tan^{-1} \left(\frac{1}{1} \right) = \tan^{-1}(1) = \boxed{\frac{\pi}{4}}.$$

58. Since the function is continuous at $(\pi, 0)$, we may evaluate it at $(\pi, 0)$ to find the limit:

$$\lim_{(x,y) \rightarrow (\pi,0)} \tan^{-1} [\cos(x+y)] = \tan^{-1} [\cos(\pi+0)] = \tan^{-1}(\cos \pi) = \tan^{-1}(-1) = \boxed{-\frac{\pi}{4}}.$$

Applications and Extensions

59. Note that $(x, y, z) \rightarrow (0, 0, 0)$ corresponds to $t \rightarrow 0$. We replace x, y , and z with their respective expressions in t in the limit:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,0,0)} \frac{2yz}{x^4 + y^2 + z^2} &= \lim_{t \rightarrow 0} \frac{2(t)(t)}{t^4 + t^2 + t^2} = \lim_{t \rightarrow 0} \frac{2t^2}{t^4 + 2t^2} = \lim_{t \rightarrow 0} \frac{2t^2}{t^2(t^2 + 2)} \\ &= \lim_{t \rightarrow 0} \frac{2}{t^2 + 2} = \frac{2}{2} = \boxed{1} \end{aligned}$$

60. Note that $(x, y, z) \rightarrow (0, 0, 0)$ corresponds to $t \rightarrow 0$. We replace x, y , and z with their respective expressions in t in the limit:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,0,0)} \frac{2yz}{x^4 + y^2 + z^2} &= \lim_{t \rightarrow 0} \frac{2(3t)(4t)}{(2t)^4 + (3t)^2 + (4t)^2} = \lim_{t \rightarrow 0} \frac{24t^2}{16t^4 + 25t^2} \\ &= \lim_{t \rightarrow 0} \frac{24t^2}{t^2(16t^2 + 25)} = \lim_{t \rightarrow 0} \frac{24}{16t^2 + 25} = \boxed{\frac{24}{25}} \end{aligned}$$

61. Note that $(x, y, z) \rightarrow (0, 0, 0)$ corresponds to $t \rightarrow 0$. We replace x, y , and z with their respective expressions in t in the limit:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,0,0)} \frac{2yz}{x^4 + y^2 + z^2} &= \lim_{t \rightarrow 0} \frac{2(t^2)(t^2)}{t^4 + (t^2)^2 + (t^2)^2} = \lim_{t \rightarrow 0} \frac{2t^4}{t^4 + t^4 + t^4} = \lim_{t \rightarrow 0} \frac{2t^4}{3t^4} \\ &= \lim_{t \rightarrow 0} \frac{2}{3} = \boxed{\frac{2}{3}} \end{aligned}$$

62. Note that $(x, y, z) \rightarrow (0, 0, 0)$ corresponds to $t \rightarrow 0$. We may then replace x, y , and z with their respective expressions in t to find the limit:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,0,0)} \frac{2yz}{x^4 + y^2 + z^2} &= \lim_{t \rightarrow 0} \frac{2(bt)(ct)}{(at)^4 + (bt)^2 + (ct)^2} = \lim_{t \rightarrow 0} \frac{2bct^2}{a^4t^4 + b^2t^2 + c^2t^2} \\ &= \lim_{t \rightarrow 0} \frac{2bct^2}{t^2(a^4t^2 + b^2 + c^2)} = \lim_{t \rightarrow 0} \frac{2bc}{a^4t^2 + b^2 + c^2} = \frac{2bc}{b^2 + c^2} \end{aligned}$$

This limit is valid as long as $b^2 + c^2 > 0$.

63. Given a number $\varepsilon > 0$, we seek a number $\delta > 0$, so that

$$\text{whenever } 0 < \sqrt{(x-0)^2 + (y-0)^2} < \delta \text{ then } \left| \frac{x^2 y}{x^2 + y^2} - 0 \right| < \varepsilon.$$

That is,

$$\text{whenever } 0 < \sqrt{x^2 + y^2} < \delta \text{ then } \left| \frac{x^2 y}{x^2 + y^2} \right| < \varepsilon.$$

We need to find a connection between $\frac{x^2 y}{x^2 + y^2}$ and $\sqrt{x^2 + y^2}$. We begin with the observation that since $y^2 \geq 0$,

$$x^2 \leq x^2 + y^2.$$

For all points (x, y) not equal to $(0, 0)$, the quantity $x^2 + y^2$ is greater than zero, so we can divide both sides of the inequality by $x^2 + y^2$. We obtain

$$\frac{x^2}{x^2 + y^2} \leq 1.$$

Now,

$$\left| \frac{x^2 y}{x^2 + y^2} \right| = \frac{x^2 |y|}{x^2 + y^2} = |y| \cdot \frac{x^2}{x^2 + y^2} \leq |y| \cdot 1 = \sqrt{y^2} \leq \sqrt{x^2 + y^2}$$

Given $\varepsilon > 0$, we choose $\delta \leq \varepsilon$. Then, whenever $0 < \sqrt{x^2 + y^2} < \delta$, we have

$$\left| \frac{x^2 y}{x^2 + y^2} \right| \leq \sqrt{x^2 + y^2} < \delta \leq \varepsilon.$$

That is,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 y}{x^2 + y^2} = 0.$$

64. Given a number $\varepsilon > 0$, we seek a number $\delta > 0$, so that

$$\text{whenever } 0 < \sqrt{(x-0)^2 + (y-0)^2} < \delta \text{ then } \left| \frac{\sin(x^2 + y^2)}{x^2 + y^2} - 1 \right| < \varepsilon.$$

That is,

$$\text{whenever } 0 < \sqrt{x^2 + y^2} < \delta \text{ then } \left| \frac{\sin(x^2 + y^2)}{x^2 + y^2} - 1 \right| < \varepsilon.$$

We need to find a connection between $\frac{\sin(x^2 + y^2)}{x^2 + y^2} - 1$ and $\sqrt{x^2 + y^2}$. We begin by recalling the following limit:

$$\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1,$$

which we know from Section 1.4, page 108. Using the ε - δ definition of a limit, it follows that given $\varepsilon > 0$, we can choose $\delta_0 > 0$ such that

$$\text{whenever } 0 < \theta < \delta_0 \text{ we have } \left| \frac{\sin \theta}{\theta} - 1 \right| < \varepsilon.$$

Making the substitution $\theta = x^2 + y^2$, we see that

$$\text{whenever } 0 < x^2 + y^2 < \delta_0 \text{ we have } \left| \frac{\sin(x^2 + y^2)}{x^2 + y^2} - 1 \right| < \varepsilon.$$

But, we also see that the inequality $0 < x^2 + y^2 < \delta_0$ is equivalent to $0 < \sqrt{x^2 + y^2} < \sqrt{\delta_0}$. Therefore, given $\varepsilon > 0$, we choose $\delta = \sqrt{\delta_0} > 0$. Then, whenever $0 < \sqrt{x^2 + y^2} < \delta$, we have $0 < x^2 + y^2 < \delta^2 = \delta_0$, and it follows that

$$\left| \frac{\sin(x^2 + y^2)}{x^2 + y^2} - 1 \right| < \varepsilon.$$

That is,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{\sin(x^2 + y^2)}{x^2 + y^2} = 1.$$

65. (a) f is not continuous at $(0,0)$ since this point gives 0 in the denominator.
 (b) We need to determine whether or not the following limit exists:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2 + y^2}.$$

We will use the ε - δ definition of a limit to prove that

$$\lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2 + y^2} = 0.$$

Given a number $\varepsilon > 0$, we seek a number $\delta > 0$, so that

$$\text{whenever } 0 < \sqrt{(x-0)^2 + (y-0)^2} < \delta \text{ then } \left| \frac{xy^2}{x^2 + y^2} - 0 \right| < \varepsilon.$$

That is,

$$\text{whenever } 0 < \sqrt{x^2 + y^2} < \delta \text{ then } \left| \frac{xy^2}{x^2 + y^2} \right| < \varepsilon.$$

We need to find a connection between $\frac{xy^2}{x^2 + y^2}$ and $\sqrt{x^2 + y^2}$. We begin with the observation that since $x^2 \geq 0$,

$$y^2 \leq x^2 + y^2.$$

For all points (x, y) not equal to $(0, 0)$, the quantity $x^2 + y^2$ is greater than zero, so we can divide both sides of the inequality by $x^2 + y^2$. We obtain

$$\frac{y^2}{x^2 + y^2} \leq 1.$$

Now,

$$\left| \frac{xy^2}{x^2 + y^2} \right| = \frac{|x|y^2}{x^2 + y^2} = |x| \cdot \frac{y^2}{x^2 + y^2} \leq |x| \cdot 1 = \sqrt{x^2} \leq \sqrt{x^2 + y^2}$$

Given $\varepsilon > 0$, we choose $\delta \leq \varepsilon$. Then, whenever $0 < \sqrt{x^2 + y^2} < \delta$, we have

$$\left| \frac{xy^2}{x^2 + y^2} \right| \leq \sqrt{x^2 + y^2} < \delta \leq \varepsilon.$$

That is,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2 + y^2} = 0.$$

Because this limit exists, we conclude that yes, it is possible to define $f(0, 0)$ so that f would be continuous at $(0, 0)$.

- (c) Since $\lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2+y^2} = 0$, we define $f(0,0) = 0$ to have $\lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2+y^2} = f(0,0)$, making f continuous at $(0,0)$.

66. (a) f is not continuous at $(0,0)$ since this point gives 0 in the denominator.
 (b) We need to determine whether or not the following limit exists:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2y}{x^2+y^2}.$$

We have already done this in problem 63, but we review the steps here. We will use the ε - δ definition of a limit to prove that

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2y}{x^2+y^2} = 0.$$

Given a number $\varepsilon > 0$, we seek a number $\delta > 0$, so that

$$\text{whenever } 0 < \sqrt{(x-0)^2 + (y-0)^2} < \delta \text{ then } \left| \frac{x^2y}{x^2+y^2} - 0 \right| < \varepsilon.$$

That is,

$$\text{whenever } 0 < \sqrt{x^2 + y^2} < \delta \text{ then } \left| \frac{x^2y}{x^2+y^2} \right| < \varepsilon.$$

We need to find a connection between $\frac{x^2y}{x^2+y^2}$ and $\sqrt{x^2+y^2}$. We begin with the observation that since $y^2 \geq 0$,

$$x^2 \leq x^2 + y^2.$$

For all points (x, y) not equal to $(0, 0)$, the quantity $x^2 + y^2$ is greater than zero, so we can divide both sides of the inequality by $x^2 + y^2$. We obtain

$$\frac{x^2}{x^2 + y^2} \leq 1.$$

Now,

$$\left| \frac{x^2y}{x^2+y^2} \right| = \frac{x^2|y|}{x^2+y^2} = |y| \cdot \frac{x^2}{x^2+y^2} \leq |y| \cdot 1 = \sqrt{y^2} \leq \sqrt{x^2+y^2}$$

Given $\varepsilon > 0$, we choose $\delta \leq \varepsilon$. Then, whenever $0 < \sqrt{x^2+y^2} < \delta$, we have

$$\left| \frac{x^2y}{x^2+y^2} \right| \leq \sqrt{x^2+y^2} < \delta \leq \varepsilon.$$

That is,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2y}{x^2+y^2} = 0.$$

Because this limit exists, we conclude that yes, it is possible to define $f(0,0)$ so that f would be continuous at $(0,0)$.

- (c) Since $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2y}{x^2+y^2} = 0$, we define $f(0,0) = 0$ to have $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2y}{x^2+y^2} = f(0,0)$, making f continuous at $(0,0)$.

67. (a) f is not continuous at $(0,0)$ since this point gives 0 in the denominator.

- (b) In order for us to be able to define $f(0,0)$ so that f is continuous at $(0,0)$, we need $\lim_{(x,y) \rightarrow (0,0)} f(x,y)$ to exist. We first try the limit along two different curves that contain $(0,0)$ to see if we can show that the limit does *not* exist:

Along $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2 + y^2}{x^2 + y^2} = \lim_{y \rightarrow 0} \frac{2(0^2) + y^2}{0^2 + y^2} = \lim_{y \rightarrow 0} \frac{y^2}{y^2} = \lim_{y \rightarrow 0} 1 = 1$$

Along $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{2x^2 + y^2}{x^2 + y^2} = \lim_{x \rightarrow 0} \frac{2x^2 + 0^2}{x^2 + 0^2} = \lim_{x \rightarrow 0} \frac{2x^2}{x^2} = \lim_{x \rightarrow 0} 2 = 2$$

Since we have differing limits along two different curves containing $(0,0)$, the limit does not exist. Therefore, it is not possible to define $f(0,0)$ so that f is continuous at $(0,0)$.

68. (a) f is not continuous at $(0,0)$ since this point gives 0 in the denominator.
 (b) In order for us to be able to define $f(0,0)$ so that f is continuous at $(0,0)$, we need $\lim_{(x,y) \rightarrow (0,0)} f(x,y)$ to exist. We first try the limit along two different curves that contain $(0,0)$ to see if we can show that the limit does *not* exist:

Along $x = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^4 - y^2}{x^2 + y^2} = \lim_{y \rightarrow 0} \frac{0^4 - y^2}{0^2 + y^2} = \lim_{y \rightarrow 0} -\frac{y^2}{y^2} = \lim_{y \rightarrow 0} -1 = -1$$

Along $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^4 - y^2}{x^2 + y^2} = \lim_{x \rightarrow 0} \frac{x^4 - 0^2}{x^2 + 0^2} = \lim_{x \rightarrow 0} \frac{x^4}{x^2} = \lim_{x \rightarrow 0} x^2 = 0$$

Since we have differing limits along two different curves containing $(0,0)$, the limit does not exist. Therefore, it is not possible to define $f(0,0)$ so that f is continuous at $(0,0)$.

69. (a) To determine if f is continuous at $(0,0)$, we must check to see if $\lim_{(x,y) \rightarrow (0,0)} f(x,y) = f(0,0)$. We are given that $f(0,0) = 0$. Therefore, for f to be continuous at $(0,0)$, we would have to have that $\lim_{(x,y) \rightarrow (0,0)} f(x,y) = 0$. This would mean that the limit must be 0 along every curve containing $(0,0)$. But, we see that along the curve given by $y = x$, we have the following (note that since we are *approaching* $(0,0)$ in the following computation and we are not *at* $(0,0)$, we use the expression $\frac{3xy}{x^2 + y^2}$ for f):

$$\lim_{(x,y) \rightarrow (0,0)} \frac{3xy}{x^2 + y^2} = \lim_{x \rightarrow 0} \frac{3x \cdot x}{x^2 + x^2} = \lim_{x \rightarrow 0} \frac{3x^2}{2x^2} = \lim_{x \rightarrow 0} \frac{3}{2} = \frac{3}{2}$$

Since this limit is not 0, the limit of f as (x, y) approaches $(0, 0)$, even if it does exist, cannot be 0, and so this limit, even if it does exist, is not equal to $f(0, 0)$. This means that

f is not continuous at $(0, 0)$.

- (b) In order for us to be able to redefine $f(0, 0)$ so that f is continuous at $(0, 0)$, we need the limit $\lim_{(x, y) \rightarrow (0, 0)} f(x, y)$ to exist. We already know that this limit along the curve $y = x$ is $\frac{3}{2}$. However, we also have the following limit along the curve $x = 0$:

$$\lim_{(x, y) \rightarrow (0, 0)} \frac{3xy}{x^2 + y^2} = \lim_{y \rightarrow 0} \frac{3(0)y}{0^2 + y^2} = \lim_{y \rightarrow 0} \frac{0}{y^2} = \lim_{x \rightarrow 0} 0 = 0$$

This is not equal to the limit along $y = x$, so the limit of $f(x, y)$ as (x, y) approaches $(0, 0)$ does not exist. Therefore, it is not possible to redefine $f(0, 0)$ so that f is continuous at $(0, 0)$.

70. (a) To determine if f is continuous at $(0, 0)$, we must check to see if $\lim_{(x, y) \rightarrow (0, 0)} f(x, y) = f(0, 0)$. We are given that $f(0, 0) = 1$. Therefore, for f to be continuous at $(0, 0)$, we would have to have that $\lim_{(x, y) \rightarrow (0, 0)} f(x, y) = 1$. This would mean that the limit must be 1 along every curve containing $(0, 0)$. But, we see that along the curve given by $x = 0$, we have the following (note that since we are *approaching* $(0, 0)$ in the following computation and we are not *at* $(0, 0)$, we use the expression $\frac{\sin(xy)}{x^2 + y^2}$ for f):

$$\lim_{(x, y) \rightarrow (0, 0)} \frac{\sin(xy)}{x^2 + y^2} = \lim_{y \rightarrow 0} \frac{\sin((0)y)}{0^2 + y^2} = \lim_{y \rightarrow 0} \frac{\sin 0}{y^2} = \lim_{y \rightarrow 0} \frac{0}{y^2} = \lim_{x \rightarrow 0} 0 = 0$$

Since this limit is not 1, the limit of f as (x, y) approaches $(0, 0)$, even if it does exist, cannot be 1, and so this limit, even if it does exist, is not equal to $f(0, 0)$. This means that

f is not continuous at $(0, 0)$.

- (b) In order for us to be able to redefine $f(0, 0)$ so that f is continuous at $(0, 0)$, we need the limit $\lim_{(x, y) \rightarrow (0, 0)} f(x, y)$ to exist. We already know that this limit along the curve $x = 0$ is 0. However, we also have the following limit along the curve $y = x$:

$$\lim_{(x, y) \rightarrow (0, 0)} \frac{\sin(xy)}{x^2 + y^2} = \lim_{x \rightarrow 0} \frac{\sin(x(x))}{x^2 + x^2} = \lim_{x \rightarrow 0} \frac{\sin(x^2)}{2x^2} = \frac{1}{2} \lim_{x \rightarrow 0} \frac{\sin(x^2)}{x^2} = \frac{1}{2}(1) = \frac{1}{2}$$

This is not equal to the limit along $x = 0$, so the limit of $f(x, y)$ as (x, y) approaches $(0, 0)$ does not exist. Therefore, it is not possible to redefine $f(0, 0)$ so that f is continuous at $(0, 0)$.

71. (a) To determine if f is continuous at $(0, 0)$, we must check to see if $\lim_{(x, y) \rightarrow (0, 0)} f(x, y) = f(0, 0)$.

We are given that $f(0, 0) = 1$. Therefore, for f to be continuous at $(0, 0)$, we must have that $\lim_{(x, y) \rightarrow (0, 0)} f(x, y) = 1$. By Problem 64, we know that this limit is indeed equal to 1. Therefore,

f is continuous at $(0, 0)$.

72. (a) To determine if f is continuous at $(0, 0)$, we must check to see if $\lim_{(x, y) \rightarrow (0, 0)} f(x, y) = f(0, 0)$. We are given that $f(0, 0) = 1$. Therefore, for f to be continuous at $(0, 0)$, we would have to have that $\lim_{(x, y) \rightarrow (0, 0)} f(x, y) = 1$. This would mean that the limit must be 1 along every curve containing

$(0,0)$. But, we see that along the curve given by $x = 0$, we have the following (note that since we are *approaching* $(0,0)$ in the following computation and we are not *at* $(0,0)$, we use the expression $\frac{\sin(x^2 - y^2)}{x^2 + y^2}$ for f):

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{\sin(x^2 - y^2)}{x^2 + y^2} &= \lim_{y \rightarrow 0} \frac{\sin(0^2 - y^2)}{0^2 + y^2} = \lim_{y \rightarrow 0} \frac{\sin(-y^2)}{y^2} = \lim_{y \rightarrow 0} \frac{-\sin(y^2)}{y^2} = - \lim_{y \rightarrow 0} \frac{\sin(y^2)}{y^2} \\ &= -1 \end{aligned}$$

Since this limit is not 1, the limit of f as (x, y) approaches $(0,0)$, even if it does exist, cannot be 1, and it follows that it is not equal to $f(0,0)$. This means that f is not continuous at $(0,0)$.

- (b) In order for us to be able to redefine $f(0,0)$ so that f is continuous at $(0,0)$, we need the limit $\lim_{(x,y) \rightarrow (0,0)} f(x, y)$ to exist. We already know that this limit along the curve $x = 0$ is -1 . However, we also have the following limit along the curve $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{\sin(x^2 - y^2)}{x^2 + y^2} = \lim_{x \rightarrow 0} \frac{\sin(x^2 - 0^2)}{x^2 + 0^2} = \lim_{x \rightarrow 0} \frac{\sin(x^2)}{x^2} = 1$$

This is not equal to the limit along $x = 0$, so the limit of $f(x, y)$ as (x, y) approaches $(0,0)$ does not exist. Therefore, it is not possible to redefine $f(0,0)$ so that f is continuous at $(0,0)$.

Challenge Problems

73. We convert using the formulas $x = r \cos \theta$, $y = r \sin \theta$, and $x^2 + y^2 = r^2$. Also, note that if $(x, y) \rightarrow (0, 0)$, this implies that r^2 also goes to 0, as does r . Also, θ may take any value since sending r to 0 automatically takes us toward the origin, and because the function $\frac{(r \cos \theta)^2 (r \sin \theta)}{r^2}$ is defined for any θ . Therefore, we need consider only the limit as $r \rightarrow 0$.

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{x^2 y}{x^2 + y^2} &= \lim_{(r,\theta) \rightarrow (0,0)} \frac{(r \cos \theta)^2 (r \sin \theta)}{r^2} = \lim_{(r,\theta) \rightarrow (0,0)} \frac{r^3 \cos^2 \theta \sin \theta}{r^2} = \lim_{r \rightarrow 0} r \cos^2 \theta \sin \theta \\ &= 0 \text{ for any value of } \theta. \end{aligned}$$

Therefore, the limit is $\boxed{0}$.

74. We convert using the formulas $x = r \cos \theta$, $y = r \sin \theta$, and $x^2 + y^2 = r^2$. Also, note that if $(x, y) \rightarrow (0, 0)$, this implies that r^2 also goes to 0, as does r . Also, θ may take any value since sending r to 0 automatically takes us toward the origin, and because the function $\frac{(r \cos \theta)(r \sin \theta)^2}{r^2}$ is defined for any θ . Therefore, we need consider only the limit as $r \rightarrow 0$.

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{xy^2}{x^2 + y^2} &= \lim_{r \rightarrow 0} \frac{(r \cos \theta)(r \sin \theta)^2}{r^2} = \lim_{r \rightarrow 0} \frac{r^3 \cos \theta \sin^2 \theta}{r^2} = \lim_{r \rightarrow 0} r \cos \theta \sin^2 \theta \\ &= 0 \text{ for any value of } \theta. \end{aligned}$$

Therefore, the limit is $\boxed{0}$.

75. We convert using the formulas $x = r \cos \theta$, $y = r \sin \theta$, and $x^2 + y^2 = r^2$. Also, note that if $(x, y) \rightarrow (0, 0)$, this implies that r^2 also goes to 0, as does r . Also, θ may take any value since sending r to 0 automatically takes us toward the origin, and because the function $\frac{\cos(r^2)}{r^2}$ is defined for any θ . Therefore, we need consider only the limit as $r \rightarrow 0$.

$$\lim_{(x,y) \rightarrow (0,0)} \frac{\cos(x^2 + y^2)}{x^2 + y^2} = \lim_{r \rightarrow 0} \frac{\cos(r^2)}{r^2}.$$

We see that (whether the value 0 is approached from the left or right) while the numerator goes to 1, the denominator becomes infinitesimally small. This causes the entire quantity to approach ∞ , i.e. the limit does not exist.

76. We convert using the formulas $x = r \cos \theta$, $y = r \sin \theta$, and $x^2 + y^2 = r^2$. Also, note that if $(x, y) \rightarrow (0, 0)$, this implies that r^2 also goes to 0, as does r . Also, θ may take any value since sending r to 0 automatically takes us toward the origin, and because the function $\frac{\sin(r^2)}{r^2}$ is defined for any θ . Therefore, we need consider only the limit as $r \rightarrow 0$.

$$\lim_{(x,y) \rightarrow (0,0)} \frac{\sin(x^2 + y^2)}{x^2 + y^2} = \lim_{r \rightarrow 0} \frac{\sin(r^2)}{r^2} = \boxed{1}.$$

77. Since $x - 2y$ is a factor of the numerator, we can use algebra to solve this problem.

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{x^3 - 4x^2y + 4xy^2 + 5x - 10y}{x - 2y} &= \lim_{(x,y) \rightarrow (0,0)} \frac{x^3 - 2x^2y - 2x^2y + 4xy^2 + 5x - 10y}{x - 2y} \\ &= \lim_{(x,y) \rightarrow (0,0)} \frac{x^2(x - 2y) - 2xy(x - 2y) + 5(x - 2y)}{x - 2y} \\ &= \lim_{(x,y) \rightarrow (0,0)} \frac{(x^2 - 2xy + 5)(x - 2y)}{x - 2y} \\ &= \lim_{(x,y) \rightarrow (0,0)} x^2 - 2xy + 5 \\ &= \lim_{(x,y) \rightarrow (0,0)} x^2 - 2 \cdot \lim_{x \rightarrow 0} x \cdot \lim_{y \rightarrow 0} y + \lim_{(x,y) \rightarrow (0,0)} 5 \\ &= 0 - 2 \cdot 0 \cdot 0 + 5 = \boxed{5} \end{aligned}$$

Chapter 12: Functions of Several Variables

12.3: Partial Derivatives

Concepts and Vocabulary

- False. It is the other way around; to find the partial derivative $f_y(x, y)$, we need to differentiate f with respect to y while treating x as if it were a constant.
- b, $y = y_0$. See the “Slope of a Tangent Line” theorem, on page 831. Alternatively, since calculating $f_x(x, y)$ involves treating y as if it were a constant, $f_x(x_0, y_0)$ should be the slope of the tangent line to a curve located in a plane of the form $y = \text{constant}$.
- True. This is because of the interpretation of $f_x(x, y)$ as a rate of change, as discussed on page 832.
- mixed. The second-order partial derivatives that are computed by taking the derivative with respect to x first, and then with respect to y , or vice versa, are called the mixed partials.

5. False. This can be checked by computing the partial derivatives:

$$f_x(x, y) = \frac{\partial}{\partial x} (x \cos y) = \cos y \frac{\partial}{\partial x} (x) = \cos y \cdot 1 = \cos y;$$

$$f_y(x, y) = \frac{\partial}{\partial y} (x \cos y) = x \frac{\partial}{\partial y} (\cos y) = x(-\sin y) = -x \sin y.$$

The two are not equal.

6. treat the variables x and z as constants, and differentiate f with respect to y . When we compute partial derivatives, all variables, except for the one that we are computing the partial derivative with respect to, are treated as constants. Since $f_y(x, y, z)$ is the partial derivative with respect to y , x and z must be treated as constants.

Skill Building

7.

$$f_x(x, y) = \frac{\partial}{\partial x} (x^2y + 6y^2) = \frac{\partial}{\partial x} (x^2y) + \frac{\partial}{\partial x} (6y^2) = y \frac{\partial}{\partial x} (x^2) + 0 = y \cdot 2x$$

$$\boxed{f_x(x, y) = 2xy}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} (x^2y + 6y^2) = \frac{\partial}{\partial y} (x^2y) + \frac{\partial}{\partial y} (6y^2) \\ &= x^2 \frac{\partial}{\partial y} (y) + 6 \frac{\partial}{\partial y} (y^2) = x^2 \cdot 1 + 6 \cdot 2y = x^2 + 12y \end{aligned}$$

$$\boxed{f_y(x, y) = x^2 + 12y}$$

8.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} (3x^2 + 6xy^3) = \frac{\partial}{\partial x} (3x^2) + \frac{\partial}{\partial x} (6xy^3) \\ &= 3 \frac{\partial}{\partial x} (x^2) + 6y^3 \frac{\partial}{\partial x} (x) = 3 \cdot 2x + 6y^3 \cdot 1 = 6x + 6y^3 \end{aligned}$$

$$\boxed{f_x(x, y) = 6x + 6y^3}$$

$$f_y(x, y) = \frac{\partial}{\partial y} (3x^2 + 6xy^3) = \frac{\partial}{\partial y} (3x^2) + \frac{\partial}{\partial y} (6xy^3) = 0 + 6x \frac{\partial}{\partial y} (y^3) = 6x \cdot 3y^2 = 18xy^2$$

$$\boxed{f_y(x, y) = 18xy^2}$$

9.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} \left(\frac{x-y}{x+y} \right) = \frac{\left(\frac{\partial}{\partial x} (x-y) \right) (x+y) - (x-y) \left(\frac{\partial}{\partial x} (x+y) \right)}{(x+y)^2} \\ &= \frac{(x+y) \cdot 1 - (x-y) \cdot 1}{(x+y)^2} = \frac{2y}{(x+y)^2} \end{aligned}$$

$$f_x(x, y) = \frac{2y}{(x+y)^2}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} \left(\frac{x-y}{x+y} \right) = \frac{\left(\frac{\partial}{\partial y} (x-y) \right) (x+y) - (x-y) \left(\frac{\partial}{\partial y} (x+y) \right)}{(x+y)^2} \\ &= \frac{(x+y) \cdot (-1) - (x-y) \cdot 1}{(x+y)^2} = -\frac{2x}{(x+y)^2} \end{aligned}$$

$$f_y(x, y) = -\frac{2x}{(x+y)^2}$$

10.

$$f_x(x, y) = \frac{\partial}{\partial x} \left(\frac{x+y}{y^2} \right) = \frac{1}{y^2} \frac{\partial}{\partial x} (x+y) = \frac{1}{y^2} \cdot 1 = \frac{1}{y^2}$$

$$f_x(x, y) = \frac{1}{y^2}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} \left(\frac{x+y}{y^2} \right) = \frac{y^2 \left(\frac{\partial}{\partial y} (x+y) \right) - \left(\frac{\partial}{\partial y} (y^2) \right) (x+y)}{(y^2)^2} \\ &= \frac{y^2 \cdot 1 - (2y) \cdot (x+y)}{y^4} = \frac{y^2 - 2xy - 2y^2}{y^4} = \frac{-2xy - y^2}{y^4} = \frac{-y(2x+y)}{y^4} = -\frac{2x+y}{y^3} \end{aligned}$$

$$f_y(x, y) = -\frac{2x+y}{y^3}$$

11.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} (e^y \cos x + e^x \sin y) = \frac{\partial}{\partial x} (e^y \cos x) + \frac{\partial}{\partial x} (e^x \sin y) \\ &= e^y \frac{\partial}{\partial x} (\cos x) + \sin y \frac{\partial}{\partial x} (e^x) = e^y (-\sin x) + \sin y \cdot e^x = -e^y \sin x + e^x \sin y \end{aligned}$$

$$f_x(x, y) = -e^y \sin x + e^x \sin y$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} (e^y \cos x + e^x \sin y) = \frac{\partial}{\partial y} (e^y \cos x) + \frac{\partial}{\partial y} (e^x \sin y) \\ &= \cos x \frac{\partial}{\partial y} (e^y) + e^x \frac{\partial}{\partial y} (\sin y) = \cos x \cdot e^y + e^x \cdot \cos y = e^y \cos x + e^x \cos y \end{aligned}$$

$$f_y(x, y) = e^y \cos x + e^x \cos y$$

12.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} (x^2 \cos y + y^2 \sin x) = \frac{\partial}{\partial x} (x^2 \cos y) + \frac{\partial}{\partial x} (y^2 \sin x) \\ &= \cos y \frac{\partial}{\partial x} (x^2) + y^2 \frac{\partial}{\partial x} (\sin x) = \cos y \cdot 2x + y^2 \cdot \cos x = 2x \cos y + y^2 \cos x \end{aligned}$$

$$\boxed{f_x(x, y) = 2x \cos y + y^2 \cos x}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} (x^2 \cos y + y^2 \sin x) = \frac{\partial}{\partial y} (x^2 \cos y) + \frac{\partial}{\partial y} (y^2 \sin x) \\ &= x^2 \frac{\partial}{\partial y} (\cos y) + \sin x \frac{\partial}{\partial y} (y^2) = x^2 (-\sin y) + \sin x \cdot 2y = -x^2 \sin y + 2y \sin x \end{aligned}$$

$$\boxed{f_y(x, y) = -x^2 \sin y + 2y \sin x}$$

13.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} (x^2 e^{xy}) = \frac{\partial}{\partial x} (x^2) \cdot e^{xy} + x^2 \cdot \frac{\partial}{\partial x} (e^{xy}) \\ &= 2x \cdot e^{xy} + x^2 e^{xy} \cdot \frac{\partial}{\partial x} (xy) = 2x \cdot e^{xy} + x^2 e^{xy} \cdot y = 2x e^{xy} + x^2 y e^{xy} \end{aligned}$$

$$\boxed{f_x(x, y) = 2x e^{xy} + x^2 y e^{xy}}$$

$$f_y(x, y) = \frac{\partial}{\partial y} (x^2 e^{xy}) = x^2 \frac{\partial}{\partial y} (e^{xy}) = x^2 e^{xy} \frac{\partial}{\partial y} (xy) = x^2 e^{xy} \cdot x = x^3 e^{xy}$$

$$\boxed{f_y(x, y) = x^3 e^{xy}}$$

14.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} (\cos(x^2 y^3)) = -\sin(x^2 y^3) \cdot \frac{\partial}{\partial x} (x^2 y^3) \\ &= -\sin(x^2 y^3) \cdot y^3 \cdot \frac{\partial}{\partial x} (x^2) = -\sin(x^2 y^3) \cdot y^3 \cdot 2x = -2xy^3 \sin(x^2 y^3) \end{aligned}$$

$$\boxed{f_x(x, y) = -2xy^3 \sin(x^2 y^3)}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} (\cos(x^2 y^3)) = -\sin(x^2 y^3) \cdot \frac{\partial}{\partial y} (x^2 y^3) \\ &= -\sin(x^2 y^3) \cdot x^2 \cdot \frac{\partial}{\partial y} (y^3) = -\sin(x^2 y^3) \cdot x^2 \cdot 3y^2 = -3x^2 y^2 \sin(x^2 y^3) \end{aligned}$$

$$\boxed{f_y(x, y) = -3x^2 y^2 \sin(x^2 y^3)}$$

15.

$$\begin{aligned} \frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} \left(\tan^{-1} \frac{y}{x} \right) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{\partial}{\partial x} \left(\frac{y}{x} \right) \\ &= \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot y \cdot \frac{\partial}{\partial x} (x^{-1}) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot y \cdot (-x^{-2}) = \frac{x^2}{x^2 + y^2} \cdot \frac{-y}{x^2} = -\frac{y}{x^2 + y^2} \end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = -\frac{y}{x^2 + y^2}}$$

$$\begin{aligned}
\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} \left(\tan^{-1} \frac{y}{x} \right) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{\partial}{\partial y} \left(\frac{y}{x} \right) \\
&= \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{1}{x} \cdot \frac{\partial}{\partial y} (y) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{1}{x} \cdot 1 = \frac{x^2}{x^2 + y^2} \cdot \frac{1}{x} = \frac{x}{x^2 + y^2}
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial y} = \frac{x}{x^2 + y^2}}$$

16.

$$\begin{aligned}
\frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} (\sin^2(2xy)) = 2 \sin(2xy) \cdot \frac{\partial}{\partial x} (\sin(2xy)) = 2 \sin(2xy) \cdot \cos(2xy) \cdot \frac{\partial}{\partial x} (2xy) \\
&= 2 \sin(2xy) \cdot \cos(2xy) \cdot 2y \cdot \frac{\partial}{\partial x} (x) = 2 \sin(2xy) \cdot \cos(2xy) \cdot 2y \cdot 1 = 4y \sin(2xy) \cos(2xy)
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = 4y \sin(2xy) \cos(2xy)}$$

$$\begin{aligned}
\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} (\sin^2(2xy)) = 2 \sin(2xy) \cdot \frac{\partial}{\partial y} (\sin(2xy)) = 2 \sin(2xy) \cdot \cos(2xy) \cdot \frac{\partial}{\partial y} (2xy) \\
&= 2 \sin(2xy) \cdot \cos(2xy) \cdot 2x \cdot \frac{\partial}{\partial y} (y) = 2 \sin(2xy) \cdot \cos(2xy) \cdot 2x \cdot 1 = 4x \sin(2xy) \cos(2xy)
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial y} = 4x \sin(2xy) \cos(2xy)}$$

17.

$$\begin{aligned}
\frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} (\sin(e^{x^2 y})) = \cos(e^{x^2 y}) \cdot \frac{\partial}{\partial x} (e^{x^2 y}) = \cos(e^{x^2 y}) \cdot e^{x^2 y} \cdot \frac{\partial}{\partial x} (x^2 y) \\
&= \cos(e^{x^2 y}) \cdot e^{x^2 y} \cdot y \cdot \frac{\partial}{\partial x} (x^2) = \cos(e^{x^2 y}) \cdot e^{x^2 y} \cdot y \cdot 2x = 2xy e^{x^2 y} \cos(e^{x^2 y})
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = 2xy e^{x^2 y} \cos(e^{x^2 y})}$$

$$\begin{aligned}
\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} (\sin(e^{x^2 y})) = \cos(e^{x^2 y}) \cdot \frac{\partial}{\partial y} (e^{x^2 y}) = \cos(e^{x^2 y}) \cdot e^{x^2 y} \cdot \frac{\partial}{\partial y} (x^2 y) \\
&= \cos(e^{x^2 y}) \cdot e^{x^2 y} \cdot x^2 \cdot \frac{\partial}{\partial y} (y) = \cos(e^{x^2 y}) \cdot e^{x^2 y} \cdot x^2 \cdot 1 = x^2 e^{x^2 y} \cos(e^{x^2 y})
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial y} = x^2 e^{x^2 y} \cos(e^{x^2 y})}$$

18.

$$\begin{aligned}
\frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} (\sin[\ln(x^2 + y^2)]) = \cos[\ln(x^2 + y^2)] \cdot \frac{\partial}{\partial x} (\ln(x^2 + y^2)) \\
&= \cos[\ln(x^2 + y^2)] \cdot \frac{1}{x^2 + y^2} \cdot \frac{\partial}{\partial x} (x^2 + y^2) = \cos[\ln(x^2 + y^2)] \cdot \frac{1}{x^2 + y^2} \cdot (2x + 0) \\
&= \cos[\ln(x^2 + y^2)] \cdot \frac{2x}{x^2 + y^2}
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = \cos[\ln(x^2 + y^2)] \cdot \frac{2x}{x^2 + y^2}}$$

$$\begin{aligned}\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} (\sin[\ln(x^2 + y^2)]) = \cos[\ln(x^2 + y^2)] \cdot \frac{\partial}{\partial y} (\ln(x^2 + y^2)) \\ &= \cos[\ln(x^2 + y^2)] \cdot \frac{1}{x^2 + y^2} \cdot \frac{\partial}{\partial y} (x^2 + y^2) = \cos[\ln(x^2 + y^2)] \cdot \frac{1}{x^2 + y^2} \cdot (0 + 2y) \\ &= \cos[\ln(x^2 + y^2)] \cdot \frac{2y}{x^2 + y^2}\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial y} = \cos[\ln(x^2 + y^2)] \cdot \frac{2y}{x^2 + y^2}}$$

19.

$$\begin{aligned}\frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} (e^{(x^2+y^2)^{1.2}}) = e^{(x^2+y^2)^{1.2}} \cdot \frac{\partial}{\partial x} ((x^2 + y^2)^{1.2}) \\ &= e^{(x^2+y^2)^{1.2}} \cdot 1.2 \cdot (x^2 + y^2)^{0.2} \cdot \frac{\partial}{\partial x} (x^2 + y^2) = e^{(x^2+y^2)^{1.2}} \cdot 1.2 \cdot (x^2 + y^2)^{0.2} \cdot (2x + 0) \\ &= 2.4x(x^2 + y^2)^{0.2} e^{(x^2+y^2)^{1.2}}\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = 2.4x(x^2 + y^2)^{0.2} e^{(x^2+y^2)^{1.2}}}$$

$$\begin{aligned}\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} (e^{(x^2+y^2)^{1.2}}) = e^{(x^2+y^2)^{1.2}} \cdot \frac{\partial}{\partial y} ((x^2 + y^2)^{1.2}) \\ &= e^{(x^2+y^2)^{1.2}} \cdot 1.2 \cdot (x^2 + y^2)^{0.2} \cdot \frac{\partial}{\partial y} (x^2 + y^2) = e^{(x^2+y^2)^{1.2}} \cdot 1.2 \cdot (x^2 + y^2)^{0.2} \cdot (0 + 2y) \\ &= 2.4y(x^2 + y^2)^{0.2} e^{(x^2+y^2)^{1.2}}\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial y} = 2.4y(x^2 + y^2)^{0.2} e^{(x^2+y^2)^{1.2}}}$$

20.

$$\begin{aligned}\frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} (\ln \sqrt{x^2 + y^2}) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial x} (\sqrt{x^2 + y^2}) \\ &= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial x} ((x^2 + y^2)^{1/2}) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot \frac{\partial}{\partial x} (x^2 + y^2) \\ &= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot (2x + 0) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{x^2 + y^2}} \cdot 2x = \frac{x}{x^2 + y^2}\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = \frac{x}{x^2 + y^2}}$$

$$\begin{aligned}
\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} \left(\ln \sqrt{x^2 + y^2} \right) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial y} \left(\sqrt{x^2 + y^2} \right) \\
&= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial y} \left((x^2 + y^2)^{1/2} \right) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \frac{\partial}{\partial y} (x^2 + y^2) \\
&= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot (0 + 2y) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{x^2 + y^2}} \cdot 2y = \frac{y}{x^2 + y^2}
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial y} = \frac{y}{x^2 + y^2}}$$

21. We have the following first- and second-order partial derivatives for the function $f(x, y) = 6x^2 - 8xy + 9y^2$:

$$f_x = 12x - 8y$$

$$f_y = -8x + 18y$$

$$\boxed{f_{xx} = 12}$$

$$\boxed{f_{xy} = -8}$$

$$\boxed{f_{yx} = -8}$$

$$\boxed{f_{yy} = 18}$$

We see that $\boxed{\text{it is indeed the case that } f_{xy} = f_{yx}}$.

22. We have the following first- and second-order partial derivatives for the function $f(x, y) = (2x + 3y)(3x - 2y)$, which we obtain by first expanding our expression for $f(x, y)$ to $f(x, y) = 6x^2 + 5xy - 6y^2$:

$$f_x = 12x + 5y$$

$$f_y = 5x - 12y$$

$$\boxed{f_{xx} = 12}$$

$$\boxed{f_{xy} = 5}$$

$$\boxed{f_{yx} = 5}$$

$$\boxed{f_{yy} = -12}$$

We see that $\boxed{\text{it is indeed the case that } f_{xy} = f_{yx}}$.

23. We have the following first- and second-order partial derivatives for the function $f(x, y) = \ln(x^3 + y^2)$:

$$f_x = \frac{1}{x^3 + y^2} (3x^2) = \frac{3x^2}{x^3 + y^2}$$

$$f_{xx} = \frac{6x(x^3 + y^2) - 3x^2(3x^2)}{(x^3 + y^2)^2} = \frac{-3x^4 + 6xy^2}{(x^3 + y^2)^2} = \frac{-3x(x^3 - 2y^2)}{(x^3 + y^2)^2}$$

$$\boxed{f_{xx} = \frac{-3x(x^3 - 2y^2)}{(x^3 + y^2)^2}}$$

$$f_{xy} = 3x^2[(-1)(x^3 + y^2)^{-2}(2y)] = \frac{-6x^2y}{(x^3 + y^2)^2}$$

$$\boxed{f_{xy} = \frac{-6x^2y}{(x^3 + y^2)^2}}$$

$$f_y = \frac{1}{x^3 + y^2} (2y) = \frac{2y}{x^3 + y^2}$$

$$f_{yx} = 2y[(-1)(x^3 + y^2)^{-2}(3x^2)] = \frac{-6x^2y}{(x^3 + y^2)^2}$$

$$\boxed{f_{yx} = \frac{-6x^2y}{(x^3 + y^2)^2}}$$

$$f_{yy} = \frac{2(x^3 + y^2) - 2y(2y)}{(x^3 + y^2)^2} = \frac{2x^3 - 2y^2}{(x^3 + y^2)^2} = \frac{2(x^3 - y^2)}{(x^3 + y^2)^2}$$

$$\boxed{f_{yy} = \frac{2(x^3 - y^2)}{(x^3 + y^2)^2}}$$

We see that $\boxed{\text{it is indeed the case that } f_{xy} = f_{yx}}.$

24. We have the following first- and second-order partial derivatives for the function $f(x, y) = e^{2x+3y}$:

$$f_x = e^{2x+3y} \cdot 2 = 2e^{2x+3y}$$

$$f_y = e^{2x+3y} \cdot 3 = 3e^{2x+3y}$$

$$f_{xx} = 2e^{2x+3y} \cdot 2 = 4e^{2x+3y}$$

$$f_{yx} = 3e^{2x+3y} \cdot 2 = 6e^{2x+3y}$$

$$\boxed{f_{xx} = 4e^{2x+3y}}$$

$$\boxed{f_{yx} = 6e^{2x+3y}}$$

$$f_{xy} = 2e^{2x+3y} \cdot 3 = 6e^{2x+3y}$$

$$f_{yy} = 3e^{2x+3y} \cdot 3 = 9e^{2x+3y}$$

$$\boxed{f_{xy} = 6e^{2x+3y}}$$

$$\boxed{f_{yy} = 9e^{2x+3y}}$$

We see that $\boxed{\text{it is indeed the case that } f_{xy} = f_{yx}}.$

25. We have the following first- and second-order partial derivatives for the function $f(x, y) = \cos(x^2y^3)$:

$$f_x = -\sin(x^2y^3) \cdot 2xy^3 = -2xy^3 \sin(x^2y^3)$$

$$f_{xx} = (-2xy^3)[\cos(x^2y^3) \cdot 2xy^3] + [-2y^3 \sin(x^2y^3)] = -4x^2y^6 \cos(x^2y^3) - 2y^3 \sin(x^2y^3)$$

$$\boxed{f_{xx} = -4x^2y^6 \cos(x^2y^3) - 2y^3 \sin(x^2y^3)}$$

$$f_{xy} = -2xy^3[\cos(x^2y^3) \cdot x^2(3y^2)] + [-2x(3y^2) \sin(x^2y^3)] = -6x^3y^5 \cos(x^2y^3) - 6xy^2 \sin(x^2y^3)$$

$$\boxed{f_{xy} = -6x^3y^5 \cos(x^2y^3) - 6xy^2 \sin(x^2y^3)}$$

$$f_y = -\sin(x^2y^3) \cdot x^2(3y^2) = -3x^2y^2 \sin(x^2y^3)$$

$$f_{yx} = -3x^2y^2[\cos(x^2y^3) \cdot 2xy^3] + [-6xy^2 \sin(x^2y^3)] = -6x^3y^5 \cos(x^2y^3) - 6xy^2 \sin(x^2y^3)$$

$$\boxed{f_{yx} = -6x^3y^5 \cos(x^2y^3) - 6xy^2 \sin(x^2y^3)}$$

$$f_{yy} = -3x^2y^2[\cos(x^2y^3) \cdot x^2(3y^2)] + [-3x^2(2y)\sin(x^2y^3)] = -9x^4y^4\cos(x^2y^3) - 6x^2y\sin(x^2y^3)$$

$$\boxed{f_{yy} = -9x^4y^4\cos(x^2y^3) - 6x^2y\sin(x^2y^3)}$$

We see that $\boxed{\text{it is indeed the case that } f_{xy} = f_{yx}}$.

26. We have the following first- and second-order partial derivatives for the function $f(x, y) = \sin^2(xy)$:

$$f_x = 2\sin(xy)\cos(xy) \cdot y = 2y\sin(xy)\cos(xy)$$

$$f_{xx} = 2y\sin(xy)[- \sin(xy) \cdot y] + [2y\cos(xy) \cdot y]\cos(xy) = -2y^2\sin^2(xy) + 2y^2\cos^2(xy)$$

$$= 2y^2[\cos^2(xy) - \sin^2(xy)] = 2y^2\cos(2xy)$$

$$\boxed{f_{xx} = 2y^2\cos(2xy)}$$

$$f_{xy} = 2y\sin(xy)[- \sin(xy) \cdot x] + [2y\cos(xy) \cdot x + 2\sin(xy)]\cos(xy)$$

$$= -2xy\sin^2(xy) + 2xy\cos^2(xy) + 2\sin(xy)\cos(xy)$$

$$= 2xy[\cos^2(xy) - \sin^2(xy)] + 2\sin(xy)\cos(xy)$$

$$= 2xy\cos(2xy) + \sin(2xy)$$

$$\boxed{f_{xy} = 2xy\cos(2xy) + \sin(2xy)}$$

$$f_y = 2\sin(xy)\cos(xy) \cdot x = 2x\sin(xy)\cos(xy)$$

$$f_{yx} = 2x\sin(xy)[- \sin(xy) \cdot y] + [2x\cos(xy) \cdot y + 2\sin(xy)]\cos(xy)$$

$$= -2xy\sin^2(xy) + 2xy\cos^2(xy) + 2\sin(xy)\cos(xy)$$

$$= 2xy[\cos^2(xy) - \sin^2(xy)] + 2\sin(xy)\cos(xy)$$

$$= 2xy\cos(2xy) + \sin(2xy)$$

$$\boxed{f_{yx} = 2xy\cos(2xy) + \sin(2xy)}$$

$$f_{yy} = 2x\sin(xy)[- \sin(xy) \cdot x] + [2x\cos(xy) \cdot x]\cos(xy) = -2x^2\sin^2(xy) + 2x^2\cos^2(xy)$$

$$= 2x^2[\cos^2(xy) - \sin^2(xy)] = 2x^2\cos(2xy)$$

$$\boxed{f_{yy} = 2x^2\cos(2xy)}$$

We see that $\boxed{\text{it is indeed the case that } f_{xy} = f_{yx}}$.

27. We have the following first-order partial derivatives for the function $f(x, y, z) = xy + yz + xz$:

$$\boxed{f_x = y + z}$$

$$\boxed{f_y = x + z}$$

$$f_z = y + x = x + y$$

$$\boxed{f_z = x + y}$$

28. We have the following first-order partial derivatives for the function $f(x, y, z) = xe^y + ye^z + ze^x$:

$$\boxed{f_x = e^y + ze^x}$$

$$\boxed{f_y = xe^y + e^z}$$

$$\boxed{f_z = ye^z + e^x}$$

29. We have the following first-order partial derivatives for the function $f(x, y, z) = xy \sin z - yz \sin x$:

$$\boxed{f_x = y \sin z - yz \cos x}$$

$$\boxed{f_y = x \sin z - z \sin x}$$

$$\boxed{f_z = xy \cos z - y \sin x}$$

30. We have the following first-order partial derivatives for the function $f(x, y, z) = \frac{1}{\sqrt{x^2 + y^2 + z^2}}$:

$$f_x = -\frac{1}{2}(x^2 + y^2 + z^2)^{-3/2}(2x) = \frac{-x}{(x^2 + y^2 + z^2)^{3/2}}$$

$$\boxed{f_x = \frac{-x}{(x^2 + y^2 + z^2)^{3/2}}}$$

$$f_y = -\frac{1}{2}(x^2 + y^2 + z^2)^{-3/2}(2y) = \frac{-y}{(x^2 + y^2 + z^2)^{3/2}}$$

$$\boxed{f_y = \frac{-y}{(x^2 + y^2 + z^2)^{3/2}}}$$

$$f_z = -\frac{1}{2}(x^2 + y^2 + z^2)^{-3/2}(2z) = \frac{-z}{(x^2 + y^2 + z^2)^{3/2}}$$

$$\boxed{f_z = \frac{-z}{(x^2 + y^2 + z^2)^{3/2}}}$$

31. We have the following first-order partial derivatives for the function $f(x, y, z) = z \tan^{-1} \left(\frac{y}{x} \right)$:

$$f_x = z \left[\frac{1}{1 + \left(\frac{y}{x} \right)^2} \right] (-yx^{-2}) = \frac{-yz}{x^2 \left[1 + \frac{y^2}{x^2} \right]} = \frac{-yz}{x^2 + y^2}$$

$$\boxed{f_x = \frac{-yz}{x^2 + y^2}}$$

$$f_y = z \left[\frac{1}{1 + \left(\frac{y}{x} \right)^2} \right] \left(\frac{1}{x} \right) = \frac{z}{x \left[1 + \frac{y^2}{x^2} \right]} = \frac{z}{x + \frac{y^2}{x}} = \frac{xz}{x^2 + y^2}$$

$$\boxed{f_y = \frac{xz}{x^2 + y^2}}$$

$$\boxed{f_z = \tan^{-1} \left(\frac{y}{x} \right)}$$

32. We have the following first-order partial derivatives for the function $f(x, y, z) = \tan^{-1} \left(\frac{xy}{z} \right)$:

$$f_x = \frac{1}{1 + \left(\frac{xy}{z} \right)^2} \left(\frac{y}{z} \right) = \frac{y}{z \left(1 + \frac{x^2 y^2}{z^2} \right)} = \frac{y}{z + \frac{x^2 y^2}{z}} = \frac{yz}{z^2 + x^2 y^2}$$

$$\boxed{f_x = \frac{yz}{z^2 + x^2 y^2}}$$

$$f_y = \frac{1}{1 + \left(\frac{xy}{z} \right)^2} \left(\frac{x}{z} \right) = \frac{x}{z \left(1 + \frac{x^2 y^2}{z^2} \right)} = \frac{x}{z + \frac{x^2 y^2}{z}} = \frac{xz}{z^2 + x^2 y^2}$$

$$\boxed{f_y = \frac{xz}{z^2 + x^2 y^2}}$$

$$f_z = \frac{1}{1 + \left(\frac{xy}{z} \right)^2} [xy(-z^{-2})] = \frac{-xy}{z^2 \left(1 + \frac{x^2 y^2}{z^2} \right)} = \frac{-xy}{z^2 + x^2 y^2}$$

$$\boxed{f_z = \frac{-xy}{z^2 + x^2 y^2}}$$

33. We have the following first-order partial derivatives for the function $f(x, y, z) = \sin[\ln(x^2 + y^2 + z^2)]$:

$$f_x = \cos[\ln(x^2 + y^2 + z^2)] \left(\frac{1}{x^2 + y^2 + z^2} \right) (2x) = \frac{2x \cos[\ln(x^2 + y^2 + z^2)]}{x^2 + y^2 + z^2}$$

$$\boxed{f_x = \frac{2x \cos[\ln(x^2 + y^2 + z^2)]}{x^2 + y^2 + z^2}}$$

$$f_y = \cos[\ln(x^2 + y^2 + z^2)] \left(\frac{1}{x^2 + y^2 + z^2} \right) (2y) = \frac{2y \cos[\ln(x^2 + y^2 + z^2)]}{x^2 + y^2 + z^2}$$

$$\boxed{f_y = \frac{2y \cos[\ln(x^2 + y^2 + z^2)]}{x^2 + y^2 + z^2}}$$

$$f_z = \cos[\ln(x^2 + y^2 + z^2)] \left(\frac{1}{x^2 + y^2 + z^2} \right) (2z) = \frac{2z \cos[\ln(x^2 + y^2 + z^2)]}{x^2 + y^2 + z^2}$$

$$f_z = \frac{2z \cos[\ln(x^2 + y^2 + z^2)]}{x^2 + y^2 + z^2}$$

34. We have the following first-order partial derivatives for the function $f(x, y, z) = e^{x^2+y^2} \ln z$:

$$f_x = e^{x^2+y^2} (2x) \ln z = 2xe^{x^2+y^2} \ln z$$

$$f_x = 2xe^{x^2+y^2} \ln z$$

$$f_y = e^{x^2+y^2} (2y) \ln z = 2ye^{x^2+y^2} \ln z$$

$$f_y = 2ye^{x^2+y^2} \ln z$$

$$f_z = e^{x^2+y^2} \left(\frac{1}{z} \right) = \frac{e^{x^2+y^2}}{z}$$

$$f_z = \frac{e^{x^2+y^2}}{z}$$

35.

$$\begin{aligned} f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x)^3 + 0}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x)^3}{(\Delta x)^2} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\Delta x}{\Delta x} = \lim_{\Delta x \rightarrow 0} 1 = 1 \end{aligned}$$

$$f_x(0, 0) = 1$$

$$\begin{aligned} f_y(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\frac{0 + (\Delta y)^3}{0 + (\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{\frac{(\Delta y)^3}{(\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{\Delta y}{\Delta y} = \lim_{\Delta y \rightarrow 0} 1 = 1 \end{aligned}$$

$$f_y(0, 0) = 1$$

36.

$$\begin{aligned} f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x)^2 \cdot 0}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} = \lim_{\Delta x \rightarrow 0} 0 = 0 \end{aligned}$$

$$f_x(0, 0) = 0$$

$$\begin{aligned} f_y(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\frac{0 \cdot (\Delta y)^2}{0 + 4(\Delta y)^3} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{0}{\Delta y} = \lim_{\Delta y \rightarrow 0} 0 = 0 \end{aligned}$$

$$f_y(0,0) = 0$$

37. The slope of the tangent line to the curve of intersection of $z = x^2 + y^2$ and $y = 2$ at any point is $f_x(x, 2) = 2x$. At the point $(1, 2, 5)$, the slope is 2. This tangent line lies on the plane $y = 2$. Symmetric equations of the tangent line are

$$z - 5 = \frac{x - 1}{1/2} \quad y = 2$$

38. The slope of the tangent line to the curve of intersection of $z = x^2 - y^2$ and $x = 3$ at any point is $f_y(3, y) = -2y$. At the point $(3, 1, 8)$, the slope is -2. This tangent line lies on the plane $x = 3$. Symmetric equations of the tangent line are

$$z - 8 = \frac{y - 1}{-1/2} \quad x = 3$$

39. The slope of the tangent line to the curve of intersection of $z = \sqrt{1 - x^2 - y^2}$ and $x = 0$ at any point can be found as follows:

$$\begin{aligned} f_y(0, y) &= \frac{1}{2}(1 - y^2)^{-1/2}(-2y) \\ &= \frac{-y}{\sqrt{1 - y^2}} \end{aligned}$$

At the point $(0, \frac{1}{2}, \frac{\sqrt{3}}{2})$, the slope is $-\frac{1}{\sqrt{3}}$. This tangent line lies on the plane $x = 0$. Symmetric equations of the tangent line are

$$z - \frac{\sqrt{3}}{2} = \frac{y - \frac{1}{2}}{-\sqrt{3}} \quad x = 0$$

40. The slope of the tangent line to the curve of intersection of $z = \sqrt{16 - x^2 - y^2}$ and $y = 2$ at any point can be found as follows:

$$f(x, 2) = \sqrt{16 - x^2 - 2^2} = \sqrt{12 - x^2}$$

so

$$f_x(x, 2) = \frac{1}{2}(12 - x^2)^{-1/2}(-2x) = \frac{-x}{\sqrt{12 - x^2}}$$

At the point $(\sqrt{3}, 2, 3)$, the slope is $\frac{-\sqrt{3}}{\sqrt{12 - (\sqrt{3})^2}} = \frac{-\sqrt{3}}{\sqrt{9}} = -\frac{\sqrt{3}}{3}$. This tangent line lies on the plane $y = 2$. Symmetric equations of the tangent line are

$$z - 3 = \frac{x - \sqrt{3}}{-\frac{3}{\sqrt{3}}} \quad y = 2$$

Since $\frac{3}{\sqrt{3}} = \frac{3\sqrt{3}}{\sqrt{3}\sqrt{3}} = \frac{3\sqrt{3}}{3} = \sqrt{3}$, we can rewrite these as

$$\boxed{z - 3 = \frac{x - \sqrt{3}}{-\sqrt{3}} \quad y = 2}$$

41. The slope of the tangent line to the curve of intersection of $z = \sqrt{x^2 + y^2}$ and $x = 4$ at any point can be found as follows:

$$f(4, y) = \sqrt{4^2 + y^2} = \sqrt{16 + y^2}$$

so

$$f_y(4, y) = \frac{1}{2}(16 + y^2)^{-1/2}(2y) = \frac{y}{\sqrt{16 + y^2}}$$

At the point $(4, 2, 2\sqrt{5})$, the slope is $\frac{2}{\sqrt{16 + 2^2}} = \frac{2}{\sqrt{20}} = \frac{2\sqrt{20}}{\sqrt{20}\sqrt{20}} = \frac{2\sqrt{20}}{20} = \frac{\sqrt{20}}{10} = \frac{2\sqrt{5}}{10} = \frac{\sqrt{5}}{5}$. This tangent line lies on the plane $x = 4$. Symmetric equations of the tangent line are

$$z - 2\sqrt{5} = \frac{y - 2}{\frac{5}{\sqrt{5}}} \quad x = 4$$

Since $\frac{5}{\sqrt{5}} = \frac{5\sqrt{5}}{\sqrt{5}\sqrt{5}} = \frac{5\sqrt{5}}{5} = \sqrt{5}$, we can rewrite these as

$$\boxed{z - 2\sqrt{5} = \frac{y - 2}{\sqrt{5}} \quad x = 4}$$

42. The slope of the tangent line to the curve of intersection of $z = e^x \ln e$ and $y = e$ at any point is $f_x(x, e) = e^x \ln e = e^x \cdot 1 = e^x$. At the point $(0, e, 1)$, the slope is $e^0 = 1$. This tangent line lies on the plane $y = e$. Symmetric equations of the tangent line are

$$z - 1 = \frac{x}{1} \quad y = e$$

or simplified as

$$\boxed{z - 1 = x \quad y = e}$$

43. (a) The rate of change of $z = \ln \sqrt{x^2 + y^2}$ at the point $(3, 4, \ln 5)$ in the direction of the positive x -axis can be found by evaluating the first partial derivative of z with respect to x at $(3, 4, \ln 5)$. Note that we can simplify the function first by applying a rule of logarithms to obtain $z = \ln(x^2 + y^2)^{1/2} = \frac{1}{2} \ln(x^2 + y^2)$. We then have

$$\frac{\partial z}{\partial x} = \frac{1}{2} \left[\frac{1}{x^2 + y^2} \right] (2x) = \frac{x}{x^2 + y^2}$$

so at the point $(3, 4, \ln 5)$,

$$\frac{\partial z}{\partial x} = \frac{3}{9 + 16} = \frac{3}{25}.$$

So, the rate of change of $z = \ln \sqrt{x^2 + y^2}$ at the point $(3, 4, \ln 5)$ in the direction of the positive

x -axis is $\boxed{\frac{3}{25}}$.

- (b) The rate of change of $z = \ln \sqrt{x^2 + y^2}$ at the point $(3, 4, \ln 5)$ in the direction of the positive y -axis can be found by evaluating the first partial derivative of z with respect to y at $(3, 4, \ln 5)$. Note that we can simplify the function first by applying a rule of logarithms to obtain $z = \ln(x^2 + y^2)^{1/2} = \frac{1}{2} \ln(x^2 + y^2)$. We then have

$$\frac{\partial z}{\partial y} = \frac{1}{2} \left[\frac{1}{x^2 + y^2} \right] (2y) = \frac{y}{x^2 + y^2}$$

so at the point $(3, 4, \ln 5)$,

$$\frac{\partial z}{\partial y} = \frac{4}{9 + 16} = \frac{4}{25}.$$

So, the rate of change of $z = \ln \sqrt{x^2 + y^2}$ at the point $(3, 4, \ln 5)$ in the direction of the positive y -axis is $\boxed{\frac{4}{25}}$.

44. (a) The rate of change of $z = e^y \sin x$ at the point $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$ in the direction of the positive x -axis can be found by evaluating the first partial derivative of z with respect to x at $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$. We have

$$\frac{\partial z}{\partial x} = e^y \cos x$$

so at the point $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$,

$$\frac{\partial z}{\partial x} = (e^0) \cos\left(\frac{\pi}{3}\right) = (1) \left(\frac{1}{2}\right) = \frac{1}{2}.$$

So, the rate of change of $z = e^y \sin x$ at the point $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$ in the direction of the positive x -axis is $\boxed{\frac{1}{2}}$.

- (b) The rate of change of $z = e^y \sin x$ at the point $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$ in the direction of the positive y -axis can be found by evaluating the first partial derivative of z with respect to y at $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$. We have

$$\frac{\partial z}{\partial y} = e^y \sin x$$

so at the point $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$,

$$\frac{\partial z}{\partial y} = (e^0) \sin\left(\frac{\pi}{3}\right) = (1) \left(\frac{\sqrt{3}}{2}\right) = \frac{\sqrt{3}}{2}.$$

So, the rate of change of $z = e^y \sin x$ at the point $\left(\frac{\pi}{3}, 0, \frac{\sqrt{3}}{2}\right)$ in the direction of the positive y -axis is $\boxed{\frac{\sqrt{3}}{2}}$.

Applications and Extensions

45. (a) On the circle $x^2 + y^2 = 1$, we have that $T(x, y) = \left(\frac{100}{\ln 2}\right) \ln 1 = \left(\frac{100}{\ln 2}\right) (0) = 0^\circ\text{C}$. On the circle $x^2 + y^2 = 4$, we have that $T(x, y) = \left(\frac{100}{\ln 2}\right) \ln 4 = \left(\frac{100}{\ln 2}\right) \ln 2^2 = \left(\frac{100}{\ln 2}\right) 2 \ln 2 = 200^\circ\text{C}$.

- (b) We can find the rate of change of T in the direction of the positive x -axis at (1,2) and (2,1) by finding the first partial derivative of T with respect to x and then evaluating at (1,2) and (2,1) respectively. We have

$$T_x = \left(\frac{100}{\ln 2}\right) \left(\frac{1}{x^2 + y^2}\right) (2x) = \left(\frac{200}{\ln 2}\right) \left(\frac{x}{x^2 + y^2}\right)$$

Then, $T_x(1, 2) = \left(\frac{200}{\ln 2}\right) \left(\frac{1}{1^2 + 2^2}\right) = \frac{200}{5 \ln 2} = \frac{40}{\ln 2}$, or just $\boxed{T_x(1, 2) = \frac{40}{\ln 2} \approx 57.708}$. For every unit increase in the direction of the positive x -axis from the point (1, 2), there is an increase in the temperature of the plate of approximately 58°C . We also have $T_x(2, 1) = \left(\frac{200}{\ln 2}\right) \left(\frac{2}{2^2 + 1^2}\right) = \frac{400}{5 \ln 2} = \frac{80}{\ln 2}$, or just $\boxed{T_x(2, 1) = \frac{80}{\ln 2} \approx 115.416}$. For every unit increase in the direction of the positive x -axis from the point (2,1), there is an increase in the temperature of the plate of approximately 115°C .

- (c) We can find the rate of change of T in the direction of the positive y -axis at (2,0) and (0,2) by finding the first partial derivative of T with respect to y and then evaluating at (2,0) and (0,2) respectively. We have

$$T_y = \left(\frac{100}{\ln 2}\right) \left(\frac{1}{x^2 + y^2}\right) (2y) = \left(\frac{200}{\ln 2}\right) \left(\frac{y}{x^2 + y^2}\right)$$

Then, $T_y(2, 0) = \left(\frac{200}{\ln 2}\right) \left(\frac{0}{2^2 + 0^2}\right) = 0$, or just $\boxed{T_y(2, 0) = 0}$. Since the rate of change is 0, the temperature is neither increasing nor decreasing for any increase (or decrease) in the direction of the positive y -axis from the point (2,0). We also have $T_y(0, 2) = \left(\frac{200}{\ln 2}\right) \left(\frac{2}{0^2 + 2^2}\right) = \frac{200}{\ln 2} \left(\frac{1}{2}\right) = \frac{100}{\ln 2}$, or just $\boxed{T_y(0, 2) = \frac{100}{\ln 2} \approx 144.27}$. For every unit increase in the direction of the positive y -axis from the point (0,2), there is an increase in the temperature of the plate of approximately 144°C .

46. (a) On the circle $x^2 + y^2 = 1$, we have that $T(x, y) = \frac{100}{\sqrt{1}} = 100^\circ\text{C}$. On the circle $x^2 + y^2 = 4$, we have that $T(x, y) = \frac{100}{\sqrt{4}} = \frac{100}{2} = 50^\circ\text{C}$.

- (b) We can find the rate of change of T in the direction of the positive x -axis at $(1,0)$ and $(0,1)$ by finding the first partial derivative of T with respect to x and then evaluating at $(1,0)$ and $(0,1)$ respectively. We have

$$T_x = 100(-\frac{1}{2})(x^2 + y^2)^{-3/2}(2x) = \frac{-100x}{(x^2 + y^2)^{3/2}}$$

Then, $T_x(1,0) = \frac{-100(1)}{(1^2 + 0^2)^{3/2}} = -100$, or just $\boxed{T_x(1,0) = -100}$. For every unit increase in the direction of the positive x -axis from the point $(1,0)$, there is a decrease in the temperature of the plate of approximately 100°C . We also have $T_x(0,1) = \frac{-100(0)}{(0^2 + 1^2)^{3/2}} = 0$, or just $\boxed{T_x(0,1) = 0}$. Since the rate of change is 0, the temperature is neither increasing nor decreasing for any increase (or decrease) in the direction of the positive x -axis from the point $(0,1)$.

- (c) We can find the rate of change of T in the direction of the positive y -axis at $(2,0)$ and $(0,2)$ by finding the first partial derivative of T with respect to y and then evaluating at $(2,0)$ and $(0,2)$ respectively. We have

$$T_y = 100(-\frac{1}{2})(x^2 + y^2)^{-3/2}(2y) = \frac{-100y}{(x^2 + y^2)^{3/2}}$$

Then, $T_y(2,0) = \frac{-100(0)}{(2^2 + 0^2)^{3/2}} = 0$, or just $\boxed{T_y(2,0) = 0}$. Since the rate of change is 0, the temperature is neither increasing nor decreasing for any increase (or decrease) in the direction of the positive y -axis from the point $(2,0)$. We also have $T_y(0,2) = \frac{-100(2)}{(0^2 + 2^2)^{3/2}} = -\frac{200}{4^{3/2}} = -\frac{200}{8} = -25$, or just $\boxed{T_y(0,2) = -25}$. For every unit increase in the direction of the positive y -axis from the point $(0,2)$, there is a decrease in the temperature of the plate of approximately 25°C .

47. We consider the equation $PV = nrT$, and assume that none of P, V, n, r , or T are 0 since this would result in a trivial situation. We find $\frac{\partial V}{\partial T}$, $\frac{\partial T}{\partial P}$, and $\frac{\partial P}{\partial V}$, and show that their product is -1. To find these partials, we solve for V , T , and then P in the equation $PV = nrT$.

$$V = \frac{nrT}{P}$$

so

$$\frac{\partial V}{\partial T} = \frac{nr}{P}.$$

Also,

$$T = \frac{PV}{nr}$$

so

$$\frac{\partial T}{\partial P} = \frac{V}{nr}.$$

Lastly,

$$P = \frac{nrT}{V}$$

so

$$\frac{\partial P}{\partial V} = nrT(-1 \cdot V^{-2}) = -\frac{nrT}{V^2}.$$

Multiplying gives us $\frac{\partial V}{\partial T} \cdot \frac{\partial T}{\partial P} \cdot \frac{\partial P}{\partial V} = \left(\frac{nr}{P}\right) \left(\frac{V}{nr}\right) \left(-\frac{nrT}{V^2}\right) = -\frac{nrT}{PV} = -\frac{PV}{PV} = -1$.

48. (a) $\boxed{\frac{\partial V}{\partial T} = \frac{k}{P}}$ and $\frac{\partial V}{\partial P} = k(T)(-1 \cdot P^{-2}) = -\frac{kT}{P^2}$, so $\boxed{\frac{\partial V}{\partial P} = -\frac{kT}{P^2}}$.

(b) We have that $T \frac{\partial V}{\partial T} + P \frac{\partial V}{\partial P} = T \left(\frac{k}{P}\right) + P \left(-\frac{kT}{P^2}\right) = \frac{kT}{P} - \frac{kT}{P} = 0$.

49. (a) The marginal productivity with respect to capital input K is the partial derivative $\frac{\partial P}{\partial K}$, which is the following:

$$\frac{\partial P}{\partial K} \approx (1.01)(0.25)K^{-0.75}L^{0.75} = 0.2525K^{-0.75}L^{0.75}$$

When $K = 107$ and $L = 105$, we obtain that $\frac{\partial P}{\partial K} \approx 0.2525(107)^{-0.75}(105)^{0.75}$

so

$$\boxed{\frac{\partial P}{\partial K} \approx 0.249}$$

The marginal productivity with respect to labor input L is the partial derivative $\frac{\partial P}{\partial L}$, which is the following:

$$\frac{\partial P}{\partial L} \approx (1.01)(0.75)K^{0.25}L^{-0.25} = 0.7575K^{0.25}L^{-0.25}$$

When $K = 107$ and $L = 105$, we obtain that $\frac{\partial P}{\partial L} \approx 0.7575(107)^{0.25}(105)^{-0.25}$

so

$$\boxed{\frac{\partial P}{\partial L} \approx 0.761}$$

- (b) The marginal productivity with respect to capital input K is the partial derivative $\frac{\partial P}{\partial K}$, which is the following:

$$\frac{\partial P}{\partial K} \approx (1.01)(0.25)K^{-0.75}L^{0.75} = 0.2525K^{-0.75}L^{0.75}$$

When $K = 407$ and $L = 193$, we obtain that $\frac{\partial P}{\partial K} \approx 0.2525(407)^{-0.75}(193)^{0.75}$

so

$$\boxed{\frac{\partial P}{\partial K} \approx 0.144}$$

The marginal productivity with respect to labor input L is the partial derivative $\frac{\partial P}{\partial L}$, which is the following:

$$\frac{\partial P}{\partial L} \approx (1.01)(0.75)K^{0.25}L^{-0.25} = 0.7575K^{0.25}L^{-0.25}$$

When $K = 407$ and $L = 193$, we obtain that $\frac{\partial P}{\partial L} \approx 0.7575(407)^{0.25}(193)^{-0.25}$

so

$$\boxed{\frac{\partial P}{\partial L} \approx 0.913}$$

(c) Answers will vary.

50. (a) $f(0.25, 0.04, 0.05) = \frac{1 + (1 - 0.25)0.04}{1 + 0.05} - 1$

$$\boxed{f(0.25, 0.04, 0.05) \approx -0.019}$$

(b) The rate of change of gain (or loss) of money with respect to the marginal tax rate will be given by the partial derivative $\frac{\partial z}{\partial x}$. We first rewrite the expression for z as follows:

$$z = \frac{1 + (1 - x)y}{1 + r} - 1 = \frac{1 + y - xy}{1 + r} - 1 = \frac{1 + y}{1 + r} - \frac{xy}{1 + r} - 1$$

Then

$$\frac{\partial z}{\partial x} = -\frac{y}{1 + r}$$

So, when the effective yield y is 4%, or 0.04, and the inflation rate r is 5%, or 0.05, we have

$$\frac{\partial z}{\partial x} = -\frac{0.04}{1 + 0.05}, \text{ or } \boxed{\frac{\partial z}{\partial x} \approx -0.038}.$$

(c) The rate of change of gain (or loss) of money with respect to the effective yield will be given by the partial derivative $\frac{\partial z}{\partial y}$. We first rewrite the expression for z as follows:

$$z = \frac{1 + (1 - x)y}{1 + r} - 1 = \frac{1}{1 + r} + \frac{(1 - x)y}{1 + r} - 1$$

Then

$$\frac{\partial z}{\partial y} = \frac{1 - x}{1 + r}$$

So, when the marginal tax rate x is 25%, or 0.25, and the inflation rate r is 5%, or 0.05, we have

$$\frac{\partial z}{\partial y} = \frac{1 - 0.25}{1 + 0.05}, \text{ or } \boxed{\frac{\partial z}{\partial y} \approx 0.714}.$$

- (d) The rate of change of gain (or loss) of money with respect to the inflation rate will be given by the partial derivative $\frac{\partial z}{\partial r}$. We have that

$$\frac{\partial z}{\partial r} = [1 + (1 - x)y] \cdot [-1 \cdot (1 + r)^{-2}] = -\frac{1 + (1 - x)y}{(1 + r)^2}$$

So, when the marginal tax rate x is 25%, or 0.25, the effective yield y is 4%, or 0.04, and the annual inflation rate r is 5%, or 0.05, we have $\frac{\partial z}{\partial r} = -\frac{1 + (1 - 0.25)0.04}{(1.05)^2}$, or $\boxed{\frac{\partial z}{\partial r} \approx -0.934}$.

51. The marginal productivity with respect to x , the marginal productivity with respect to y , and the marginal productivity with respect to z will be given by the partial derivatives $\frac{\partial w}{\partial x}$, $\frac{\partial w}{\partial y}$, and $\frac{\partial w}{\partial z}$ respectively. We have

$$\frac{\partial w}{\partial x} = 2 \cdot \frac{1}{2} x^{-1/2} y^{1/3} z^{1/6}$$

$$\boxed{\frac{\partial w}{\partial x} = \frac{y^{1/3} z^{1/6}}{x^{1/2}}}$$

$$\frac{\partial w}{\partial y} = 2 \cdot \frac{1}{3} x^{1/2} y^{-2/3} z^{1/6}$$

$$\boxed{\frac{\partial w}{\partial y} = \frac{2x^{1/2} z^{1/6}}{3y^{2/3}}}$$

$$\frac{\partial w}{\partial z} = 2 \cdot \frac{1}{6} x^{1/2} y^{1/3} z^{-5/6}$$

$$\boxed{\frac{\partial w}{\partial z} = \frac{x^{1/2} y^{1/3}}{3z^{5/6}}}$$

52. We have that

$$\frac{\partial v}{\partial p} = k \left(\frac{1}{2} \right) \left(\frac{p}{d} \right)^{-1/2} \frac{1}{d}$$

$$\boxed{\frac{\partial v}{\partial p} = \frac{k}{2d} \sqrt{\frac{d}{p}}}$$

and

$$\frac{\partial v}{\partial d} = k \left(\frac{1}{2} \right) \left(\frac{p}{d} \right)^{-1/2} (p \cdot (-d^{-2}))$$

$$\boxed{\frac{\partial v}{\partial d} = -\frac{kp}{2d^2} \sqrt{\frac{d}{p}}}$$

53. We compute $\frac{\partial^2 f}{\partial t^2}$ and $\frac{\partial^2 f}{\partial x^2}$ to show that $\frac{\partial^2 f}{\partial t^2} = 25 \frac{\partial^2 f}{\partial x^2}$. We have

$$\frac{\partial f}{\partial t} = 2(-\sin(5t) \cdot 5) \sin x = -10 \sin(5t) \sin x$$

$$\frac{\partial^2 f}{\partial t^2} = -10(\cos(5t) \cdot 5) \sin x = -50 \cos(5t) \sin x$$

and

$$\frac{\partial f}{\partial x} = 2 \cos(5t) \cos x$$

$$\frac{\partial^2 f}{\partial x^2} = 2 \cos(5t)(-\sin x) = -2 \cos(5t) \sin x$$

so

$$\frac{\partial^2 f}{\partial t^2} = -50 \cos(5t) \sin x = 25(-2 \cos(5t) \sin x) = 25 \frac{\partial^2 f}{\partial x^2} \text{ at all points } (x, t). \quad \checkmark$$

54. (a) We first show that $T_t = -\lambda T$. We have that

$$\begin{aligned} T_t &= 40(-\lambda e^{-\lambda t}) \sin\left(\frac{\pi x}{20}\right) \\ &= -\lambda \left[40e^{-\lambda t} \sin\left(\frac{\pi x}{20}\right) \right] = -\lambda T. \quad \checkmark \end{aligned}$$

Next, we show that $T_{xx} = -\frac{\pi^2}{400}T$. We have that

$$\begin{aligned} T_x &= 40e^{-\lambda t} \cos\left(\frac{\pi x}{20}\right) \left(\frac{\pi}{20}\right) = 2\pi e^{-\lambda t} \cos\left(\frac{\pi x}{20}\right) \\ T_{xx} &= 2\pi e^{-\lambda t} \left[-\sin\left(\frac{\pi x}{20}\right) \left(\frac{\pi}{20}\right) \right] = -\frac{\pi^2}{10} e^{-\lambda t} \sin\left(\frac{\pi x}{20}\right) \quad \text{and} \\ -\frac{\pi^2}{400}T &= -\frac{\pi^2}{400} \left[40e^{-\lambda t} \sin\left(\frac{\pi x}{20}\right) \right] = -\frac{\pi^2}{10} e^{-\lambda t} \sin\left(\frac{\pi x}{20}\right) = T_{xx} \quad \checkmark \end{aligned}$$

Lastly, we show that $T_t = \frac{1}{k^2}T_{xx}$ for some constant k . We have already computed that

$$T_t = -40\lambda e^{-\lambda t} \sin\left(\frac{\pi x}{20}\right) \text{ and } T_{xx} = -\frac{\pi^2}{10} e^{-\lambda t} \sin\left(\frac{\pi x}{20}\right), \text{ and so}$$

$$T_t = \frac{40\lambda}{\frac{\pi^2}{10}} T_{xx} = \frac{1}{\frac{\pi^2}{400\lambda}} T_{xx} \text{ (using } \lambda \neq 0 \text{). Letting } k = \frac{\pi}{20\sqrt{\lambda}} \text{ yields } T_t = \frac{1}{k^2} T_{xx} \text{ as desired (and } k \text{ is a constant since } \pi \text{ and } \lambda \text{ are also constants).}$$

(b) The graph of $y = T(0, x) = 40 \sin\left(\frac{\pi x}{20}\right)$ is shown below on $0 \leq x \leq 20$.

55. $\boxed{\frac{\partial x}{\partial r} = \cos \theta}$

$$\frac{\partial x}{\partial \theta} = r(-\sin \theta) \text{ so}$$

$$\boxed{\frac{\partial x}{\partial \theta} = -r \sin \theta}$$

$$\boxed{\frac{\partial y}{\partial r} = \sin \theta}$$

$$\boxed{\frac{\partial y}{\partial \theta} = r \cos \theta}$$

56. $\frac{\partial r}{\partial x} = \frac{1}{2}(x^2 + y^2)^{-1/2}(2x) = \frac{\partial r}{\partial x} = \frac{x}{\sqrt{x^2 + y^2}}$

$$\boxed{\frac{\partial r}{\partial x} = \frac{x}{\sqrt{x^2 + y^2}}}$$

$$\frac{\partial \theta}{\partial x} = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot y(-x^{-2}) = \frac{-y}{x^2 \left[1 + \frac{y^2}{x^2}\right]} = \frac{\partial \theta}{\partial x} = \frac{-y}{x^2 + y^2}$$

$$\boxed{\frac{\partial \theta}{\partial x} = \frac{-y}{x^2 + y^2}}$$

$$\frac{\partial r}{\partial y} = \frac{1}{2}(x^2 + y^2)^{-1/2}(2y) = \frac{\partial r}{\partial y} = \frac{y}{\sqrt{x^2 + y^2}}$$

$$\boxed{\frac{\partial r}{\partial y} = \frac{y}{\sqrt{x^2 + y^2}}}$$

$$\frac{\partial \theta}{\partial y} = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{1}{x} = \frac{1}{x \left[1 + \frac{y^2}{x^2}\right]} = \frac{1}{x + \frac{y^2}{x}} = \frac{\partial \theta}{\partial y} = \frac{x}{x^2 + y^2}$$

$$\boxed{\frac{\partial \theta}{\partial y} = \frac{x}{x^2 + y^2}}$$

57. (a) Below are the graphs of $f(x, y) = \frac{1}{2}x^2 + \frac{1}{3}y^2$ and $y = 1$.

- (b) The slope of the tangent line to the curve of intersection of $z = \frac{1}{2}x^2 + \frac{1}{3}y^2$ and $y = 1$ at any point is $f_x(x, 1) = x$. At the point $\left(2, 1, \frac{7}{3}\right)$, the slope is 2. This tangent line lies on the plane $y = 1$. Symmetric equations of the tangent line are

$$\boxed{z - \frac{7}{3} = \frac{x - 2}{\frac{1}{2}} \quad y = 1}$$

58. (a) Below are the graphs of $f(x, y) = \frac{5}{\sqrt{x^2 + y^2 + 1}}$ and $x = 1$.

- (b) The slope of the tangent line to the curve of intersection of $z = \frac{5}{\sqrt{x^2 + y^2 + 1}}$ and $x = 1$ at any point is $f_y(1, y) = 5 \cdot \left[-\frac{1}{2}(1^2 + y^2 + 1)^{-3/2}(2y)\right] = \frac{-5y}{(2 + y^2)^{3/2}}$. At the point $\left(1, -2, \frac{5\sqrt{6}}{6}\right)$, the slope is $\frac{-5(-2)}{(2 + (-2)^2)^{3/2}} = \frac{10}{6^{3/2}} = \frac{10}{6\sqrt{6}} = \frac{5}{3\sqrt{6}}$. This tangent line lies on the plane $x = 1$. Symmetric equations of the tangent line are

$$\boxed{z - \frac{5\sqrt{6}}{6} = \frac{y + 2}{\frac{3\sqrt{6}}{5}} \quad x = 1}$$

59. We have that

$$\frac{\partial u}{\partial x} = e^x \cos y \text{ and } \frac{\partial v}{\partial y} = e^x \cos y \text{ so } \frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}. \quad \checkmark$$

Also,

$$\frac{\partial u}{\partial y} = e^x(-\sin y) = -e^x \sin y \text{ and } \frac{\partial v}{\partial x} = e^x \sin y \text{ so } \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \quad \checkmark$$

60. To find $\frac{\partial u}{\partial x}$ and $\frac{\partial u}{\partial y}$, we first apply a rule of logarithms to rewrite u as $u = \ln(x^2 + y^2)^{1/2} = \frac{1}{2} \ln(x^2 + y^2)$. We then have that

$$\frac{\partial u}{\partial x} = \frac{1}{2} \cdot \frac{1}{x^2 + y^2} (2x) = \frac{x}{x^2 + y^2} \text{ and}$$

$$\frac{\partial u}{\partial y} = \frac{1}{2} \cdot \frac{1}{x^2 + y^2} (2y) = \frac{y}{x^2 + y^2}.$$

We also have that, for $x \neq 0$, $\frac{\partial v}{\partial y} = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{1}{x} = \frac{1}{x \left[1 + \frac{y^2}{x^2}\right]} = \frac{1}{x + \frac{y^2}{x}} = \frac{x}{x^2 + y^2} = \frac{\partial u}{\partial x}$, and so

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}. \quad \checkmark$$

Lastly, we have, for $x \neq 0$, $\frac{\partial v}{\partial x} = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot y(-x^{-2}) = \frac{-y}{x^2 \left[1 + \frac{y^2}{x^2}\right]} = \frac{-y}{x^2 + y^2} = -\frac{\partial u}{\partial y}$, and so

$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \quad \checkmark$$

61. We have that $\frac{\partial u}{\partial x} = 2x$ and $\frac{\partial u}{\partial y} = 8y$, so

$$x \frac{\partial u}{\partial x} + y \frac{\partial u}{\partial y} = x(2x) + y(8y) = 2x^2 + 8y^2 = 2(x^2 + 4y^2) = 2u. \quad \checkmark$$

62. We have that $\frac{\partial u}{\partial x} = y^2$ and $\frac{\partial u}{\partial y} = 2xy$, so

$$x \frac{\partial u}{\partial x} + y \frac{\partial u}{\partial y} = x(y^2) + y(2xy) = xy^2 + 2xy^2 = 3xy^2 = 3u. \quad \checkmark$$

63. We have that $\frac{\partial w}{\partial x} = 2x$, $\frac{\partial w}{\partial y} = 2y - 3z$, and $\frac{\partial w}{\partial z} = -3y$, so

$$\begin{aligned} x \frac{\partial w}{\partial x} + y \frac{\partial w}{\partial y} + z \frac{\partial w}{\partial z} &= x(2x) + y(2y - 3z) + z(-3y) = 2x^2 + 2y^2 - 3yz - 3yz = 2x^2 + 2y^2 - 6yz \\ &= 2(x^2 + y^2 - 3yz) = 2w. \quad \checkmark \end{aligned}$$

64. We first rewrite w to reduce the computations in finding the partial derivatives. We have

$$w = \frac{xz + y^2}{yz} = \frac{xz}{yz} + \frac{y^2}{yz} = \frac{x}{y} + \frac{y}{z}.$$

This yields $\frac{\partial w}{\partial x} = \frac{1}{y}$, $\frac{\partial w}{\partial y} = x(-y^{-2}) + \frac{1}{z} = -\frac{x}{y^2} + \frac{1}{z}$, and $\frac{\partial w}{\partial z} = y(-z^{-2}) = -\frac{y}{z^2}$, so

$$x \frac{\partial w}{\partial x} + y \frac{\partial w}{\partial y} + z \frac{\partial w}{\partial z} = x \left(\frac{1}{y} \right) + y \left(-\frac{x}{y^2} + \frac{1}{z} \right) + z \left(-\frac{y}{z^2} \right) = \frac{x}{y} - \frac{x}{y} + \frac{y}{z} - \frac{y}{z} = 0. \quad \checkmark$$

65. We have that $\frac{\partial z}{\partial x} = -\sin(x + y) - \sin(x - y)$, and $\frac{\partial^2 z}{\partial x^2} = -\cos(x + y) - \cos(x - y)$. Also,

$$\frac{\partial z}{\partial y} = -\sin(x+y) - \sin(x-y)(-1) = -\sin(x+y) + \sin(x-y),$$

and

$$\frac{\partial^2 z}{\partial y^2} = -\cos(x+y) + \cos(x-y)(-1) = -\cos(x+y) - \cos(x-y).$$

So,

$$\begin{aligned} \frac{\partial^2 z}{\partial x^2} - \frac{\partial^2 z}{\partial y^2} &= -\cos(x+y) - \cos(x-y) - [-\cos(x+y) - \cos(x-y)] \\ &= -\cos(x+y) - \cos(x-y) + \cos(x+y) + \cos(x-y) = 0. \quad \checkmark \end{aligned}$$

66. We have that

$$\frac{\partial z}{\partial x} = \cos(x-y) + \frac{1}{x+y}, \text{ and } \frac{\partial^2 z}{\partial x^2} = -\sin(x-y) + [-(x+y)^{-2}] = -\sin(x-y) - \frac{1}{(x+y)^2}.$$

Also,

$$\frac{\partial z}{\partial y} = \cos(x-y)(-1) + \frac{1}{x+y} = -\cos(x-y) + \frac{1}{x+y},$$

and

$$\frac{\partial^2 z}{\partial y^2} = -[-\sin(x-y)(-1)] + [-(x+y)^{-2}] = -\sin(x-y) - \frac{1}{(x+y)^2},$$

So,

$$\frac{\partial^2 z}{\partial x^2} = -\sin(x-y) - \frac{1}{(x+y)^2} = \frac{\partial^2 z}{\partial y^2}. \quad \checkmark$$

67. We have $\frac{\partial u}{\partial t} = e^{-\alpha^2 t}(-\alpha^2)\sin(\alpha x) = -\alpha^2 e^{-\alpha^2 t} \sin(\alpha x)$. Also,

$$\frac{\partial u}{\partial x} = e^{-\alpha^2 t} \cos(\alpha x) \cdot \alpha = \alpha e^{-\alpha^2 t} \cos(\alpha x) \text{ and}$$

$$\frac{\partial^2 u}{\partial x^2} = \alpha e^{-\alpha^2 t} [-\sin(\alpha x) \cdot \alpha] = -\alpha^2 e^{-\alpha^2 t} \sin(\alpha x). \text{ So,}$$

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2}, \text{ for any constant } \alpha. \quad \checkmark$$

68.

$$\begin{aligned} \frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} \left(\ln \sqrt{x^2 + y^2} \right) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial x} \left(\sqrt{x^2 + y^2} \right) \\ &= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial x} \left((x^2 + y^2)^{1/2} \right) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \frac{\partial}{\partial x} (x^2 + y^2) \\ &= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot (2x + 0) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{x^2 + y^2}} \cdot 2x = \frac{x}{x^2 + y^2} \end{aligned}$$

$$\begin{aligned}
\frac{\partial^2 z}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial z}{\partial x} \right) = \frac{\partial}{\partial x} \left(\frac{x}{x^2 + y^2} \right) = \frac{\left(\frac{\partial}{\partial x} (x) \right) (x^2 + y^2) - x \left(\frac{\partial}{\partial x} (x^2 + y^2) \right)}{(x^2 + y^2)^2} \\
&= \frac{1 \cdot (x^2 + y^2) - x \cdot (2x + 0)}{(x^2 + y^2)^2} = \frac{x^2 + y^2 - 2x^2}{(x^2 + y^2)^2} = \frac{-x^2 + y^2}{(x^2 + y^2)^2}
\end{aligned}$$

$$\begin{aligned}
\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} \left(\ln \sqrt{x^2 + y^2} \right) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial y} \left(\sqrt{x^2 + y^2} \right) \\
&= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{\partial}{\partial y} \left((x^2 + y^2)^{1/2} \right) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \frac{\partial}{\partial y} (x^2 + y^2) \\
&= \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot (0 + 2y) = \frac{1}{\sqrt{x^2 + y^2}} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{x^2 + y^2}} \cdot 2y = \frac{y}{x^2 + y^2}
\end{aligned}$$

$$\begin{aligned}
\frac{\partial^2 z}{\partial y^2} &= \frac{\partial}{\partial y} \left(\frac{\partial z}{\partial y} \right) = \frac{\partial}{\partial y} \left(\frac{y}{x^2 + y^2} \right) = \frac{\left(\frac{\partial}{\partial y} (y) \right) (x^2 + y^2) - y \left(\frac{\partial}{\partial y} (x^2 + y^2) \right)}{(x^2 + y^2)^2} \\
&= \frac{1 \cdot (x^2 + y^2) - y \cdot (0 + 2y)}{(x^2 + y^2)^2} = \frac{x^2 + y^2 - 2y^2}{(x^2 + y^2)^2} = \frac{x^2 - y^2}{(x^2 + y^2)^2}
\end{aligned}$$

Adding up the two, we get:

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = \frac{-x^2 + y^2}{(x^2 + y^2)^2} + \frac{x^2 - y^2}{(x^2 + y^2)^2} = \frac{-x^2 + y^2 + x^2 - y^2}{(x^2 + y^2)^2} = \frac{0}{(x^2 + y^2)^2} = 0,$$

which means that the function $z = \ln \sqrt{x^2 + y^2}$ is a harmonic function.

69.

$$\frac{\partial z}{\partial x} = \frac{\partial}{\partial x} (e^{ax} \sin(ay)) = \sin(ay) \cdot \frac{\partial}{\partial x} (e^{ax}) = \sin(ay) \cdot e^{ax} \cdot \frac{\partial}{\partial x} (ax) = \sin(ay) \cdot e^{ax} \cdot a = ae^{ax} \sin(ay)$$

$$\begin{aligned}
\frac{\partial^2 z}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial z}{\partial x} \right) = \frac{\partial}{\partial x} (ae^{ax} \sin(ay)) \\
&= a \sin(ay) \cdot \frac{\partial}{\partial x} (e^{ax}) = a \sin(ay) \cdot e^{ax} \cdot \frac{\partial}{\partial x} (ax) = a \sin(ay) \cdot e^{ax} \cdot a = a^2 e^{ax} \sin(ay)
\end{aligned}$$

$$\frac{\partial z}{\partial y} = \frac{\partial}{\partial y} (e^{ax} \sin(ay)) = e^{ax} \cdot \frac{\partial}{\partial y} (\sin(ay)) = e^{ax} \cdot \cos(ay) \cdot \frac{\partial}{\partial y} (ay) = e^{ax} \cdot \cos(ay) \cdot a = ae^{ax} \cos(ay)$$

$$\begin{aligned}
\frac{\partial^2 z}{\partial y^2} &= \frac{\partial}{\partial y} \left(\frac{\partial z}{\partial y} \right) = \frac{\partial}{\partial y} (ae^{ax} \cos(ay)) \\
&= ae^{ax} \cdot \frac{\partial}{\partial y} (\cos(ay)) = ae^{ax} \cdot (-\sin(ay)) \cdot \frac{\partial}{\partial y} (ay) = ae^{ax} \cdot (-\sin(ay)) \cdot a = -a^2 e^{ax} \sin(ay)
\end{aligned}$$

Adding up the two, we get:

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = a^2 e^{ax} \sin(ay) - a^2 e^{ax} \sin(ay) = 0,$$

which means that the function $z = e^{ax} \sin(ay)$ is a harmonic function.

70. For $x \neq 0$,

$$\begin{aligned}\frac{\partial z}{\partial x} &= \frac{\partial}{\partial x} \left(\tan^{-1} \frac{y}{x} \right) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{\partial}{\partial x} \left(\frac{y}{x} \right) \\ &= \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot y \cdot \frac{\partial}{\partial x} (x^{-1}) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot y \cdot (-x^{-2}) = \frac{x^2}{x^2 + y^2} \cdot \frac{-y}{x^2} = \frac{-y}{x^2 + y^2}\end{aligned}$$

$$\begin{aligned}\frac{\partial^2 z}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial z}{\partial x} \right) = \frac{\partial}{\partial x} \left(\frac{-y}{x^2 + y^2} \right) = -y \cdot \frac{\partial}{\partial x} ((x^2 + y^2)^{-1}) \\ &= -y \cdot (-1(x^2 + y^2)^{-2}) \cdot \frac{\partial}{\partial x} (x^2 + y^2) = y(x^2 + y^2)^{-2} \cdot (2x + 0) = \frac{2xy}{(x^2 + y^2)^2}\end{aligned}$$

$$\begin{aligned}\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} \left(\tan^{-1} \frac{y}{x} \right) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{\partial}{\partial y} \left(\frac{y}{x} \right) \\ &= \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{1}{x} \cdot \frac{\partial}{\partial y} (y) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{1}{x} \cdot 1 = \frac{x^2}{x^2 + y^2} \cdot \frac{1}{x} = \frac{x}{x^2 + y^2}\end{aligned}$$

$$\begin{aligned}\frac{\partial^2 z}{\partial y^2} &= \frac{\partial}{\partial y} \left(\frac{\partial z}{\partial y} \right) = \frac{\partial}{\partial y} \left(\frac{x}{x^2 + y^2} \right) = x \cdot \frac{\partial}{\partial y} ((x^2 + y^2)^{-1/2}) \\ &= x \cdot (-1(x^2 + y^2)^{-2}) \cdot \frac{\partial}{\partial y} (x^2 + y^2) = -x(x^2 + y^2)^{-2} \cdot (0 + 2y) = \frac{-2xy}{(x^2 + y^2)^2}\end{aligned}$$

Adding up the two, we get:

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = \frac{2xy}{(x^2 + y^2)^2} + \frac{-2xy}{(x^2 + y^2)^2} = \frac{2xy - 2xy}{(x^2 + y^2)^2} = \frac{0}{(x^2 + y^2)^2} = 0,$$

which means that the function $z = \tan^{-1} \frac{y}{x}$ is a harmonic function.

71.

$$\frac{\partial z}{\partial x} = \frac{\partial}{\partial x} (e^{ax} \cos(ay)) = \cos(ay) \cdot \frac{\partial}{\partial x} (e^{ax}) = \cos(ay) \cdot e^{ax} \cdot \frac{\partial}{\partial x} (ax) = \cos(ay) \cdot e^{ax} \cdot a = ae^{ax} \cos(ay)$$

$$\begin{aligned}\frac{\partial^2 z}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial z}{\partial x} \right) = \frac{\partial}{\partial x} (ae^{ax} \cos(ay)) \\ &= a \cos(ay) \cdot \frac{\partial}{\partial x} (e^{ax}) = a \cos(ay) \cdot e^{ax} \cdot \frac{\partial}{\partial x} (ax) = a \cos(ay) \cdot e^{ax} \cdot a = a^2 e^{ax} \cos(ay)\end{aligned}$$

$$\begin{aligned}\frac{\partial z}{\partial y} &= \frac{\partial}{\partial y} (e^{ax} \cos(ay)) \\ &= e^{ax} \cdot \frac{\partial}{\partial y} (\cos(ay)) = e^{ax} \cdot (-\sin(ay)) \cdot \frac{\partial}{\partial y} (ay) = e^{ax} \cdot (-\sin(ay)) \cdot a = -ae^{ax} \sin(ay)\end{aligned}$$

$$\begin{aligned}\frac{\partial^2 z}{\partial y^2} &= \frac{\partial}{\partial y} \left(\frac{\partial z}{\partial y} \right) = \frac{\partial}{\partial y} (-ae^{ax} \sin(ay)) \\ &= -ae^{ax} \cdot \frac{\partial}{\partial y} (\sin(ay)) = -ae^{ax} \cdot \cos(ay) \cdot \frac{\partial}{\partial y} (ay) = -ae^{ax} \cdot \cos(ay) \cdot a = -a^2 e^{ax} \cos(ay)\end{aligned}$$

Adding up the two, we get:

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = a^2 e^{ax} \cos(ay) - a^2 e^{ax} \cos(ay) = 0,$$

which means that the function $z = e^{ax} \cos(ay)$ is a harmonic function.

72. Since $u(x, y)$ and $v(x, y)$ have continuous second-order partial derivatives, we can apply the theorem on the Equality of Mixed Partial (Clairaut's Theorem), and conclude that $u_{xy} = u_{yx}$ and $v_{xy} = v_{yx}$. To show that u is a harmonic function, we compute $u_{xx} + u_{yy}$ and show that it is equal to zero:

$$\begin{aligned} u_{xx} + u_{yy} &= \frac{\partial}{\partial x}(u_x) + \frac{\partial}{\partial y}(u_y) = \frac{\partial}{\partial x}(v_y) + \frac{\partial}{\partial y}(-v_x) \quad (\text{since } u_x = v_y \text{ and } u_y = -v_x) \\ &= \frac{\partial}{\partial x}(v_y) - \frac{\partial}{\partial y}(v_x) = v_{yx} - v_{xy} = v_{yx} - v_{yx} \quad (\text{by the equality of mixed partials}) \\ &= 0. \end{aligned}$$

Therefore, u is a harmonic function. To show that v is a harmonic function, we compute $v_{xx} + v_{yy}$ and show that it is equal to zero:

$$\begin{aligned} v_{xx} + v_{yy} &= \frac{\partial}{\partial x}(v_x) + \frac{\partial}{\partial y}(v_y) = \frac{\partial}{\partial x}(-u_y) + \frac{\partial}{\partial y}(u_x) \quad (\text{since } u_x = v_y \text{ and } u_y = -v_x) \\ &= -\frac{\partial}{\partial x}(u_y) + \frac{\partial}{\partial y}(u_x) = -u_{yx} + u_{xy} = -u_{yx} + u_{yx} \quad (\text{by the equality of mixed partials}) \\ &= 0. \end{aligned}$$

Therefore, v is a harmonic function.

73. For $y \neq 0$,

$$\begin{aligned} \frac{\partial u}{\partial x} &= \frac{\partial}{\partial x} \left(z \tan^{-1} \frac{x}{y} \right) = z \cdot \frac{\partial}{\partial x} \left(z \tan^{-1} \frac{x}{y} \right) = z \cdot \frac{1}{1 + \left(\frac{x}{y} \right)^2} \cdot \frac{\partial}{\partial x} \left(\frac{x}{y} \right) \\ &= z \cdot \frac{1}{1 + \left(\frac{x}{y} \right)^2} \cdot \frac{1}{y} \cdot \frac{\partial}{\partial x}(x) = z \cdot \frac{1}{1 + \left(\frac{x}{y} \right)^2} \cdot \frac{1}{y} \cdot 1 = z \cdot \frac{y^2}{x^2 + y^2} \cdot \frac{1}{y} = \frac{yz}{x^2 + y^2} \\ \frac{\partial^2 u}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial u}{\partial x} \right) = \frac{\partial}{\partial x} \left(\frac{yz}{x^2 + y^2} \right) = yz \cdot \frac{\partial}{\partial x} ((x^2 + y^2)^{-1}) \\ &= yz \cdot (-1(x^2 + y^2)^{-2}) \cdot \frac{\partial}{\partial x}(x^2 + y^2) = -yz \cdot (x^2 + y^2)^{-2} \cdot (2x + 0) = \frac{-2xyz}{(x^2 + y^2)^2} \\ \frac{\partial u}{\partial y} &= \frac{\partial}{\partial y} \left(z \tan^{-1} \frac{x}{y} \right) = z \cdot \frac{1}{1 + \left(\frac{x}{y} \right)^2} \cdot \frac{\partial}{\partial y} \left(\frac{x}{y} \right) \\ &= z \cdot \frac{1}{1 + \left(\frac{x}{y} \right)^2} \cdot x \cdot \frac{\partial}{\partial y}(y^{-1}) = z \cdot \frac{1}{1 + \left(\frac{x}{y} \right)^2} \cdot x \cdot (-y^{-2}) = z \cdot \frac{y^2}{x^2 + y^2} \cdot \frac{-x}{y^2} = \frac{-xz}{x^2 + y^2} \\ \frac{\partial^2 u}{\partial y^2} &= \frac{\partial}{\partial y} \left(\frac{\partial u}{\partial y} \right) = \frac{\partial}{\partial y} \left(\frac{-xz}{x^2 + y^2} \right) = -xz \cdot \frac{\partial}{\partial y} ((x^2 + y^2)^{-1}) \\ &= -xz \cdot (-1(x^2 + y^2)^{-2}) \cdot \frac{\partial}{\partial y}(x^2 + y^2) = xz(x^2 + y^2)^{-2} \cdot (0 + 2y) = \frac{2xyz}{(x^2 + y^2)^2} \end{aligned}$$

$$\begin{aligned}\frac{\partial u}{\partial z} &= \frac{\partial}{\partial z} \left(z \tan^{-1} \frac{x}{y} \right) = \tan^{-1} \frac{x}{y} \cdot \frac{\partial}{\partial z} (z) \\ &= \tan^{-1} \frac{x}{y} \cdot 1 = \tan^{-1} \frac{x}{y}\end{aligned}$$

$$\frac{\partial^2 u}{\partial z^2} = \frac{\partial}{\partial z} \left(\frac{\partial u}{\partial z} \right) = \frac{\partial}{\partial z} \left(\tan^{-1} \frac{x}{y} \right) = 0$$

The last derivative is zero because, when we compute a partial derivative with respect to z , the variables x and y are treated as constants, which means that the entire expression $\tan^{-1} \frac{x}{y}$ is treated as a constant.

Adding up the three second-order partial derivatives that we computed, we get:

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = \frac{-2xyz}{(x^2 + y^2)^2} + \frac{2xyz}{(x^2 + y^2)^2} + 0 = \frac{-2xyz + 2xyz}{(x^2 + y^2)^2} = \frac{0}{(x^2 + y^2)^2} = 0,$$

which means that the function $u = z \tan^{-1} \frac{x}{y}$ satisfies the equation $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$.

74.

$$\begin{aligned}f_x(x, y, z) &= \frac{\partial}{\partial x} \left((x^2 + y^2 + z^2)^{-1/2} \right) = -\frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-3/2} \cdot \frac{\partial}{\partial x} (x^2 + y^2 + z^2) \\ &= -\frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-3/2} \cdot (2x + 0 + 0) = \frac{-x}{(x^2 + y^2 + z^2)^{3/2}}\end{aligned}$$

$$\begin{aligned}f_{xx}(x, y, z) &= \frac{\partial}{\partial x} (f_x(x, y, z)) = \frac{\partial}{\partial x} \left(-x(x^2 + y^2 + z^2)^{-3/2} \right) \\ &= \frac{\left(\frac{\partial}{\partial x} (-x) \right) (x^2 + y^2 + z^2)^{3/2} - (-x) \left(\frac{\partial}{\partial x} ((x^2 + y^2 + z^2)^{3/2}) \right)}{\left((x^2 + y^2 + z^2)^{3/2} \right)^2} \\ &= \frac{(-1) \cdot (x^2 + y^2 + z^2)^{3/2} - (-x) \cdot \frac{3}{2} \cdot (x^2 + y^2 + z^2)^{1/2} \left(\frac{\partial}{\partial x} (x^2 + y^2 + z^2) \right)}{(x^2 + y^2 + z^2)^3} \\ &= \frac{(-1) \cdot (x^2 + y^2 + z^2)^{3/2} - (-x) \cdot \frac{3}{2} \cdot (x^2 + y^2 + z^2)^{1/2} \cdot (2x + 0 + 0)}{(x^2 + y^2 + z^2)^3} \\ &= \frac{-(x^2 + y^2 + z^2)^{3/2} + 3x^2(x^2 + y^2 + z^2)^{1/2}}{(x^2 + y^2 + z^2)^3} \\ &= (x^2 + y^2 + z^2)^{1/2} \cdot \frac{-(x^2 + y^2 + z^2) + 3x^2}{(x^2 + y^2 + z^2)^3} = \frac{2x^2 - y^2 - z^2}{(x^2 + y^2 + z^2)^{5/2}}\end{aligned}$$

$$\begin{aligned}f_y(x, y) &= \frac{\partial}{\partial y} \left((x^2 + y^2 + z^2)^{-1/2} \right) = -\frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-3/2} \cdot \frac{\partial}{\partial y} (x^2 + y^2 + z^2) \\ &= -\frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-3/2} \cdot (0 + 2y + 0) = \frac{-y}{(x^2 + y^2 + z^2)^{3/2}}\end{aligned}$$

$$\begin{aligned}
f_{yy}(x, y, z) &= \frac{\partial}{\partial y} (f_y(x, y, z)) = \frac{\partial}{\partial y} \left(-y(x^2 + y^2 + z^2)^{-3/2} \right) \\
&= \frac{\left(\frac{\partial}{\partial y} (-y) \right) (x^2 + y^2 + z^2)^{3/2} - (-y) \left(\frac{\partial}{\partial y} ((x^2 + y^2 + z^2)^{3/2}) \right)}{\left((x^2 + y^2 + z^2)^{3/2} \right)^2} \\
&= \frac{(-1) \cdot (x^2 + y^2 + z^2)^{3/2} - (-y) \cdot \frac{3}{2} \cdot (x^2 + y^2 + z^2)^{1/2} \left(\frac{\partial}{\partial y} (x^2 + y^2 + z^2) \right)}{(x^2 + y^2 + z^2)^3} \\
&= \frac{(-1) \cdot (x^2 + y^2 + z^2)^{3/2} - (-y) \cdot \frac{3}{2} \cdot (x^2 + y^2 + z^2)^{1/2} \cdot (0 + 2y + 0)}{(x^2 + y^2 + z^2)^3} \\
&= \frac{-(x^2 + y^2 + z^2)^{3/2} + 3y^2(x^2 + y^2 + z^2)^{1/2}}{(x^2 + y^2 + z^2)^3} \\
&= (x^2 + y^2 + z^2)^{1/2} \cdot \frac{-(x^2 + y^2 + z^2) + 3y^2}{(x^2 + y^2 + z^2)^3} = \frac{-x^2 + 2y^2 - z^2}{(x^2 + y^2 + z^2)^{5/2}}
\end{aligned}$$

$$\begin{aligned}
f_z(x, y, z) &= \frac{\partial}{\partial z} \left((x^2 + y^2 + z^2)^{-1/2} \right) = -\frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-3/2} \cdot \frac{\partial}{\partial z} (x^2 + y^2 + z^2) \\
&= -\frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-3/2} \cdot (0 + 0 + 2z) = \frac{-z}{(x^2 + y^2 + z^2)^{3/2}}
\end{aligned}$$

$$\begin{aligned}
f_{zz}(x, y, z) &= \frac{\partial}{\partial z} (f_z(x, y, z)) = \frac{\partial}{\partial z} \left(-z(x^2 + y^2 + z^2)^{-3/2} \right) \\
&= \frac{\left(\frac{\partial}{\partial z} (-z) \right) (x^2 + y^2 + z^2)^{3/2} - (-z) \left(\frac{\partial}{\partial z} ((x^2 + y^2 + z^2)^{3/2}) \right)}{\left((x^2 + y^2 + z^2)^{3/2} \right)^2} \\
&= \frac{(-1) \cdot (x^2 + y^2 + z^2)^{3/2} - (-z) \cdot \frac{3}{2} \cdot (x^2 + y^2 + z^2)^{1/2} \left(\frac{\partial}{\partial z} (x^2 + y^2 + z^2) \right)}{(x^2 + y^2 + z^2)^3} \\
&= \frac{(-1) \cdot (x^2 + y^2 + z^2)^{3/2} - (-z) \cdot \frac{3}{2} \cdot (x^2 + y^2 + z^2)^{1/2} \cdot (0 + 0 + 2z)}{(x^2 + y^2 + z^2)^3} \\
&= \frac{-(x^2 + y^2 + z^2)^{3/2} + 3z^2(x^2 + y^2 + z^2)^{1/2}}{(x^2 + y^2 + z^2)^3} \\
&= (x^2 + y^2 + z^2)^{1/2} \cdot \frac{-(x^2 + y^2 + z^2) + 3z^2}{(x^2 + y^2 + z^2)^3} = \frac{-x^2 - y^2 + 2z^2}{(x^2 + y^2 + z^2)^{5/2}}
\end{aligned}$$

Adding up the three second-order partial derivatives that we computed, we get

$$\begin{aligned}
f_{xx}(x, y, z) + f_{yy}(x, y, z) + f_{zz}(x, y, z) &= \frac{2x^2 - y^2 - z^2}{(x^2 + y^2 + z^2)^{5/2}} + \frac{-x^2 + 2y^2 - z^2}{(x^2 + y^2 + z^2)^{5/2}} + \frac{-x^2 - y^2 + 2z^2}{(x^2 + y^2 + z^2)^{5/2}} \\
&= \frac{2x^2 - y^2 - z^2 - x^2 + 2y^2 - z^2 - x^2 - y^2 + 2z^2}{(x^2 + y^2 + z^2)^{5/2}} \\
&= \frac{0}{(x^2 + y^2 + z^2)^{5/2}} = 0.
\end{aligned}$$

Therefore, $f(x, y, z) = (x^2 + y^2 + z^2)^{-1/2}$ satisfies the three-dimensional Laplace equation

$$f_{xx} + f_{yy} + f_{zz} = 0.$$

75. (a) If $(x, y) \neq (0, 0)$, then

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} \left(\frac{xy^3}{x^2 + y^2} \right) = y^3 \cdot \frac{\partial}{\partial x} \left(\frac{x}{x^2 + y^2} \right) = y^3 \cdot \frac{\left(\frac{\partial}{\partial x} (x) \right) (x^2 + y^2) - x \left(\frac{\partial}{\partial x} (x^2 + y^2) \right)}{(x^2 + y^2)^2} \\ &= y^3 \cdot \frac{1 \cdot (x^2 + y^2) - x \cdot (2x)}{(x^2 + y^2)^2} = y^3 \cdot \frac{x^2 + y^2 - 2x^2}{(x^2 + y^2)^2} = y^3 \cdot \frac{-x^2 + y^2}{(x^2 + y^2)^2} \end{aligned}$$

and

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} \left(\frac{xy^3}{x^2 + y^2} \right) = x \cdot \frac{\partial}{\partial y} \left(\frac{y^3}{x^2 + y^2} \right) = x \cdot \frac{\left(\frac{\partial}{\partial y} (y^3) \right) (x^2 + y^2) - y^3 \left(\frac{\partial}{\partial y} (x^2 + y^2) \right)}{(x^2 + y^2)^2} \\ &= x \cdot \frac{3y^2 \cdot (x^2 + y^2) - y^3 \cdot (2y)}{(x^2 + y^2)^2} = x \cdot \frac{3x^2y^2 + 3y^4 - 2y^4}{(x^2 + y^2)^2} = x \cdot \frac{3x^2y^2 + y^4}{(x^2 + y^2)^2} \\ &= xy^2 \cdot \frac{3x^2 + y^2}{(x^2 + y^2)^2} \end{aligned}$$

Now we need to compute the partial derivatives at $(0, 0)$. We will use the definition of a partial derivative.

$$\begin{aligned} f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x) \cdot 0}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} = \lim_{\Delta x \rightarrow 0} 0 = 0 \end{aligned}$$

$$\begin{aligned} f_y(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\frac{0 \cdot (\Delta y)^3}{0 + (\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{0}{\Delta y} = \lim_{\Delta y \rightarrow 0} 0 = 0 \end{aligned}$$

$f_x(x, y) = \begin{cases} \frac{-y^3(x^2 - y^2)}{(x^2 + y^2)^2} & (x, y) \neq (0, 0) \\ 0 & (x, y) = (0, 0) \end{cases}$	$f_y(x, y) = \begin{cases} \frac{xy^2(3x^2 + y^2)}{(x^2 + y^2)^2} & (x, y) \neq (0, 0) \\ 0 & (x, y) = (0, 0) \end{cases}$
---	--

(b) We will use the definition of a partial derivative to compute $f_{xy}(0, 0)$ and $f_{yx}(0, 0)$.

$$\begin{aligned} f_{xy}(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f_x(0, 0 + \Delta y) - f_x(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f_x(0, \Delta y) - f_x(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{(\Delta y)^3 \left(\frac{0 + (\Delta y)^2}{(0 + (\Delta y)^2)^2} \right) - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{\frac{(\Delta y)^5}{(\Delta y)^4}}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{\Delta y}{\Delta y} = \lim_{\Delta y \rightarrow 0} 1 = 1 \end{aligned}$$

$$\begin{aligned} f_{yx}(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f_y(0 + \Delta x, 0) - f_y(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f_y(\Delta x, 0) - f_y(0, 0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{(\Delta x) \cdot 0 \cdot \frac{3(\Delta x)^2 + 0}{((\Delta x)^2 + 0)^2} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} = \lim_{\Delta x \rightarrow 0} 0 = 0 \end{aligned}$$

Since $f_{xy}(0, 0) = 1$ and $f_{yx}(0, 0) = 0$, we conclude that $f_{xy}(0, 0) \neq f_{yx}(0, 0)$.

76. (a) First, let us compute $f_x(x, y)$. If $(x, y) \neq (0, 0)$, then

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} \left(\frac{xy(x^2 - y^2)}{x^2 + y^2} \right) = y \cdot \frac{\partial}{\partial x} \left(\frac{x^3 - xy^2}{x^2 + y^2} \right) \\ &= y \cdot \frac{\left(\frac{\partial}{\partial x} (x^3 - xy^2) \right) (x^2 + y^2) - (x^3 - xy^2) \left(\frac{\partial}{\partial x} (x^2 + y^2) \right)}{(x^2 + y^2)^2} \\ &= y \cdot \frac{(3x^2 - y^2)(x^2 + y^2) - (x^3 - xy^2)(2x)}{(x^2 + y^2)^2} \\ &= y \cdot \frac{3x^4 + 3x^2y^2 - x^2y^2 - y^4 - 2x^4 + 2x^2y^2}{(x^2 + y^2)^2} = y \cdot \frac{x^4 + 4x^2y^2 - y^4}{(x^2 + y^2)^2} \end{aligned}$$

In particular, if we let $x = 0$, then for all $y \neq 0$ we have

$$f_x(0, y) = y \cdot \frac{0 + 0 - y^4}{(0 + y^2)^2} = y \cdot \frac{-y^4}{y^4} = -y.$$

So the formula $f_x(0, y) = -y$ is correct for all y , except perhaps $y = 0$. Now we need to compute $f_x(0, 0)$. We will use the definition of a partial derivative. In order for our formula $f_x(0, y) = -y$ to be correct for $y = 0$, $f_x(0, 0)$ should be 0.

$$\begin{aligned} f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x) \cdot 0 \cdot ((\Delta x)^2 - 0)}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} = \lim_{\Delta x \rightarrow 0} 0 = 0 \end{aligned}$$

So our formula $f_x(0, y) = -y$ is correct even when $y = 0$.

(b) Now, let us compute $f_y(x, y)$. If $(x, y) \neq (0, 0)$, then

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} \left(\frac{xy(x^2 - y^2)}{x^2 + y^2} \right) = x \cdot \frac{\partial}{\partial y} \left(\frac{x^2y - y^3}{x^2 + y^2} \right) \\ &= x \cdot \frac{\left(\frac{\partial}{\partial y} (x^2y - y^3) \right) (x^2 + y^2) - (x^2y - y^3) \left(\frac{\partial}{\partial y} (x^2 + y^2) \right)}{(x^2 + y^2)^2} \\ &= x \cdot \frac{(x^2 - 3y^2)(x^2 + y^2) - (x^2y - y^3)(2y)}{(x^2 + y^2)^2} \\ &= x \cdot \frac{x^4 + x^2y^2 - 3x^2y^2 - 3y^4 - 2x^2y^2 + 2y^4}{(x^2 + y^2)^2} = x \cdot \frac{x^4 - 4x^2y^2 + 2xy^3 - y^4}{(x^2 + y^2)^2} \end{aligned}$$

In particular, if we let $y = 0$, then for all $x \neq 0$ we have

$$f_y(x, 0) = x \cdot \frac{x^4 - 0 + 0 - 0}{(x^2 + 0)^2} = x \cdot \frac{x^4}{x^4} = x.$$

So the formula $f_y(x, 0) = x$ is correct for all x , except perhaps $x = 0$. Now we need to compute $f_y(0, 0)$. We will use the definition of a partial derivative. In order for our formula $f_y(x, 0) = x$ to be correct for $x = 0$, $f_y(0, 0)$ should be 0.

$$\begin{aligned} f_y(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\frac{0 \cdot (\Delta y) \cdot (0 - (\Delta y)^2)}{0 + (\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{0}{\Delta y} = \lim_{\Delta y \rightarrow 0} 0 = 0 \end{aligned}$$

So our formula $f_y(x, 0) = x$ is correct even when $x = 0$.

(c) Using the definition of a partial derivative,

$$\begin{aligned} f_{xy}(0,0) &= \lim_{\Delta y \rightarrow 0} \frac{f_x(0,0+\Delta y) - f_x(0,0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f_x(0,\Delta y) - f_x(0,0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{-(\Delta y) - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{-\Delta y}{\Delta y} = \lim_{\Delta y \rightarrow 0} -1 = -1. \end{aligned}$$

(d) Using the definition of a partial derivative,

$$\begin{aligned} f_{yx}(0,0) &= \lim_{\Delta x \rightarrow 0} \frac{f_y(0+\Delta x,0) - f_y(0,0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f_y(\Delta x,0) - f_y(0,0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\Delta x - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\Delta x}{\Delta x} = \lim_{\Delta x \rightarrow 0} 1 = 1. \end{aligned}$$

77. If there is such a function f , then it must be the case that:

$$\begin{aligned} f_{xy}(x,y) &= \frac{\partial}{\partial y} (f_x(x,y)) = \frac{\partial}{\partial y} (3x - y) = \frac{\partial}{\partial y} (3x) - \frac{\partial}{\partial y} (y) = 0 - 1 = -1 \\ f_{yx}(x,y) &= \frac{\partial}{\partial x} (f_y(x,y)) = \frac{\partial}{\partial x} (x - 3y) = \frac{\partial}{\partial x} (x) - \frac{\partial}{\partial x} (3y) = 1 - 0 = 1. \end{aligned}$$

So, the partial derivatives f_x, f_y, f_{xy}, f_{yx} all exist (at every point in $\mathbb{R}^2$), and f_{xy} and f_{yx} are constant functions, so they are continuous at every point in $\mathbb{R}^2$. Therefore, the conditions of the Equality of Mixed Partials Theorem (Clairaut's Theorem) are satisfied, and it must be the case that f_{xy} and f_{yx} are equal at every point in $\mathbb{R}^2$.

However, $f_{xy}(x,y) = -1$, and $f_{yx}(x,y) = 1$, so the two are not equal. This means that such a function f cannot exist. Therefore, no, you should not believe it.

78. If there is such a function $z = f(x,y)$, then it must be the case that:

$$\begin{aligned} f_{xy}(x,y) &= \frac{\partial}{\partial y} (f_x(x,y)) = \frac{\partial}{\partial y} (2x - y) = \frac{\partial}{\partial y} (2x) - \frac{\partial}{\partial y} (y) = 0 - 1 = -1 \\ f_{yx}(x,y) &= \frac{\partial}{\partial x} (f_y(x,y)) = \frac{\partial}{\partial x} (x - 2y) = \frac{\partial}{\partial x} (x) - \frac{\partial}{\partial x} (2y) = 1 - 0 = 1. \end{aligned}$$

So, the partial derivatives f_x, f_y, f_{xy}, f_{yx} all exist (at every point in $\mathbb{R}^2$), and f_{xy} and f_{yx} are constant functions, so they are continuous at every point in $\mathbb{R}^2$. Therefore, the conditions of the Equality of Mixed Partials Theorem (Clairaut's Theorem) are satisfied, and it must be the case that f_{xy} and f_{yx} are equal at every point in $\mathbb{R}^2$.

However, $f_{xy}(x,y) = -1$, and $f_{yx}(x,y) = 1$, so the two are not equal. This means that such a function f cannot exist.

79. Let us define $f(x,y)$ to be $\sqrt{x^2 + y^2}$, so that $z = f(x,y) = \sqrt{x^2 + y^2}$. Using the definition of a partial derivative,

$$\begin{aligned} f_x(0,0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0+\Delta x,0) - f(0,0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x,0) - f(0,0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\sqrt{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\sqrt{(\Delta x)^2}}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{|\Delta x|}{\Delta x}. \end{aligned}$$

We investigate the one-sided limits:

$$\begin{aligned}\lim_{\Delta x \rightarrow 0^+} \frac{|\Delta x|}{\Delta x} &= \lim_{\Delta x \rightarrow 0^+} \frac{\Delta x}{\Delta x} = \lim_{\Delta x \rightarrow 0^+} 1 = 1 \\ \lim_{\Delta x \rightarrow 0^-} \frac{|\Delta x|}{\Delta x} &= \lim_{\Delta x \rightarrow 0^-} \frac{-\Delta x}{\Delta x} = \lim_{\Delta x \rightarrow 0^-} -1 = -1\end{aligned}$$

Since the one-sided limits are not equal, we conclude that $\lim_{\Delta x \rightarrow 0} \frac{|\Delta x|}{\Delta x}$ does not exist. Therefore, $f_x(0, 0)$ does not exist.

$$\begin{aligned}f_y(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\sqrt{0 + (\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{\sqrt{(\Delta y)^2}}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{|\Delta y|}{\Delta y}.\end{aligned}$$

We investigate the one-sided limits:

$$\begin{aligned}\lim_{\Delta y \rightarrow 0^+} \frac{|\Delta y|}{\Delta y} &= \lim_{\Delta y \rightarrow 0^+} \frac{\Delta y}{\Delta y} = \lim_{\Delta y \rightarrow 0^+} 1 = 1 \\ \lim_{\Delta y \rightarrow 0^-} \frac{|\Delta y|}{\Delta y} &= \lim_{\Delta y \rightarrow 0^-} \frac{-\Delta y}{\Delta y} = \lim_{\Delta y \rightarrow 0^-} -1 = -1\end{aligned}$$

Since the one-sided limits are not equal, we conclude that $\lim_{\Delta y \rightarrow 0} \frac{|\Delta y|}{\Delta y}$ does not exist. Therefore, $f_y(0, 0)$ does not exist. We conclude that the function $z = \sqrt{x^2 + y^2}$ does not have partial derivatives at $(0, 0)$. For the geometric reason why this should be so, answers will vary.

80.

$$\begin{aligned}f\left(1, -\frac{1}{3}\right) &= 4 \cdot 1^2 + 9 \cdot \left(-\frac{1}{3}\right)^2 - 12 = -7 \\ f_x(x, y) &= \frac{\partial}{\partial x} (4x^2 + 9y^2 - 12) = 4 \frac{\partial}{\partial x} (x^2) + 9 \frac{\partial}{\partial x} (y^2) - \frac{\partial}{\partial x} (12) = 4 \cdot 2x + 0 - 0 = 8x \\ f_x\left(1, -\frac{1}{3}\right) &= 8 \cdot 1 = 8 \\ f_y(x, y) &= \frac{\partial}{\partial y} (4x^2 + 9y^2 - 12) = 4 \frac{\partial}{\partial y} (x^2) + 9 \frac{\partial}{\partial y} (y^2) - \frac{\partial}{\partial y} (12) = 0 + 9 \cdot 2y - 0 = 18y \\ f_y\left(1, -\frac{1}{3}\right) &= 18 \cdot \left(-\frac{1}{3}\right) = -6\end{aligned}$$

These values can be interpreted as slopes of tangent lines. More specifically,

The slope of the tangent line to the curve of intersection of the surface $z = 4x^2 + 9y^2 - 12$ and the plane $y = -\frac{1}{3}$ at the point $(1, -\frac{1}{3}, -7)$ equals 8.

The slope of the tangent line to the curve of intersection of the surface $z = 4x^2 + 9y^2 - 12$ and the plane $x = 1$ at the point $(1, -\frac{1}{3}, -7)$ equals -6.

81.

$$\begin{aligned}f_x(x, y, z) &= \frac{\partial}{\partial x} (e^{x/y} + e^{y/z} + e^{z/x}) = \frac{\partial}{\partial x} (e^{x/y}) + \frac{\partial}{\partial x} (e^{y/z}) + \frac{\partial}{\partial x} (e^{z/x}) \\ &= e^{x/y} \cdot \frac{\partial}{\partial x} \left(\frac{x}{y}\right) + 0 + e^{z/x} \cdot \frac{\partial}{\partial x} \left(\frac{z}{x}\right) = e^{x/y} \cdot \frac{1}{y} \cdot \frac{\partial}{\partial x} (x) + 0 + e^{z/x} \cdot z \cdot \frac{\partial}{\partial x} (x^{-1}) \\ &= e^{x/y} \cdot \frac{1}{y} \cdot 1 + 0 + e^{z/x} \cdot z \cdot (-x^{-2}) = \frac{1}{y} \cdot e^{x/y} - \frac{z}{x^2} e^{z/x}\end{aligned}$$

$$\begin{aligned}
f_y(x, y, z) &= \frac{\partial}{\partial y} (e^{x/y} + e^{y/z} + e^{z/x}) = \frac{\partial}{\partial y} (e^{x/y}) + \frac{\partial}{\partial y} (e^{y/z}) + \frac{\partial}{\partial y} (e^{z/x}) \\
&= e^{x/y} \cdot \frac{\partial}{\partial y} \left(\frac{x}{y} \right) + e^{y/z} \cdot \frac{\partial}{\partial y} \left(\frac{y}{z} \right) + 0 = e^{x/y} \cdot x \cdot \frac{\partial}{\partial y} (y^{-1}) + e^{y/z} \cdot \frac{1}{z} \cdot \frac{\partial}{\partial y} (y) + 0 \\
&= e^{x/y} \cdot x \cdot (-y^{-2}) + e^{y/z} \cdot \frac{1}{z} \cdot 1 + 0 = -\frac{x}{y^2} \cdot e^{x/y} + \frac{1}{z} e^{y/z}
\end{aligned}$$

$$\begin{aligned}
f_z(x, y, z) &= \frac{\partial}{\partial z} (e^{x/y} + e^{y/z} + e^{z/x}) = \frac{\partial}{\partial z} (e^{x/y}) + \frac{\partial}{\partial z} (e^{y/z}) + \frac{\partial}{\partial z} (e^{z/x}) \\
&= 0 + e^{y/z} \cdot \frac{\partial}{\partial z} \left(\frac{y}{z} \right) + e^{z/x} \cdot \frac{\partial}{\partial z} \left(\frac{z}{x} \right) = 0 + e^{y/z} \cdot y \cdot \frac{\partial}{\partial z} (z^{-1}) + e^{z/x} \cdot \frac{1}{x} \cdot \frac{\partial}{\partial z} (z) \\
&= 0 + e^{y/z} \cdot y \cdot (-z^{-2}) + e^{z/x} \cdot \frac{1}{x} \cdot 1 + 0 = -\frac{y}{z^2} \cdot e^{y/z} + \frac{1}{x} e^{z/x}
\end{aligned}$$

It follows that

$$\begin{aligned}
&xf_x(x, y, z) + yf_y(x, y, z) + zf_z(x, y, z) \\
&= x \left(\frac{1}{y} \cdot e^{x/y} - \frac{z}{x^2} e^{z/x} \right) + y \left(-\frac{x}{y^2} \cdot e^{x/y} + \frac{1}{z} e^{y/z} \right) + z \left(-\frac{y}{z^2} \cdot e^{y/z} + \frac{1}{x} e^{z/x} \right) \\
&= \frac{x}{y} \cdot e^{x/y} - \frac{z}{x} e^{z/x} - \frac{x}{y} e^{x/y} + \frac{y}{z} e^{y/z} - \frac{y}{z} e^{y/z} + \frac{z}{x} e^{z/x} = 0.
\end{aligned}$$

Therefore, $f(x, y, z) = e^{x/y} + e^{y/z} + e^{z/x}$ satisfies the equation

$$xf_x + yf_y + zf_z = 0.$$

82.

$$\begin{aligned}
f_x(t, x, y) &= \frac{\partial}{\partial x} (e^{at} \sin(bx) \cos(cy)) = e^{at} \cos(cy) \frac{\partial}{\partial x} (\sin(bx)) \\
&= e^{at} \cos(cy) \cos(bx) \cdot \frac{\partial}{\partial x} (bx) = e^{at} \cos(cy) \cos(bx) \cdot b = be^{at} \cos(bx) \cos(cy)
\end{aligned}$$

$$\begin{aligned}
f_{xx}(t, x, y) &= \frac{\partial}{\partial x} (f_x(t, x, y)) = \frac{\partial}{\partial x} (be^{at} \cos(bx) \cos(cy)) = be^{at} \cos(cy) \frac{\partial}{\partial x} (\cos(bx)) \\
&= be^{at} \cos(cy) (-\sin(bx)) \cdot \frac{\partial}{\partial x} (bx) = be^{at} \cos(cy) (-\sin(bx)) \cdot b = -b^2 e^{at} \sin(bx) \cos(cy)
\end{aligned}$$

$$\begin{aligned}
f_y(t, x, y) &= \frac{\partial}{\partial y} (e^{at} \sin(bx) \cos(cy)) = e^{at} \sin(bx) \frac{\partial}{\partial y} (\cos(cy)) \\
&= e^{at} \sin(bx) (-\sin(cy)) \cdot \frac{\partial}{\partial y} (cy) = e^{at} \sin(bx) (-\sin(cy)) \cdot c = -ce^{at} \sin(bx) \sin(cy)
\end{aligned}$$

$$\begin{aligned}
f_{yy}(t, x, y) &= \frac{\partial}{\partial y} (f_y(t, x, y)) = \frac{\partial}{\partial y} (-ce^{at} \sin(bx) \sin(cy)) = -ce^{at} \sin(bx) \frac{\partial}{\partial y} (\sin(cy)) \\
&= -ce^{at} \sin(bx) \cos(cy) \cdot \frac{\partial}{\partial y} (cy) = -ce^{at} \sin(bx) \cos(cy) \cdot c = -c^2 e^{at} \sin(bx) \cos(cy)
\end{aligned}$$

$$\begin{aligned}
f_t(t, x, y) &= \frac{\partial}{\partial t} (e^{at} \sin(bx) \cos(cy)) = \sin(bx) \cos(cy) \frac{\partial}{\partial t} (e^{at}) \\
&= \sin(bx) \cos(cy) e^{at} \cdot \frac{\partial}{\partial t} (at) = \sin(bx) \cos(cy) e^{at} \cdot a = ae^{at} \sin(bx) \cos(cy)
\end{aligned}$$

So, the equation $f_t = f_{xx} + f_{yy}$ will be satisfied when

$$ae^{at} \sin(bx) \cos(cy) = -b^2 e^{at} \sin(bx) \cos(cy) - c^2 e^{at} \sin(bx) \cos(cy),$$

which after factoring becomes

$$ae^{at} \sin(bx) \cos(cy) = (-b^2 - c^2) (e^{at} \sin(bx) \cos(cy)).$$

Dividing both sides by $e^{at} \sin(bx) \cos(cy)$ gives us the desired expression: $\boxed{a = -b^2 - c^2}$. (Note that though there are specific values of x and y that will make the quantity $e^{at} \sin(bx) \cos(cy) = 0$, and which will satisfy the equation before we divide by this quantity, we are seeking a, b , and c values which satisfy $f_t = f_{xx} + f_{yy}$ for *all* values of x, y .)

83.

$$f_x(x, t) = \frac{\partial}{\partial x} (\cos(x + ct)) = -\sin(x + ct) \frac{\partial}{\partial x} (x + ct) = -\sin(x + ct) \cdot 1 = -\sin(x + ct)$$

$$\begin{aligned} f_{xx}(x, t) &= \frac{\partial}{\partial x} (f_x(x, t)) \\ &= \frac{\partial}{\partial x} (-\sin(x + ct)) = -\cos(x + ct) \frac{\partial}{\partial x} (x + ct) = -\cos(x + ct) \cdot 1 = -\cos(x + ct) \end{aligned}$$

$$f_t(x, t) = \frac{\partial}{\partial t} (\cos(x + ct)) = -\sin(x + ct) \frac{\partial}{\partial t} (x + ct) = -\sin(x + ct) \cdot c = -c \sin(x + ct)$$

$$\begin{aligned} f_{tt}(x, t) &= \frac{\partial}{\partial t} (f_t(x, t)) \\ &= \frac{\partial}{\partial t} (-c \sin(x + ct)) = -c \cos(x + ct) \frac{\partial}{\partial t} (x + ct) = -c \cos(x + ct) \cdot c = -c^2 \cos(x + ct) \end{aligned}$$

So,

$$c^2 f_{xx}(x, t) = c^2 (-\cos(x + ct)) = -c^2 \cos(x + ct) = f_{tt}(x, t).$$

Therefore, $f(x, t) = \cos(x + ct)$ does satisfy the equation $f_{tt} = c^2 f_{xx}$.

84.

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} \left(\int_x^y \ln(\cos \sqrt{t}) dt \right) \\ &= \frac{\partial}{\partial x} \left(- \int_y^x \ln(\cos \sqrt{t}) dt \right) = - \frac{\partial}{\partial x} \left(\int_y^x \ln(\cos \sqrt{t}) dt \right) = -\ln(\cos \sqrt{x}), \end{aligned}$$

by the Fundamental Theorem of Calculus, Part 1 (see Section 5.3, page 362).

So $\boxed{f_x(x, y) = -\ln(\cos \sqrt{x})}$.

$$f_y(x, y) = \frac{\partial}{\partial y} \left(\int_x^y \ln(\cos \sqrt{t}) dt \right) = \ln \cos \sqrt{y},$$

again, by the Fundamental Theorem of Calculus, Part 1 (see Section 5.3, page 362).

So $\boxed{f_y(x, y) = \ln(\cos \sqrt{y})}$.

85. We solve for a :

$$a = \pm \sqrt{b^2 + c^2 - 2bc \cos A}.$$

However, since a is the length of a side of a triangle, it cannot be negative. So, we reject the negative root, and we have

$$a = \sqrt{b^2 + c^2 - 2bc \cos A} = (b^2 + c^2 - 2bc \cos A)^{1/2}.$$

(Note that $b^2 + c^2 - 2bc \cos A \neq 0$ since if it did, side length a would be 0.)

$$\begin{aligned} \frac{\partial a}{\partial b} &= \frac{\partial}{\partial b} \left((b^2 + c^2 - 2bc \cos A)^{1/2} \right) = \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \frac{\partial}{\partial b} (b^2 + c^2 - 2bc \cos A) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \frac{\partial}{\partial b} (b^2 + c^2 - 2bc \cos A) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \left(\frac{\partial}{\partial b} (b^2) + \frac{\partial}{\partial b} (c^2) - 2c \cos A \frac{\partial}{\partial b} (b) \right) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot (2b + 0 - 2c \cos A \cdot 1) \\ &= \frac{2b - 2c \cos A}{2\sqrt{b^2 + c^2 - 2bc \cos A}} = \frac{b - c \cos A}{\sqrt{b^2 + c^2 - 2bc \cos A}} \end{aligned}$$

$$\boxed{\frac{\partial a}{\partial b} = \frac{b - c \cos A}{\sqrt{b^2 + c^2 - 2bc \cos A}}}$$

$$\begin{aligned} \frac{\partial a}{\partial c} &= \frac{\partial}{\partial c} \left((b^2 + c^2 - 2bc \cos A)^{1/2} \right) = \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \frac{\partial}{\partial c} (b^2 + c^2 - 2bc \cos A) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \frac{\partial}{\partial c} (b^2 + c^2 - 2bc \cos A) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \left(\frac{\partial}{\partial c} (b^2) + \frac{\partial}{\partial c} (c^2) - 2b \cos A \frac{\partial}{\partial c} (c) \right) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot (0 + 2c - 2b \cos A \cdot 1) \\ &= \frac{2c - 2b \cos A}{2\sqrt{b^2 + c^2 - 2bc \cos A}} = \frac{c - b \cos A}{\sqrt{b^2 + c^2 - 2bc \cos A}} \end{aligned}$$

$$\boxed{\frac{\partial a}{\partial c} = \frac{c - b \cos A}{\sqrt{b^2 + c^2 - 2bc \cos A}}}$$

$$\begin{aligned} \frac{\partial a}{\partial A} &= \frac{\partial}{\partial A} \left((b^2 + c^2 - 2bc \cos A)^{1/2} \right) = \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \frac{\partial}{\partial A} (b^2 + c^2 - 2bc \cos A) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \frac{\partial}{\partial A} (b^2 + c^2 - 2bc \cos A) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot \left(\frac{\partial}{\partial A} (b^2) + \frac{\partial}{\partial A} (c^2) - 2bc \frac{\partial}{\partial A} (\cos A) \right) \\ &= \frac{1}{2} \cdot (b^2 + c^2 - 2bc \cos A)^{-1/2} \cdot (0 + 0 - 2bc(-\sin A)) \\ &= \frac{2bc \sin A}{2\sqrt{b^2 + c^2 - 2bc \cos A}} = \frac{bc \sin A}{\sqrt{b^2 + c^2 - 2bc \cos A}} \end{aligned}$$

$$\boxed{\frac{\partial a}{\partial A} = \frac{bc \sin A}{\sqrt{b^2 + c^2 - 2bc \cos A}}}$$

86.

$$\begin{aligned}\frac{\partial x}{\partial r} &= \frac{\partial}{\partial r} (r \cos \theta) = \cos \theta \cdot \frac{\partial}{\partial r} (r) = \cos \theta \cdot 1 = \cos \theta \\ \frac{\partial x}{\partial \theta} &= \frac{\partial}{\partial \theta} (r \cos \theta) = r \cdot \frac{\partial}{\partial \theta} (\cos \theta) = r \cdot (-\sin \theta) = -r \sin \theta \\ \frac{\partial y}{\partial r} &= \frac{\partial}{\partial r} (r \sin \theta) = \sin \theta \cdot \frac{\partial}{\partial r} (r) = \sin \theta \cdot 1 = \sin \theta \\ \frac{\partial y}{\partial \theta} &= \frac{\partial}{\partial \theta} (r \sin \theta) = r \cdot \frac{\partial}{\partial \theta} (\sin \theta) = r \cos \theta\end{aligned}$$

So,

$$\begin{aligned}\begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{vmatrix} &= \frac{\partial x}{\partial r} \cdot \frac{\partial y}{\partial \theta} - \frac{\partial x}{\partial \theta} \frac{\partial y}{\partial r} \\ &= (\cos \theta)(r \cos \theta) - (-r \sin \theta)(\sin \theta) = r \cos^2 \theta + r \sin^2 \theta = r(\cos^2 \theta + \sin^2 \theta) = r \cdot 1 = r.\end{aligned}$$

Next, since $r = \sqrt{x^2 + y^2}$ and $\theta = \tan^{-1} \left(\frac{y}{x} \right)$, we have (for $x \neq 0$):

$$\begin{aligned}\frac{\partial r}{\partial x} &= \frac{\partial}{\partial x} \left((x^2 + y^2)^{1/2} \right) = \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot \frac{\partial}{\partial x} (x^2 + y^2) \\ &= \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot 2x = \frac{x}{\sqrt{x^2 + y^2}} = \frac{x}{r} \\ \frac{\partial r}{\partial y} &= \frac{\partial}{\partial y} \left((x^2 + y^2)^{1/2} \right) = \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot \frac{\partial}{\partial y} (x^2 + y^2) \\ &= \frac{1}{2} \cdot (x^2 + y^2)^{-1/2} \cdot 2y = \frac{y}{\sqrt{x^2 + y^2}} = \frac{y}{r} \\ \frac{\partial \theta}{\partial x} &= \frac{\partial}{\partial x} \left(\tan^{-1} \frac{y}{x} \right) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{\partial}{\partial x} \left(\frac{y}{x} \right) \\ &= \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot y \cdot \frac{\partial}{\partial x} (x^{-1}) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot y \cdot (-x^{-2}) = \frac{x^2}{x^2 + y^2} \cdot \frac{-y}{x^2} = \frac{-y}{x^2 + y^2} = \frac{-y}{r^2} \\ \frac{\partial \theta}{\partial y} &= \frac{\partial}{\partial y} \left(\tan^{-1} \frac{y}{x} \right) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{\partial}{\partial y} \left(\frac{y}{x} \right) \\ &= \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{1}{x} \cdot \frac{\partial}{\partial y} (y) = \frac{1}{1 + \left(\frac{y}{x} \right)^2} \cdot \frac{1}{x} \cdot 1 = \frac{x^2}{x^2 + y^2} \cdot \frac{1}{x} = \frac{x}{x^2 + y^2} = \frac{x}{r^2}\end{aligned}$$

So,

$$\begin{aligned}\begin{vmatrix} \frac{\partial r}{\partial x} & \frac{\partial r}{\partial y} \\ \frac{\partial \theta}{\partial x} & \frac{\partial \theta}{\partial y} \end{vmatrix} &= \frac{\partial r}{\partial x} \cdot \frac{\partial \theta}{\partial y} - \frac{\partial r}{\partial y} \cdot \frac{\partial \theta}{\partial x} = \left(\frac{x}{r} \right) \left(\frac{x}{r^2} \right) - \left(\frac{y}{r} \right) \left(\frac{-y}{r^2} \right) = \frac{x^2}{r^3} + \frac{y^2}{r^3} = \frac{x^2 + y^2}{r^3} = \frac{r^2}{r^3} = \frac{1}{r}.\end{aligned}$$

Challenge Problems

87.

$$f_x(x, y) = \frac{\partial}{\partial x} (x^y), \text{ so } \boxed{f_x(x, y) = x^{y-1}y} \text{ (using the Power Rule).}$$

$$f_y(x, y) = \frac{\partial}{\partial y} (x^y), \text{ so } \boxed{f_y(x, y) = x^y \ln x}.$$

In the last calculation, we used the rule for the derivative of an exponential function, from page 202.

88. For f_x , we use logarithmic differentiation (see page 225). We start by taking the natural logarithm of each side:

$$\ln f(x, y) = \ln x^{2x+3y}$$

$$\ln f(x, y) = (2x + 3y) \cdot \ln x \text{ (using the properties of logarithms)}$$

and then we use implicit differentiation (we take the derivative of each side with respect to x , keeping y constant):

$$\begin{aligned} \frac{\partial}{\partial x} (\ln f(x, y)) &= \frac{\partial}{\partial x} ((2x + 3y) \cdot \ln x) \\ \frac{1}{f(x, y)} \frac{\partial}{\partial x} (f(x, y)) &= \left(\frac{\partial}{\partial x} (2x + 3y) \right) \cdot \ln x + (2x + 3y) \cdot \frac{\partial}{\partial x} (\ln x) \\ \frac{1}{f(x, y)} f_x(x, y) &= 2 \cdot \ln x + (2x + 3y) \cdot \frac{1}{x}. \end{aligned}$$

Multiplying both sides by $f(x, y)$, we get

$$f_x(x, y) = f(x, y) \left(2 \cdot \ln x + (2x + 3y) \cdot \frac{1}{x} \right) = x^{2x+3y} \left(2 \cdot \ln x + (2x + 3y) \cdot \frac{1}{x} \right).$$

$$\boxed{f_x(x, y) = 2 \ln x (x^{2x+3y}) + (2x + 3y) x^{2x+3y-1}}.$$

For f_y , we observe that $f(x, y) = x^{2x+3y} = x^{2x} \cdot x^{3y}$, so

$$f_y(x, y) = \frac{\partial}{\partial y} (x^{2x} \cdot x^{3y}) = x^{2x} \frac{\partial}{\partial y} (x^{3y}) = x^{2x} x^{3y} \cdot \ln x \cdot 3,$$

using the rule for the derivative of an exponential function as well as the chain rule. So $\boxed{f_y(x, y) = 3x^{2x+3y} \cdot \ln x}$.

89.

$$f_x(x, y, z) = \frac{\partial}{\partial x} (x^{y+z}) = (y+z)x^{y+z-1} \text{ (using the Power Rule)}$$

$$\boxed{f_x(x, y, z) = \frac{(y+z)x^{y+z}}{x}}.$$

$$\begin{aligned} f_y(x, y, z) &= \frac{\partial}{\partial y} (x^{y+z}) = \frac{\partial}{\partial y} (x^y \cdot x^z) = x^z \cdot \frac{\partial}{\partial y} (x^y) \\ &= x^z \cdot x^y \cdot \ln x \text{ (using the rule for the derivative of an exponential function, page 202)} \end{aligned}$$

$$\boxed{f_y(x, y, z) = x^{y+z} \ln x}.$$

$$\begin{aligned} f_z(x, y, z) &= \frac{\partial}{\partial z} (x^{y+z}) = \frac{\partial}{\partial z} (x^y \cdot x^z) = x^y \cdot \frac{\partial}{\partial z} (x^z) \\ &= x^y \cdot x^z \cdot \ln x \text{ (using the rule for the derivative of an exponential function, page 202)} \end{aligned}$$

$$\boxed{f_z(x, y, z) = x^{y+z} \ln x}.$$

90.

$$f_x(x, y, z) = \frac{\partial}{\partial x} (x^{yz}) = (yz)x^{yz-1} \text{ (using the Power Rule)}$$

$$\boxed{f_x(x, y, z) = \frac{yzx^{y+z}}{x}}.$$

$$\begin{aligned} f_y(x, y, z) &= \frac{\partial}{\partial y} (x^{yz}) = \frac{\partial}{\partial y} ((x^z)^y) \text{ (using the laws of exponents)} \\ &= (x^z)^y \cdot \ln(x^z) \text{ (using the rule for the derivative of an exponential function, page 202)} \\ &= x^{yz} \cdot z \ln x \end{aligned}$$

$$\boxed{f_y(x, y, z) = zx^{yz} \ln x}.$$

$$\begin{aligned} f_z(x, y, z) &= \frac{\partial}{\partial z} (x^{yz}) = \frac{\partial}{\partial z} ((x^y)^z) \text{ (using the laws of exponents)} \\ &= (x^y)^z \cdot \ln(x^y) \text{ (using the rule for the derivative of an exponential function, page 202)} \\ &= x^{yz} \cdot y \ln x \end{aligned}$$

$$\boxed{f_z(x, y, z) = yx^{yz} \ln x}.$$

91.

$$\begin{aligned} f_x(x, y, z) &= \frac{\partial}{\partial x} ((x+y)^z) = z(x+y)^{z-1} \cdot \frac{\partial}{\partial x} (x+y) \text{ (using the Power Rule and the Chain Rule)} \\ &= z(x+y)^{z-1} \cdot 1 = (x+y)^{z-1} z \end{aligned}$$

$$\boxed{f_x(x, y, z) = (x+y)^{z-1} z}$$

$$\begin{aligned} f_y(x, y, z) &= \frac{\partial}{\partial y} ((x+y)^z) = z(x+y)^{z-1} \cdot \frac{\partial}{\partial y} (x+y) \text{ (using the Power Rule and the Chain Rule)} \\ &= z(x+y)^{z-1} \cdot 1 = (x+y)^{z-1} z \end{aligned}$$

$$\boxed{f_y(x, y, z) = (x+y)^{z-1} z}$$

$$f_z(x, y, z) = \frac{\partial}{\partial z} ((x+y)^z), \text{ so } \boxed{f_z(x, y, z) = (x+y)^z \ln(x+y)}.$$

For the last computation, we used the rule for the derivative of an exponential function, page 202.

92.

$$\begin{aligned} f_x(x, y, z) &= \frac{\partial}{\partial x} ((xy)^z) = z(xy)^{z-1} \cdot \frac{\partial}{\partial x} (xy) \text{ (using the Power Rule and the Chain Rule)} \\ &= z(xy)^{z-1} \cdot y = x^{z-1} y^z z \end{aligned}$$

$$\boxed{f_x(x, y, z) = x^{z-1} y^z z}$$

$$\begin{aligned}
f_y(x, y, z) &= \frac{\partial}{\partial y} ((xy)^z) = z(xy)^{z-1} \cdot \frac{\partial}{\partial y} (xy) \quad (\text{using the Power Rule and the Chain Rule}) \\
&= z(xy)^{z-1} \cdot x = x^z y^{z-1} z
\end{aligned}$$

$$\boxed{f_y(x, y, z) = x^z y^{z-1} z}$$

$$f_z(x, y, z) = \frac{\partial}{\partial z} ((xy)^z), \text{ so } \boxed{f_z(x, y, z) = (xy)^z \ln(xy)}.$$

For the last computation, we used the rule for the derivative of an exponential function, page 202.

93.

$$\begin{aligned}
f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{e^{-\frac{1}{(\Delta x)^2 + 0}} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{e^{-\frac{1}{(\Delta x)^2}}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{1}{\Delta x}}{e^{\frac{1}{(\Delta x)^2}}} = \lim_{h \rightarrow 0} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}}.
\end{aligned}$$

Here we made the substitution $h = \Delta x$ for simplicity. So, we need to compute the limit

$$\lim_{h \rightarrow 0} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}}.$$

We will do so by computing the two one-sided limits,

$$\lim_{h \rightarrow 0^+} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}} \text{ and } \lim_{h \rightarrow 0^-} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}}.$$

Since $\lim_{h \rightarrow 0^+} \frac{1}{h} = \infty$ and $\lim_{h \rightarrow 0^+} e^{\frac{1}{h^2}} = \infty$, the quotient is an indeterminate form at 0^+ of type $\frac{\infty}{\infty}$. Therefore, we will apply L'Hôpital's Rule. Now,

$$\frac{d}{dh} \left(\frac{1}{h} \right) = \frac{d}{dh} (h^{-1}) = -h^{-2}$$

and

$$\frac{d}{dh} \left(e^{\frac{1}{h^2}} \right) = e^{\frac{1}{h^2}} \frac{d}{dh} \left(\frac{1}{h^2} \right) = e^{\frac{1}{h^2}} \frac{d}{dh} (h^{-2}) = e^{\frac{1}{h^2}} (-2h^{-3}).$$

Therefore, by L'Hôpital's Rule,

$$\lim_{h \rightarrow 0^+} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}} = \lim_{h \rightarrow 0^+} \frac{-h^{-2}}{e^{\frac{1}{h^2}} (-2h^{-3})} = \lim_{h \rightarrow 0^+} \frac{h}{2e^{\frac{1}{h^2}}} = 0,$$

since $\lim_{h \rightarrow 0^+} h = 0$ and $\lim_{h \rightarrow 0^+} 2e^{\frac{1}{h^2}} = \infty$.

Since $\lim_{h \rightarrow 0^-} \frac{1}{h} = -\infty$ and $\lim_{h \rightarrow 0^-} e^{\frac{1}{h^2}} = \infty$, the quotient is an indeterminate form at 0^- of type $\frac{\infty}{\infty}$. Therefore, we will apply L'Hôpital's Rule. The derivatives of the numerator and denominator are the same as they were above; therefore, by L'Hôpital's Rule,

$$\lim_{h \rightarrow 0^-} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}} = \lim_{h \rightarrow 0^-} \frac{-h^{-2}}{e^{\frac{1}{h^2}} (-2h^{-3})} = \lim_{h \rightarrow 0^-} \frac{h}{2e^{\frac{1}{h^2}}} = 0,$$

since $\lim_{h \rightarrow 0^-} h = 0$ and $\lim_{h \rightarrow 0^-} 2e^{\frac{1}{h^2}} = \infty$. Since both one-sided limits equal zero, we conclude that $\lim_{h \rightarrow 0} \frac{1}{e^{\frac{1}{h^2}}} = 0$. Therefore, $\boxed{f_x(0,0) = 0}$.

$$\begin{aligned} f_y(0,0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0,0+\Delta y) - f(0,0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0,\Delta y) - f(0,0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{e^{-\frac{1}{0+(\Delta y)^2}} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{e^{-\frac{1}{(\Delta y)^2}}}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\frac{1}{\Delta y}}{e^{\frac{1}{(\Delta y)^2}}} = \lim_{h \rightarrow 0} \frac{\frac{1}{h}}{e^{\frac{1}{h^2}}}. \end{aligned}$$

Here we made the substitution $h = \Delta y$ for simplicity. We then realize that this limit is identical to the one that we computed when we computed $f_x(0,0)$, so it must also equal 0. Therefore, $\boxed{f_y(0,0) = 0}$.

94. We will use logarithmic differentiation (see page 225). We start by taking the natural logarithm of each side:

$$\begin{aligned} \ln f(x,y) &= \ln(xy)^{xy} \\ \ln f(x,y) &= xy \ln(xy) \text{ (using the properties of logarithms)} \end{aligned}$$

To compute f_x , we use implicit differentiation (we take the derivative of each side with respect to x , keeping y constant):

$$\begin{aligned} \frac{\partial}{\partial x} (\ln f(x,y)) &= \frac{\partial}{\partial x} (xy \ln(xy)) \\ \frac{1}{f(x,y)} \frac{\partial}{\partial x} (f(x,y)) &= y \cdot \frac{\partial}{\partial x} (x \ln(xy)) \\ \frac{1}{f(x,y)} \frac{\partial}{\partial x} (f(x,y)) &= y \left(\frac{\partial}{\partial x} (x) \cdot \ln(xy) + x \cdot \frac{\partial}{\partial x} (\ln(xy)) \right) \\ \frac{1}{f(x,y)} f_x(x,y) &= y \left(\ln(xy) + x \cdot \frac{1}{xy} \frac{\partial}{\partial x} (xy) \right) \\ \frac{1}{f(x,y)} f_x(x,y) &= y \left(\ln(xy) + x \frac{y}{xy} \right) \\ \frac{1}{f(x,y)} f_x(x,y) &= y \ln(xy) + y = y(\ln(xy) + 1) \end{aligned}$$

Multiplying both sides by $f(x,y)$, we get

$$f_x(x,y) = y \cdot f(x,y) (\ln(xy) + 1) = y(xy)^{xy} (\ln(xy) + 1).$$

So $\boxed{f_x(x,y) = y(xy)^{xy} (\ln(xy) + 1)}$.

To compute f_y , we use implicit differentiation again (we take the derivative of each side with respect

to y , keeping x constant):

$$\begin{aligned}
\frac{\partial}{\partial y} (\ln f(x, y)) &= \frac{\partial}{\partial y} (xy \ln(xy)) \\
\frac{1}{f(x, y)} \frac{\partial}{\partial y} (f(x, y)) &= x \cdot \frac{\partial}{\partial y} (y \ln(xy)) \\
\frac{1}{f(x, y)} \frac{\partial}{\partial y} (f(x, y)) &= x \left(\frac{\partial}{\partial y} (y) \cdot \ln(xy) + y \cdot \frac{\partial}{\partial y} (\ln(xy)) \right) \\
\frac{1}{f(x, y)} f_y(x, y) &= x \left(\ln(xy) + y \cdot \frac{1}{xy} \frac{\partial}{\partial y} (xy) \right) \\
\frac{1}{f(x, y)} f_y(x, y) &= x \left(\ln(xy) + y \frac{x}{xy} \right) \\
\frac{1}{f(x, y)} f_y(x, y) &= x \ln(xy) + x = x(\ln(xy) + 1)
\end{aligned}$$

Multiplying both sides by $f(x, y)$, we get

$$f_y(x, y) = x \cdot f(x, y) (\ln(xy) + 1) = x(xy)^{xy} (\ln(xy) + 1).$$

So $\boxed{f_y(x, y) = x(xy)^{xy} (\ln(xy) + 1)}$.

Since we already know the first partial derivatives of f , we do not need to use logarithmic differentiation to compute the second partial derivatives. We use the Product Rule.

$$\begin{aligned}
f_{xx}(x, y) &= \frac{\partial}{\partial x} (f_x(x, y)) = \frac{\partial}{\partial x} (y(xy)^{xy} (\ln(xy) + 1)) = y \cdot \frac{\partial}{\partial x} ((xy)^{xy} (\ln(xy) + 1)) \\
&= y \left[\left(\frac{\partial}{\partial x} ((xy)^{xy}) \right) \cdot (\ln(xy) + 1) + (xy)^{xy} \cdot \frac{\partial}{\partial x} (\ln(xy) + 1) \right] \\
&= y \left[(y(xy)^{xy}) (\ln(xy) + 1) (\ln(xy) + 1) + (xy)^{xy} \cdot \frac{\frac{\partial}{\partial x} (xy)}{xy} \right] \\
&= y \left[(y(xy)^{xy}) (\ln(xy) + 1) (\ln(xy) + 1) + (xy)^{xy} \cdot \frac{y}{xy} \right] \\
&= y^2 (xy)^{xy} (\ln(xy) + 1)^2 + \frac{y}{x} \cdot (xy)^{xy} \\
&= (xy)^{xy} \left(y^2 (\ln(xy) + 1)^2 + \frac{y}{x} \right)
\end{aligned}$$

$$\boxed{f_{xx}(x, y) = (xy)^{xy} \left(y^2 (\ln(xy) + 1)^2 + \frac{y}{x} \right)}$$

$$\begin{aligned}
f_{yy}(x, y) &= \frac{\partial}{\partial y} (f_y(x, y)) = \frac{\partial}{\partial y} (x(xy)^{xy} (\ln(xy) + 1)) = x \cdot \frac{\partial}{\partial y} ((xy)^{xy} (\ln(xy) + 1)) \\
&= x \left[\left(\frac{\partial}{\partial y} ((xy)^{xy}) \right) \cdot (\ln(xy) + 1) + (xy)^{xy} \cdot \frac{\partial}{\partial y} (\ln(xy) + 1) \right] \\
&= x \left[(x(xy)^{xy} (\ln(xy) + 1) (\ln(xy) + 1) + (xy)^{xy} \cdot \frac{\frac{\partial}{\partial y} (xy)}{xy} \right] \\
&= x \left[(x(xy)^{xy} (\ln(xy) + 1) (\ln(xy) + 1) + (xy)^{xy} \cdot \frac{x}{xy} \right] \\
&= x^2 (xy)^{xy} (\ln(xy) + 1)^2 + \frac{x}{y} \cdot (xy)^{xy} \\
&= (xy)^{xy} \left(x^2 (\ln(xy) + 1)^2 + \frac{x}{y} \right)
\end{aligned}$$

$$f_{yy}(x, y) = (xy)^{xy} \left(x^2 (\ln(xy) + 1)^2 + \frac{x}{y} \right)$$

$$\begin{aligned}
f_{xy}(x, y) &= \frac{\partial}{\partial y} (f_x(x, y)) = \frac{\partial}{\partial y} (y(xy)^{xy} (\ln(xy) + 1)) = \frac{\partial}{\partial y} ((xy)^{xy} (y \ln(xy) + y)) \\
&= \left(\frac{\partial}{\partial y} ((xy)^{xy}) \right) \cdot (y \ln(xy) + y) + (xy)^{xy} \cdot \frac{\partial}{\partial y} (y \ln(xy) + y) \\
&= x(xy)^{xy} (\ln(xy) + 1) (y \ln(xy) + y) + (xy)^{xy} \left(\frac{\partial}{\partial y} (y) \cdot \ln(xy) + y \cdot \frac{\partial}{\partial y} (\ln(xy)) + \frac{\partial}{\partial y} (y) \right) \\
&= x(xy)^{xy} (\ln(xy) + 1) (y \ln(xy) + y) + (xy)^{xy} \left(\ln(xy) + y \cdot \frac{\frac{\partial}{\partial y} (xy)}{xy} + 1 \right) \\
&= xy(xy)^{xy} (\ln(xy) + 1)^2 + (xy)^{xy} \left(\ln(xy) + y \cdot \frac{x}{xy} + 1 \right) \\
&= (xy)^{xy} (xy (\ln(xy) + 1)^2 + \ln(xy) + 2)
\end{aligned}$$

$$f_{xy}(x, y) = (xy)^{xy} (xy (\ln(xy) + 1)^2 + \ln(xy) + 2)$$

Based on the definition of exponential function (page 202), the domain of f is the set of points (x, y) such that $xy > 0$ and $xy \neq 1$. In other words, the domain of f is $\{(x, y) | xy > 0 \text{ and } xy \neq 1\}$.

95. Since $f(x, y)$ is defined to be $\frac{x^3 - y^3}{x^2 + y^2}$ for all $(x, y) \neq (0, 0)$, and $\frac{x^3 - y^3}{x^2 + y^2}$ is a quotient of polynomials, with a nonzero denominator for all $(x, y) \neq (0, 0)$, we conclude that f has first partial derivatives at (x, y) for all $(x, y) \neq (0, 0)$. So, all that remains to be done is to verify that f has first partial derivatives at $(0, 0)$. We do so by using the definition of a partial derivative:

$$\begin{aligned}
f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x)^3 - 0}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\Delta x}{\Delta x} = \lim_{\Delta x \rightarrow 0} 1 = 1
\end{aligned}$$

$$\begin{aligned}
f_y(0,0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0,0+\Delta y) - f(0,0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0,\Delta y) - f(0,0)}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{0-(\Delta y)^3}{0+(\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{-\Delta y}{\Delta y} = \lim_{\Delta y \rightarrow 0} -1 = -1
\end{aligned}$$

So $f_x(0,0) = 1$ and $f_y(0,0) = -1$, and therefore we conclude that f has first partial derivatives at all points in the plane.

96.

$$f_r(r, \theta) = \frac{\partial}{\partial r} (r^n \sin(n\theta)) = \sin(n\theta) \frac{\partial}{\partial r} (r^n) = \sin(n\theta) \cdot nr^{n-1} = nr^{n-1} \sin(n\theta)$$

$$\begin{aligned}
f_{rr}(r, \theta) &= \frac{\partial}{\partial r} (f_r(r, \theta)) = \frac{\partial}{\partial r} (nr^{n-1} \sin(n\theta)) \\
&= n \sin(n\theta) \frac{\partial}{\partial r} (r^{n-1}) = n \sin(n\theta) \cdot (n-1)r^{n-2} = n(n-1)r^{n-2} \sin(n\theta)
\end{aligned}$$

$$f_\theta(r, \theta) = \frac{\partial}{\partial \theta} (r^n \sin(n\theta)) = r^n \frac{\partial}{\partial \theta} (\sin(n\theta)) = r^n \cos(n\theta) \cdot \frac{\partial}{\partial \theta} (n\theta) = r^n \cos(n\theta) \cdot n = nr^n \cos(n\theta)$$

$$\begin{aligned}
f_{\theta\theta}(r, \theta) &= \frac{\partial}{\partial \theta} (f_\theta(r, \theta)) = \frac{\partial}{\partial \theta} (nr^n \cos(n\theta)) \\
&= nr^n \frac{\partial}{\partial \theta} (\cos(n\theta)) = nr^n (-\sin(n\theta)) \cdot \frac{\partial}{\partial \theta} (n\theta) = nr^n (-\sin(n\theta)) \cdot n = -n^2 r^n \sin(n\theta)
\end{aligned}$$

So,

$$\begin{aligned}
&f_{rr}(r, \theta) + \frac{1}{r} f_r(r, \theta) + \frac{1}{r^2} f_{\theta\theta}(r, \theta) \\
&= n(n-1)r^{n-2} \sin(n\theta) + \frac{1}{r} \cdot nr^{n-1} \sin(n\theta) + \frac{1}{r^2} (-n^2 r^n \sin(n\theta)) \\
&= n(n-1)r^{n-2} \sin(n\theta) + nr^{n-2} \sin(n\theta) - n^2 r^{n-2} \sin(n\theta) \\
&= (n(n-1) + n - n^2) r^{n-2} \sin(n\theta) = 0 \cdot r^{n-2} \sin(n\theta) = 0.
\end{aligned}$$

Therefore, $f(r, \theta) = r^n \sin(n\theta)$ satisfies the equation

$$f_{rr} + \frac{1}{r} f_r + \frac{1}{r^2} f_{\theta\theta} = 0.$$

97. For all m , we have

$$\frac{\partial u}{\partial r} = \frac{\partial}{\partial r} (r^m \cos(m\theta)) = \cos(m\theta) \frac{\partial}{\partial r} (r^m) = \cos(m\theta) \cdot mr^{m-1} = mr^{m-1} \cos(m\theta)$$

$$\begin{aligned}
\frac{\partial^2 u}{\partial r^2} &= \frac{\partial}{\partial r} \left(\frac{\partial u}{\partial r} \right) = \frac{\partial}{\partial r} (mr^{m-1} \cos(m\theta)) \\
&= m \cos(m\theta) \frac{\partial}{\partial r} (r^{m-1}) = m \cos(m\theta) \cdot (m-1)r^{m-2} = m(m-1)r^{m-2} \cos(m\theta)
\end{aligned}$$

$$\begin{aligned}
\frac{\partial u}{\partial \theta} &= \frac{\partial}{\partial \theta} (r^m \cos(m\theta)) \\
&= r^m \frac{\partial}{\partial \theta} (\cos(m\theta)) = r^m (-\sin(m\theta)) \cdot \frac{\partial}{\partial \theta} (m\theta) = r^m (-\sin(m\theta)) \cdot m = -mr^m \sin(m\theta)
\end{aligned}$$

$$\begin{aligned}
\frac{\partial^2 u}{\partial \theta^2} &= \frac{\partial}{\partial \theta} \left(\frac{\partial u}{\partial \theta} \right) = \frac{\partial}{\partial \theta} (-mr^m \sin(m\theta)) \\
&= -mr^m \frac{\partial}{\partial \theta} (\sin(m\theta)) = -mr^m (\cos(m\theta)) \cdot \frac{\partial}{\partial \theta} (m\theta) = -mr^m (\cos(m\theta)) \cdot m = -m^2 r^m \cos(m\theta)
\end{aligned}$$

So,

$$\begin{aligned}
&\frac{\partial^2 u}{\partial r^2} + \frac{1}{r^2} \left(\frac{\partial^2 u}{\partial \theta^2} \right) + \frac{1}{r} \left(\frac{\partial u}{\partial r} \right) \\
&= m(m-1)r^{m-2} \cos(m\theta) + \frac{1}{r^2} (-m^2 r^m \cos(m\theta)) + \frac{1}{r} (mr^{m-1} \cos(m\theta)) \\
&= m(m-1)r^{m-2} \cos(m\theta) - m^2 r^{m-2} \cos(m\theta) + mr^{m-2} \cos(m\theta) \\
&= (m(m-1) - m^2 + m) r^{m-2} \cos(m\theta) = 0 \cdot r^{m-2} \cos(m\theta) = 0.
\end{aligned}$$

Therefore, $u = r^m \cos(m\theta)$ satisfies the equation

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r^2} \left(\frac{\partial^2 u}{\partial \theta^2} \right) + \frac{1}{r} \left(\frac{\partial u}{\partial r} \right) = 0,$$

for all m .

98. (a) The slope of the tangent line at $(x_0, y_0, f(x_0, y_0))$ to the curve of intersection of $z = f(x, y)$ and $y = y_0$ is the partial derivative $f_x(x_0, y_0)$. One point on the tangent line is $(x_0, y_0, f(x_0, y_0))$, and the tangent line lies on the plane $y = y_0$. Therefore, if $f_x(x_0, y_0) \neq 0$, the symmetric equations of the tangent line are:

$$\frac{z - f(x_0, y_0)}{f_x(x_0, y_0)} = x - x_0, \quad y = y_0.$$

If the partial derivative $f_x(x_0, y_0)$ is 0, then the slope of the curve in the plane $y = y_0$ is 0, and so the curve is the constant curve $z = f(x_0, y_0)$. The symmetric equations are then given by

$$z = f(x_0, y_0), y = y_0$$

The slope of the tangent line at $(x_0, y_0, f(x_0, y_0))$ to the curve of intersection of $z = f(x, y)$ and $x = x_0$ is the partial derivative $f_y(x_0, y_0)$. One point on the tangent line is $(x_0, y_0, f(x_0, y_0))$, and the tangent line lies on the plane $x = x_0$. Therefore, if $f_y(x_0, y_0) \neq 0$, the symmetric equations of the tangent line are:

$$\frac{z - f(x_0, y_0)}{f_y(x_0, y_0)} = y - y_0, \quad x = x_0.$$

If the partial derivative $f_y(x_0, y_0)$ is 0, then the slope of the curve in the plane $x = x_0$ is 0, and so the curve is the constant curve $z = f(x_0, y_0)$. The symmetric equations are then given by

$$z = f(x_0, y_0), x = x_0$$

- (b) From the symmetric equations, we can see that the first tangent line is in the direction of the vector $\mathbf{i} + f_x(x_0, y_0)\mathbf{k}$, and the second tangent line is in the direction of the vector $\mathbf{j} + f_y(x_0, y_0)\mathbf{k}$. Therefore, the vector

$$\begin{aligned}
\mathbf{N} &= (\mathbf{i} + f_x(x_0, y_0)\mathbf{k}) \times (\mathbf{j} + f_y(x_0, y_0)\mathbf{k}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & f_x(x_0, y_0) \\ 0 & 1 & f_y(x_0, y_0) \end{vmatrix} \\
&= \begin{vmatrix} 0 & f_x(x_0, y_0) \\ 1 & f_y(x_0, y_0) \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & f_x(x_0, y_0) \\ 0 & f_y(x_0, y_0) \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} \mathbf{k} = -f_x(x_0, y_0)\mathbf{i} - f_y(x_0, y_0)\mathbf{j} + \mathbf{k}
\end{aligned}$$

is orthogonal to both tangent lines, and is therefore a normal vector to the plane determined by the two lines. Since the plane contains the point $(x_0, y_0, f(x_0, y_0))$, we conclude that an equation of the plane is

$$-f_x(x_0, y_0)(x - x_0) - f_y(x_0, y_0)(y - y_0) + (z - z_0) = 0,$$

which we can also write as $\boxed{z - z_0 = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)}$.

(c) Answers will vary.

99. (a)

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} (3x^2 + 4y^3) = \frac{\partial}{\partial x} (3x^2) + \frac{\partial}{\partial x} (4y^3) = 6x + 0 = 6x \\ f_x(1, 6) &= 6 \cdot 1 \end{aligned}$$

$$\boxed{f_x(1, 6) = 6}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} (3x^2 + 4y^3) = \frac{\partial}{\partial y} (3x^2) + \frac{\partial}{\partial y} (4y^3) = 0 + 12y^2 = 12y^2 \\ f_y(1, 6) &= 12 \cdot 6^2 \end{aligned}$$

$$\boxed{f_y(1, 6) = 432}$$

(b) Suppose that we would like to determine the $x'y'$ -coordinates of a point (x, y) . Imagine rotating the entire plane 45° clockwise about the origin. Then the x' -axis is mapped to the x -axis, and the y' -axis is mapped to the y -axis. Therefore, the point (x, y) must be mapped to the point (x', y') ; this means that (x', y') is the result of rotating the point (x, y) 45° clockwise about the origin. Or, (x, y) is the result of rotating the point (x', y') 45° counterclockwise about the origin. In other words, if we write $x' = r \cos \theta$ and $y' = r \sin \theta$ (using polar coordinates), then $x = r \cos(\theta + 45^\circ)$ and $y = r \sin(\theta + 45^\circ)$. Using trigonometric identities, we obtain

$$\begin{aligned} x &= r \cos(\theta + 45^\circ) = r (\cos \theta \cos 45^\circ - \sin \theta \sin 45^\circ) = r \cos \theta \cos 45^\circ - r \sin \theta \sin 45^\circ \\ &= \frac{\sqrt{2}}{2} r \cos \theta - \frac{\sqrt{2}}{2} r \sin \theta = \frac{\sqrt{2}}{2} x' - \frac{\sqrt{2}}{2} y' = \frac{\sqrt{2}}{2} (x' - y') \\ y &= r \sin(\theta + 45^\circ) = r (\sin \theta \cos 45^\circ + \cos \theta \sin 45^\circ) = r \sin \theta \cos 45^\circ + r \cos \theta \sin 45^\circ \\ &= \frac{\sqrt{2}}{2} r \sin \theta + \frac{\sqrt{2}}{2} r \cos \theta = \frac{\sqrt{2}}{2} y' + \frac{\sqrt{2}}{2} x' = \frac{\sqrt{2}}{2} (x' + y') \end{aligned}$$

So,

$$f(x, y) = 3x^2 + 4y^3 = 3 \left(\frac{\sqrt{2}}{2} (x' - y') \right)^2 + 4 \left(\frac{\sqrt{2}}{2} (x' + y') \right)^3 = \frac{3}{2} (x' - y')^2 + \sqrt{2} (x' + y')^3$$

Therefore, $\bar{f}(x', y') = \frac{3}{2} (x' - y')^2 + \sqrt{2} (x' + y')^3$. It follows that:

$$\begin{aligned} \bar{f}_{x'}(x', y') &= \frac{3}{2} \cdot \frac{\partial}{\partial x'} ((x' - y')^2) + \sqrt{2} \cdot \frac{\partial}{\partial x'} ((x' + y')^3) \\ &= \frac{3}{2} \cdot 2(x' - y') \frac{\partial}{\partial x'} (x' - y') + \sqrt{2} \cdot 3(x' + y')^2 \frac{\partial}{\partial x'} (x' + y') \\ &= 3(x' - y') + 3\sqrt{2} (x' + y')^2 \\ \bar{f}_{y'}(x', y') &= \frac{3}{2} \cdot \frac{\partial}{\partial y'} ((x' - y')^2) + \sqrt{2} \cdot \frac{\partial}{\partial y'} ((x' + y')^3) \\ &= \frac{3}{2} \cdot 2(x' - y') \frac{\partial}{\partial y'} (x' - y') + \sqrt{2} \cdot 3(x' + y')^2 \frac{\partial}{\partial y'} (x' + y') \\ &= -3(x' - y') + 3\sqrt{2} (x' + y')^2 \end{aligned}$$

Now we need to determine (a, b) . Using the above equations, we have $1 = \frac{\sqrt{2}}{2}(a - b)$ and $6 = \frac{\sqrt{2}}{2}(a + b)$. So, $a - b = \frac{1}{\frac{\sqrt{2}}{2}} = \sqrt{2}$ and $a + b = \frac{6}{\frac{\sqrt{2}}{2}} = 6\sqrt{2}$. Adding these last two equations gives $2a = 7\sqrt{2}$, while subtracting the first from the second gives $2b = 5\sqrt{2}$. So, $(a, b) = (\frac{7\sqrt{2}}{2}, \frac{5\sqrt{2}}{2})$. Therefore,

$$\bar{f}_{x'}(a, b) = 3(a - b) + 3\sqrt{2}(a + b)^2 = 3\sqrt{2} + 3\sqrt{2} \cdot 72 = 219\sqrt{2}$$

$$\boxed{\bar{f}_{x'}(a, b) = 219\sqrt{2} \approx 309.713}$$

$$\bar{f}_{y'}(a, b) = -3(a - b) + 3\sqrt{2}(a + b)^2 = -3\sqrt{2} + 3\sqrt{2} \cdot 72 = 213\sqrt{2}$$

$$\boxed{\bar{f}_{y'}(a, b) = 213\sqrt{2} \approx 301.227}$$

Chapter 12: Functions of Several Variables

12.4: Differentiability and the Differential

Concepts and Vocabulary

1. True. The change in z , Δz , from $(0.9, 0)$ to $(1, \frac{\pi}{4})$, is defined as

$$f\left(1, \frac{\pi}{4}\right) - f(0.9, 0) = (1) \sin\left(\frac{\pi}{4}\right) - (0.9) \sin 0 = \frac{\sqrt{2}}{2}.$$

2. True. Note that both f_x and f_y exist in a disk centered at $(0, 2)$ (we can choose the disk of radius $\frac{1}{2}$ for example), and f_x and f_y are both continuous at $(0, 2)$, so f is differentiable at $(0, 2)$. Recall that the continuity of the partial derivatives f_x and f_y implies the differentiability of f .
3. True. The differential dz of z at $(0, \frac{\pi}{2})$ is defined as $dz = f_x\left(0, \frac{\pi}{2}\right) dx + f_y\left(0, \frac{\pi}{2}\right) dy$. We have that $f_x = e^x \cos y$ and $f_y = -e^x \sin y$, so $f_x\left(0, \frac{\pi}{2}\right) = e^0 \cos\left(\frac{\pi}{2}\right) = (1)(0) = 0$ and $f_y\left(0, \frac{\pi}{2}\right) = -e^0 \sin\left(\frac{\pi}{2}\right) = -(1)(1) = -1$. This yields:

$$dz = 0 \cdot dx + -1 \cdot dy = -dy.$$

4. True. Note that f_x and f_y exist and are continuous everywhere since they are both polynomial functions, and the continuity of the partial derivatives f_x and f_y implies the continuity of f .
5. True. Note that f_x and f_y exist and are continuous everywhere since they are both polynomial functions, and the continuity of the partial derivatives f_x and f_y implies the differentiability of f .
6. False. The differential dw is defined as $dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$, and we have the following partial derivatives:

$$f_x(x, y, z) = e^{xyz}(yz) = yze^{xyz}$$

$$f_y(x, y, z) = e^{xyz}(xz) = xze^{xyz}$$

$$f_z(x, y, z) = e^{xyz}(xy) = xye^{xyz}$$

This yields $dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz = yze^{xyz}dx + xze^{xyz}dy + xye^{xyz}dz \neq yze^x dx + xze^y dy + xye^z dz$.

Skill Building

7. We compute $\Delta z = f(1.1, 3.2) - f(1, 3)$:

$$f(1.1, 3.2) = 1.1^2 + 3.2^2 = 11.45$$

$$f(1, 3) = 1^2 + 3^2 = 10$$

So, the change in z is $\Delta z = 11.45 - 10$, or $\boxed{\Delta z = 1.45}$.

8. We compute $\Delta z = f(2.1, -1.1) - f(2, -1)$:

$$f(2.1, -1.1) = 2(2.1)^2 + (2.1)(-1.1) - (-1.1)^2 = 5.3$$

$$f(2, -1) = 2(2)^2 + (2)(-1) - (-1)^2 = 5$$

So, the change in z is $\Delta z = 5.3 - 5$, or $\boxed{\Delta z = 0.3}$.

9. We compute $\Delta z = f(0.9, 2.1) - f(1, 2)$:

$$f(0.9, 2.1) = e^{0.9} \ln[(0.9)(2.1)] \approx 1.566$$

$$f(1, 2) = e^1 \ln[(1)(2)] \approx 1.884$$

So, the change in z is $\Delta z \approx 1.566 - 1.884$, or $\boxed{\Delta z \approx -0.318}$.

10. We compute $\Delta z = f(-0.9, 1.9) - f(-1, 2)$:

$$f(-0.9, 1.9) = \frac{(-0.9)(1.9)}{-0.9 + 1.9} = -1.71$$

$$f(-1, 2) = \frac{(-1)(2)}{-1 + 2} = -2$$

So, the change in z is $\Delta z = -1.71 - (-2)$, or $\boxed{\Delta z = 0.29}$.

11. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned} f_x(x, y) &= 2x \\ f_y(x, y) &= 2y \end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$\boxed{dz = 2x dx + 2y dy}.$$

12. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= 4x + y \\f_y(x, y) &= x - 2y\end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$dz = (4x + y) dx + (x - 2y) dy.$$

13. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= \sin y + y \cos x \\f_y(x, y) &= x \cos y + \sin x\end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$dz = (\sin y + y \cos x) dx + (x \cos y + \sin x) dy.$$

14. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= e^x \cos y + e^x \cdot \frac{\partial}{\partial x}(-x) \cdot \sin y = e^x \cos y - e^x \sin y \\f_y(x, y) &= -e^x \sin y + e^{-x} \cos y\end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$dz = (e^x \cos y - e^x \sin y) dx + (-e^x \sin y + e^{-x} \cos y) dy.$$

15. $f(x, y)$ is defined everywhere in the xy -plane, except when $x = 0$ (because of the denominator x). The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{\partial}{\partial x} \left(\frac{y}{x}\right) = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(-\frac{y}{x^2}\right) = \frac{-y}{x^2 + y^2} \\f_y(x, y) &= \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{\partial}{\partial y} \left(\frac{y}{x}\right) = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(\frac{1}{x}\right) = \frac{1}{x + \frac{y^2}{x}} = \frac{x}{x^2 + y^2}\end{aligned}$$

Now, f_x and f_y are continuous everywhere in the domain of f (because, if $x \neq 0$, then the denominator of $f_x(x, y)$ and $f_y(x, y)$, which is $x^2 + y^2$, cannot be zero). So, the function $z = f(x, y)$ is differentiable on its domain. The differential dz is

$$dz = \frac{-y}{x^2 + y^2} dx + \frac{x}{x^2 + y^2} dy.$$

16. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= \tan^{-1} y \\f_y(x, y) &= \frac{x}{1 + y^2}\end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$dz = \tan^{-1} y dx + \frac{x}{1 + y^2} dy.$$

17. In order for $f(x, y)$ to be defined, the argument of the logarithm, $\frac{y}{x}$, must be positive. This happens when x and y are both positive, or both negative.

So the domain of f is $\{(x, y) | x > 0, y > 0 \text{ or } x < 0, y < 0\}$. The partial derivatives of f are

$$\begin{aligned} f_x(x, y) &= \frac{1}{\left(\frac{y}{x}\right)} \cdot \frac{\partial}{\partial x} \left(\frac{y}{x}\right) = \frac{x}{y} \cdot \frac{-y}{x^2} = -\frac{1}{x} \\ f_y(x, y) &= \frac{1}{\left(\frac{y}{x}\right)} \cdot \frac{\partial}{\partial y} \left(\frac{y}{x}\right) = \frac{x}{y} \cdot \frac{1}{x} = \frac{1}{y} \end{aligned}$$

Now, f_x and f_y are continuous everywhere in the domain of f (because, if $x > 0, y > 0$ or $x < 0, y < 0$, then $x \neq 0$ and $y \neq 0$, so the denominators of $f_x(x, y)$ and $f_y(x, y)$ are both nonzero). So, the function $z = f(x, y)$ is differentiable on its domain. The differential dz is

$$\boxed{dz = -\frac{1}{x} dx + \frac{1}{y} dy}.$$

18. We see that the argument of the logarithm, $x^2 + y^2$, is always positive, except when $(x, y) = (0, 0)$. Therefore, f is defined everywhere in the xy -plane, except at the point $(0, 0)$. The partial derivatives of f are

$$\begin{aligned} f_x(x, y) &= \frac{1}{x^2 + y^2} \cdot \frac{\partial}{\partial x} (x^2 + y^2) = \frac{2x}{x^2 + y^2} \\ f_y(x, y) &= \frac{1}{x^2 + y^2} \cdot \frac{\partial}{\partial y} (x^2 + y^2) = \frac{2y}{x^2 + y^2} \end{aligned}$$

We see that the denominator of $f_x(x, y)$ and $f_y(x, y)$, which is $x^2 + y^2$, is always nonzero when $(x, y) \neq (0, 0)$. So, f_x and f_y are continuous everywhere in the domain of f , which implies that the function $z = f(x, y)$ is differentiable on its domain. The differential dz is

$$\boxed{dz = \frac{2x}{x^2 + y^2} dx + \frac{2y}{x^2 + y^2} dy}.$$

19. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned} f_x(x, y) &= e^{xy} \cdot \frac{\partial}{\partial x} (xy) = ye^{xy} \\ f_y(x, y) &= e^{xy} \cdot \frac{\partial}{\partial y} (xy) = xe^{xy} \end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$\boxed{dz = ye^{xy} dx + xe^{xy} dy}.$$

20. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned} f_x(x, y) &= e^{x^2+y} \cdot \frac{\partial}{\partial x} (x^2 + y) = 2xe^{x^2+y} \\ f_y(x, y) &= e^{x^2+y} \cdot \frac{\partial}{\partial y} (x^2 + y) = e^{x^2+y} \end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$\boxed{dz = 2xe^{x^2+y} dx + e^{x^2+y} dy}.$$

21. f is defined everywhere in the xy -plane. The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= 2xy \\f_y(x, y) &= x^2 + e^{y^2} \cdot \frac{\partial}{\partial y}(y^2) = x^2 + 2ye^{y^2}\end{aligned}$$

Since f_x and f_y are continuous everywhere in the xy -plane, the function $z = f(x, y)$ is differentiable. The differential dz is

$$\boxed{dz = 2xy \, dx + (x^2 + 2ye^{y^2}) \, dy}.$$

22. Since the argument of the logarithm, x^2 , is always positive, except when $x = 0$, we see that $f(x, y)$ is defined everywhere in the xy -plane, except when $x = 0$. The partial derivatives of f are

$$\begin{aligned}f_x(x, y) &= y^3 - \frac{1}{x^2} \cdot \frac{\partial}{\partial x}(x^2) = y^3 - \frac{2x}{x^2} = y^3 - \frac{2}{x} \\f_y(x, y) &= 3xy^2\end{aligned}$$

Now, f_x and f_y are continuous everywhere in the domain of f (because, if $x \neq 0$, then the denominator that appears in $f_x(x, y)$ is nonzero). So, the function $z = f(x, y)$ is differentiable on its domain. The differential dz is

$$\boxed{dz = \left(y^3 - \frac{2}{x}\right) dx + 3xy^2 \, dy}.$$

23. The function f is defined everywhere in space. We begin by computing the partial derivatives of f :

$$f_x(x, y, z) = e^{yz} + ye^{xz}(z) + ze^{xy}(y) = e^{yz} + yze^{xz} + yze^{xy}$$

$$f_y(x, y, z) = xe^{yz}(z) + e^{xz} + ze^{xy}(x) = xze^{yz} + e^{xz} + xze^{xy}$$

$$f_z(x, y, z) = xe^{yz}(y) + ye^{xz}(x) + e^{xy} = xye^{yz} + xye^{xz} + e^{xy}.$$

Since the partial derivatives are continuous everywhere, we have

$$dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$$

$$\boxed{dw = (e^{yz} + yze^{xz} + yze^{xy})dx + (xze^{yz} + e^{xz} + xze^{xy})dy + (xye^{yz} + xye^{xz} + e^{xy})dz}.$$

24. The function f is defined everywhere in space. We begin by computing the partial derivatives of f :

$$f_x(x, y, z) = 2xy + z^2$$

$$f_y(x, y, z) = x^2 + 2yz$$

$$f_z(x, y, z) = y^2 + (2z)x = y^2 + 2xz.$$

Since the partial derivatives are continuous everywhere, we have

$$dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$$

$$\boxed{dw = (2xy + z^2)dx + (x^2 + 2yz)dy + (y^2 + 2xz)dz}.$$

25. The function f is defined everywhere in space except the origin. We begin by computing the partial derivatives of f :

$$f_x(x, y, z) = \frac{1}{x^2 + y^2 + z^2}(2x) = \frac{2x}{x^2 + y^2 + z^2}$$

$$f_y(x, y, z) = \frac{1}{x^2 + y^2 + z^2}(2y) = \frac{2y}{x^2 + y^2 + z^2}$$

$$f_z(x, y, z) = \frac{1}{x^2 + y^2 + z^2}(2z) = \frac{2z}{x^2 + y^2 + z^2}.$$

Since the partial derivatives are continuous everywhere on the domain of the function f , we have

$$dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$$

$$dw = \frac{2x}{x^2 + y^2 + z^2}dx + \frac{2y}{x^2 + y^2 + z^2}dy + \frac{2z}{x^2 + y^2 + z^2}dz.$$

26. The function f is defined where $xy > 0$, $xz > 0$, and $yz > 0$. More specifically, these three inequalities will hold when either $x, y, z > 0$ or $x, y, z < 0$. We begin by computing the partial derivatives of f :

$$f_x(x, y, z) = \frac{1}{xy} \cdot y + \frac{1}{xz} \cdot z = \frac{1}{x} + \frac{1}{x} = \frac{2}{x}$$

$$f_y(x, y, z) = \frac{1}{xy} \cdot x + \frac{1}{yz} \cdot z = \frac{1}{y} + \frac{1}{y} = \frac{2}{y}$$

$$f_z(x, y, z) = \frac{1}{xz} \cdot x + \frac{1}{yz} \cdot y = \frac{1}{z} + \frac{1}{z} = \frac{2}{z}.$$

Since the partial derivatives are continuous everywhere on the domain of the function f , we have

$$dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$$

$$dw = \frac{2}{x}dx + \frac{2}{y}dy + \frac{2}{z}dz.$$

27. The function f is defined everywhere in space. We begin by computing the partial derivatives of f :

$$f_x(x, y, z) = yz$$

$$f_y(x, y, z) = xz$$

$$f_z(x, y, z) = xy.$$

Since the partial derivatives are continuous everywhere, we have

$$dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$$

$$dw = (yz)dx + (xz)dy + (xy)dz.$$

28. The function f is defined everywhere in space except the plane $x + y + z = 0$. We begin by computing the partial derivatives of f :

$$\begin{aligned} f_x(x, y, z) &= \frac{(yz)(x + y + z) - xyz(1)}{(x + y + z)^2} = \frac{xyz + y^2z + yz^2 - xyz}{(x + y + z)^2} = \frac{y^2z + yz^2}{(x + y + z)^2} \\ f_y(x, y, z) &= \frac{(xz)(x + y + z) - xyz(1)}{(x + y + z)^2} = \frac{x^2z + xyz + xz^2 - xyz}{(x + y + z)^2} = \frac{x^2z + xz^2}{(x + y + z)^2} \\ f_z(x, y, z) &= \frac{(xy)(x + y + z) - xyz(1)}{(x + y + z)^2} = \frac{x^2y + xy^2 + xyz - xyz}{(x + y + z)^2} = \frac{x^2y + xy^2}{(x + y + z)^2}. \end{aligned}$$

Since the partial derivatives are continuous everywhere on the domain of the function f , we have

$$dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$$

$$dw = \frac{y^2z + yz^2}{(x + y + z)^2} dx + \frac{x^2z + xz^2}{(x + y + z)^2} dy + \frac{x^2y + xy^2}{(x + y + z)^2} dz.$$

29. (a) We have that $\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y)$, so for the function $z = f(x, y) = xy^2 - 2xy$ we have

$$\begin{aligned} \Delta z &= f(x + \Delta x, y + \Delta y) - f(x, y) \\ &= (x + \Delta x)(y + \Delta y)^2 - 2(x + \Delta x)(y + \Delta y) - [xy^2 - 2xy] \\ &= (x + \Delta x)(y^2 + 2y\Delta y + (\Delta y)^2) - 2(xy + x\Delta y + y\Delta x + \Delta x\Delta y) - xy^2 + 2xy \\ &= xy^2 + 2xy\Delta y + x(\Delta y)^2 + y^2\Delta x + 2y\Delta x\Delta y + \Delta x(\Delta y)^2 - 2xy - 2x\Delta y - 2y\Delta x - 2\Delta x\Delta y - xy^2 + 2xy \\ &= 2xy\Delta y + x(\Delta y)^2 + y^2\Delta x + 2y\Delta x\Delta y + \Delta x(\Delta y)^2 - 2x\Delta y - 2y\Delta x - 2\Delta x\Delta y \\ &= (y^2 - 2y)\Delta x + (2xy - 2x)\Delta y + (2y\Delta y - 2\Delta y)\Delta x + (x\Delta y + \Delta x\Delta y)\Delta y \end{aligned}$$

$$\text{So, } \Delta z = (y^2 - 2y)\Delta x + (2xy - 2x)\Delta y + (2y\Delta y - 2\Delta y)\Delta x + (x\Delta y + \Delta x\Delta y)\Delta y.$$

- (b) Note that $f_x(x, y) = y^2 - 2y$ and $f_y(x, y) = 2xy - 2x$. So, we see from our manipulations from part (a) that we may choose η_1 and η_2 as follows:

$$\eta_1 = 2y\Delta y - 2\Delta y$$

$$\eta_2 = x\Delta y + \Delta x\Delta y,$$

which will yield $\Delta z = (y^2 - 2y)\Delta x + (2xy - 2x)\Delta y + \eta_1\Delta x + \eta_2\Delta y$. (Note that had we rearranged Δz differently in part (a), we may have had a different choice of η_1 and η_2 .)

- (c) We now show that $\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_1 = 0$ and $\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_2 = 0$. We have that

$$\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_1 = \lim_{\Delta y \rightarrow 0} [2y\Delta y - 2\Delta y] = 0$$

and

$$\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_2 = \lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} [x\Delta y + \Delta x\Delta y] = 0.$$

30. (a) We have that $\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y)$, so for the function $z = f(x, y) = 3x^2 + y^2$ we have

$$\begin{aligned} \Delta z &= f(x + \Delta x, y + \Delta y) - f(x, y) \\ &= 3(x + \Delta x)^2 + (y + \Delta y)^2 - [3x^2 + y^2] \end{aligned}$$

$$\begin{aligned}
&= 3(x^2 + 2x\Delta x + (\Delta x)^2) + y^2 + 2y\Delta y + (\Delta y)^2 - 3x^2 - y^2 \\
&= 3x^2 + 6x\Delta x + 3(\Delta x)^2 + y^2 + 2y\Delta y + (\Delta y)^2 - 3x^2 - y^2 \\
&= 6x\Delta x + 3(\Delta x)^2 + 2y\Delta y + (\Delta y)^2 \\
&= 6x\Delta x + 2y\Delta y + [3\Delta x]\Delta x + [\Delta y]\Delta y
\end{aligned}$$

So, $\boxed{\Delta z = 6x\Delta x + 2y\Delta y + [3\Delta x]\Delta x + [\Delta y]\Delta y}$.

- (b) Note that $f_x(x, y) = 6x$ and $f_y(x, y) = 2y$. So, we see from our manipulations from part (a) that we may choose η_1 and η_2 as follows:

$$\boxed{\eta_1 = 3\Delta x}$$

$$\boxed{\eta_2 = \Delta y},$$

which will yield $\Delta z = 6x\Delta x + 2y\Delta y + \eta_1\Delta x + \eta_2\Delta y$. (Note that in this case, there is no way to rearrange Δz differently in part (a), so these are our only correct choices of η_1 and η_2 .)

- (c) We now show that $\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_1 = 0$ and $\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_2 = 0$. We have that

$$\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_1 = \lim_{\Delta x \rightarrow 0} 3\Delta x = 0$$

and

$$\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_2 = \lim_{\Delta y \rightarrow 0} \Delta y = 0.$$

31. (a) We have that $\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y)$, so for the function $z = f(x, y) = \frac{y}{x}$ we have

$$\begin{aligned}
\Delta z &= f(x + \Delta x, y + \Delta y) - f(x, y) \\
&= \frac{y + \Delta y}{x + \Delta x} - \frac{y}{x} \\
&= \frac{(y + \Delta y)x - (x + \Delta x)y}{x(x + \Delta x)} \\
&= \frac{xy + x\Delta y - (xy + y\Delta x)}{x(x + \Delta x)} \\
&= \frac{xy + x\Delta y - xy - y\Delta x}{x(x + \Delta x)} \\
&= \frac{x\Delta y - y\Delta x}{x(x + \Delta x)} \\
&= \frac{x\Delta y - y\Delta x}{x(x + \Delta x)} - \frac{y}{x^2}\Delta x + \frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y - \frac{1}{x}\Delta y \\
&= -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \frac{x\Delta y - y\Delta x}{x(x + \Delta x)} + \frac{y}{x^2}\Delta x - \frac{1}{x}\Delta y \\
&= -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \frac{x\Delta y}{x(x + \Delta x)} + \frac{-y\Delta x}{x(x + \Delta x)} + \frac{y}{x^2}\Delta x - \frac{1}{x}\Delta y \\
&= -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \frac{\Delta y}{x + \Delta x} + \frac{-y\Delta x}{x(x + \Delta x)} + \frac{y}{x^2}\Delta x - \frac{1}{x}\Delta y \\
&= -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \frac{y}{x^2}\Delta x + \frac{-y\Delta x}{x(x + \Delta x)} - \frac{1}{x}\Delta y + \frac{\Delta y}{x + \Delta x} \\
&= -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \left[\frac{y}{x^2} - \frac{y}{x(x + \Delta x)} \right] \Delta x + \left[-\frac{1}{x} + \frac{1}{x + \Delta x} \right] \Delta y
\end{aligned}$$

So,
$$\Delta z = -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \left[\frac{y}{x^2} - \frac{y}{x(x+\Delta x)}\right]\Delta x + \left[-\frac{1}{x} + \frac{1}{x+\Delta x}\right]\Delta y.$$

- (b) Note that $f_x(x, y) = -\frac{y}{x^2}$ and $f_y(x, y) = \frac{1}{x}$. So, we see from our manipulations from part (a) that we may choose η_1 and η_2 as follows:

$$\eta_1 = \frac{y}{x^2} - \frac{y}{x(x+\Delta x)}$$

$$\eta_2 = -\frac{1}{x} + \frac{1}{x+\Delta x},$$

which will yield $\Delta z = -\frac{y}{x^2}\Delta x + \frac{1}{x}\Delta y + \eta_1\Delta x + \eta_2\Delta y$. (Note that had we rearranged Δz differently in part (a), we may have had a different choice of η_1 and η_2 .)

- (c) We now show that $\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_1 = 0$ and $\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_2 = 0$. We have that

$$\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_1 = \lim_{\Delta x \rightarrow 0} \left[\frac{y}{x^2} - \frac{y}{x(x+\Delta x)} \right] = \frac{y}{x^2} - \frac{y}{x^2} = 0$$

and

$$\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_2 = \lim_{\Delta x \rightarrow 0} \left[-\frac{1}{x} + \frac{1}{x+\Delta x} \right] = -\frac{1}{x} + \frac{1}{x} = 0.$$

32. (a) We have that $\Delta z = f(x+\Delta x, y+\Delta y) - f(x, y)$, so for the function $z = f(x, y) = \frac{2x}{y}$ we have

$$\begin{aligned} \Delta z &= f(x+\Delta x, y+\Delta y) - f(x, y) \\ &= \frac{2(x+\Delta x)}{y+\Delta y} - \frac{2x}{y} \\ &= \frac{2(x+\Delta x)y - 2x(y+\Delta y)}{y(y+\Delta y)} \\ &= \frac{2xy + 2y\Delta x - 2xy - 2x\Delta y}{y(y+\Delta y)} \\ &= \frac{2y\Delta x - 2x\Delta y}{y(y+\Delta y)} \\ &= \frac{2y\Delta x - 2x\Delta y}{y^2} - \frac{2x}{y^2}\Delta y + \frac{2x}{y^2}\Delta y + \frac{2}{y}\Delta x - \frac{2}{y}\Delta x \\ &= -\frac{2x}{y^2}\Delta y + \frac{2}{y}\Delta x + \frac{2y\Delta x - 2x\Delta y}{y^2} + \frac{2x}{y^2}\Delta y - \frac{2}{y}\Delta x \\ &= -\frac{2x}{y^2}\Delta y + \frac{2}{y}\Delta x + \frac{2y\Delta x}{y^2} - \frac{2x\Delta y}{y^2} + \frac{2x}{y^2}\Delta y - \frac{2}{y}\Delta x \\ &= -\frac{2x}{y^2}\Delta y + \frac{2}{y}\Delta x + \frac{2\Delta x}{y} - \frac{2x\Delta y}{y^2} + \frac{2x}{y^2}\Delta y - \frac{2}{y}\Delta x \\ &= -\frac{2x}{y^2}\Delta y + \frac{2}{y}\Delta x - \frac{2}{y}\Delta x + \frac{2\Delta x}{y} + \frac{2x}{y^2}\Delta y - \frac{2x\Delta y}{y^2} \\ &= -\frac{2x}{y^2}\Delta y + \frac{2}{y}\Delta x + \left[\frac{-2}{y} + \frac{2}{y+\Delta y} \right] \Delta x + \left[\frac{2x}{y^2} - \frac{2x}{y(y+\Delta y)} \right] \Delta y \end{aligned}$$

So,
$$\Delta z = \frac{2}{y}\Delta x - \frac{2x}{y^2}\Delta y + \left[\frac{-2}{y} + \frac{2}{y+\Delta y} \right] \Delta x + \left[\frac{2x}{y^2} - \frac{2x}{y(y+\Delta y)} \right] \Delta y.$$

- (b) Note that $f_x(x, y) = -\frac{2x}{y^2}$ and $f_y(x, y) = \frac{2}{y}$. So, we see from our manipulations from part (a) that we may choose η_1 and η_2 as follows:

$$\eta_1 = \frac{-2}{y} + \frac{2}{y + \Delta y}$$

$$\eta_2 = \frac{2x}{y^2} - \frac{2x}{y(y + \Delta y)},$$

which will yield $\Delta z = \frac{2}{y}\Delta x - \frac{2x}{y^2}\Delta y + \eta_1\Delta x + \eta_2\Delta y$. (Note that had we rearranged Δz differently in part (a), we may have had a different choice of η_1 and η_2 .)

- (c) We now show that $\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_1 = 0$ and $\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_2 = 0$. We have that

$$\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_1 = \lim_{\Delta y \rightarrow 0} \left[\frac{-2}{y} + \frac{2}{y + \Delta y} \right] = -\frac{2}{y} + \frac{2}{y} = 0$$

and

$$\lim_{(\Delta x, \Delta y) \rightarrow (0, 0)} \eta_2 = \lim_{\Delta y \rightarrow 0} \left[\frac{2x}{y^2} - \frac{2x}{y(y + \Delta y)} \right] = \frac{2x}{y^2} - \frac{2x}{y^2} = 0.$$

33. (a) We compute the differential dz for the function $z = f(x, y) = x^2 + y^2$ by first finding its partial derivatives at the point $(x_0, y_0) = (1, 3)$:

$$\begin{aligned} f_x(x, y) &= 2x \\ f_x(1, 3) &= 2(1) = 2 \end{aligned}$$

$$\begin{aligned} f_y(x, y) &= 2y \\ f_y(1, 3) &= 2(3) = 6 \end{aligned}$$

Also, $dx = \Delta x = 1.1 - 1 = 0.1$ and $dy = \Delta y = 3.2 - 3 = 0.2$. The differential is given by

$$\begin{aligned} dz &= f_x(1, 3)dx + f_y(1, 3)dy \\ &= 2(0.1) + 6(0.2) \\ &= 1.4. \end{aligned}$$

So, the approximate change in z is $\Delta z \approx dz = 1.4$.

- (b) We compare the approximated change, 1.4, with the actual change, computed in problem 7, which is $\Delta z = 1.45$.
34. (a) We compute the differential dz for the function $z = f(x, y) = 2x^2 + xy - y^2$ by first finding its partial derivatives at the point $(x_0, y_0) = (2, -1)$:

$$\begin{aligned} f_x(x, y) &= 4x + y \\ f_x(2, -1) &= 4(2) - 1 = 7 \end{aligned}$$

$$\begin{aligned} f_y(x, y) &= x - 2y \\ f_y(2, -1) &= 2 - 2(-1) = 4 \end{aligned}$$

Also, $dx = \Delta x = 2.1 - 2 = 0.1$ and $dy = \Delta y = -1.1 + 1 = -0.1$. The differential is given by

$$\begin{aligned} dz &= f_x(2, -1)dx + f_y(2, -1)dy \\ &= 7(0.1) + 4(-0.1) \\ &= 0.3. \end{aligned}$$

So, the approximate change in z is $\boxed{dz = 0.3}$.

- (b) We compare our approximated change, 0.3 to the actual change, computed in problem 8, which is $\boxed{\Delta z = 0.3}$.

35. (a) We compute the differential dz for the function $z = f(x, y) = e^x \ln(xy)$ by first finding its partial derivatives at the point $(x_0, y_0) = (1, 2)$:

$$f_x(x, y) = e^x \ln(xy) + e^x \left(\frac{1}{xy} \right) (y) = e^x \ln(xy) + \frac{e^x}{x}$$

$$f_x(1, 2) = e^1 \ln(1 \cdot 2) + \frac{e^1}{1} = e \ln 2 + e$$

$$f_y(x, y) = e^x \left(\frac{1}{xy} \right) (x) = \frac{e^x}{y}$$

$$f_y(1, 2) = \frac{e^1}{2} = \frac{e}{2}$$

Also, $dx = \Delta x = 0.9 - 1 = -0.1$ and $dy = \Delta y = 2.1 - 2 = 0.1$. The differential is given by

$$\begin{aligned} dz &= f_x(1, 2)dx + f_y(1, 2)dy \\ &= (e \ln 2 + e)(-0.1) + \frac{e}{2}(0.1) = -0.1e \ln 2 - 0.1e + 0.05e \\ &= -0.1e \ln 2 - .05e \approx -0.324. \end{aligned}$$

So, the approximate change in z is $\boxed{dz \approx -0.324}$.

- (b) We compare the approximated change, -0.324 , with the actual change, computed in problem 9, which is $\boxed{\Delta z \approx -0.318}$.

36. (a) We compute the differential dz for the function $z = f(x, y) = \frac{xy}{x+y}$ by first finding its partial derivatives at the point $(x_0, y_0) = (-1, 2)$:

$$f_x(x, y) = \frac{y(x+y) - (xy)(1)}{(x+y)^2} = \frac{xy + y^2 - xy}{(x+y)^2} = \frac{y^2}{(x+y)^2}$$

$$f_x(-1, 2) = \frac{2^2}{(-1+2)^2} = 4$$

$$f_y(x, y) = \frac{x(x+y) - (xy)(1)}{(x+y)^2} = \frac{x^2 + xy - xy}{(x+y)^2} = \frac{x^2}{(x+y)^2}$$

$$f_y(-1, 2) = \frac{(-1)^2}{(-1+2)^2} = 1$$

Also, $dx = \Delta x = -0.9 + 1 = 0.1$ and $dy = \Delta y = 1.9 - 2 = -0.1$. The differential is given by

$$\begin{aligned} dz &= f_x(-1, 2)dx + f_y(-1, 2)dy \\ &= (4)(0.1) + (1)(-0.1) \\ &= 0.3. \end{aligned}$$

So, the approximate change in z is $\boxed{dz = 0.3}$.

- (b) We compare the approximated change, 0.3, with the actual change, computed in problem 10, which is $\boxed{\Delta z = 0.29}$.

Applications and Extensions

37. We approximate the increase in the area of the triangle using the differential dA , where A is the area of the triangle. The formula for the area of a triangle of base b and height h is $A = \frac{1}{2}bh$. We compute the partial derivatives of A with respect to b and h at the point $(b, h) = (2, 5)$ in order to find the differential:

$$A_b(b, h) = \frac{1}{2}h$$

$$A_b(2, 5) = \frac{1}{2}(5) = \frac{5}{2}$$

$$A_h(b, h) = \frac{1}{2}b$$

$$A_h(2, 5) = \frac{1}{2}(2) = 1.$$

Also, $db = \Delta b = 2.05 - 2 = 0.05$ and $dh = \Delta h = 5.1 - 5 = 0.1$. The differential dA is then given by:

$$\begin{aligned} dA &= A_b(2, 5)db + A_h(2, 5)dh \\ &= \frac{5}{2}(0.05) + 1(0.1) \\ &= 0.225. \end{aligned}$$

So, the area of the triangle increases by $\boxed{\approx 0.225 \text{ cm}^2}$.

38. We approximate the change in the area of the triangle using the differential dA , where A is the area of the triangle. The formula for the area of a triangle of base b and height h is $A = \frac{1}{2}bh$. We compute the partial derivatives of A with respect to b and h at the point $(b, h) = (5, 10)$ in order to find the differential:

$$A_b(b, h) = \frac{1}{2}h$$

$$A_b(5, 10) = \frac{1}{2}(10) = 5$$

$$A_h(b, h) = \frac{1}{2}b$$

$$A_h(5, 10) = \frac{1}{2}(5) = \frac{5}{2}.$$

Also, $db = \Delta b = 5.1 - 5 = 0.1$ and $dh = \Delta h = 9.8 - 10 = -0.2$. The differential dA is then given by:

$$\begin{aligned} dA &= A_b(5, 10)db + A_h(5, 10)dh \\ &= 5(0.1) + \frac{5}{2}(-0.2) \\ &= 0. \end{aligned}$$

So, the area of the triangle changes by $\boxed{\approx 0 \text{ cm}^2}$, or essentially doesn't (or almost doesn't) change at all.

39. (a) We approximate the change in the volume of the right circular cylinder using the differential dV , where V is the volume of the cylinder. The formula for the volume of a right circular cylinder of

radius r and height h is $V = \pi r^2 h$. We compute the partial derivatives of V with respect to r and h at the point $(r, h) = (0.5, 2)$ in order to find the differential:

$$V_r(r, h) = 2\pi r h$$

$$V_r(0.5, 2) = 2\pi(0.5)(2) = 2\pi$$

$$V_h(r, h) = \pi r^2$$

$$V_h(0.5, 2) = \pi(0.5)^2 = \frac{\pi}{4}.$$

Also, $dr = \Delta r = 0.49 - 0.5 = -0.01$ and $dh = \Delta h = 2.1 - 2 = 0.1$. The differential dV is then given by:

$$\begin{aligned} dV &= V_r(0.5, 2)dr + V_h(0.5, 2)dh \\ &= 2\pi(-0.01) + \frac{\pi}{4}(0.1) \\ &= 0.005\pi \approx 0.016. \end{aligned}$$

So, the volume of the cylinder changes by $\boxed{\approx 0.016 \text{ cm}^3}$, which is a positive change, so the volume increases.

- (b) We approximate the change in the surface area of the right circular cylinder using the differential dA , where A is the surface area of the cylinder. The formula for the surface area of a closed right circular cylinder of radius r and height h is $V = 2\pi r h + 2\pi r^2$ (the first term is for the cylinder itself and the second for the two circles on top and bottom). We compute the partial derivatives of A with respect to r and h at the point $(r, h) = (0.5, 2)$ in order to find the differential:

$$A_r(r, h) = 2\pi h + 4\pi r$$

$$A_r(0.5, 2) = 2\pi(2) + 4\pi(0.5) = 6\pi$$

$$A_h(r, h) = 2\pi r$$

$$A_h(0.5, 2) = 2\pi(0.5) = \pi.$$

Also, $dr = \Delta r = 0.49 - 0.5 = -0.01$ and $dh = \Delta h = 2.1 - 2 = 0.1$, same as in part (a). The differential dA is then given by:

$$\begin{aligned} dA &= A_r(0.5, 2)dr + A_h(0.5, 2)dh \\ &= 6\pi(-0.01) + \pi(0.1) \\ &= 0.04\pi \approx 0.126. \end{aligned}$$

So, the surface area of the cylinder changes by $\boxed{\approx 0.126 \text{ cm}^2}$, which is a positive change, so the surface area increases.

40. We approximate the maximum variation of the total resistance R by using the differential dR . We first solve for R :

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2}$$

$$R = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2}} = \frac{R_1 R_2}{R_2 + R_1}$$

We will need the partial derivatives R_{R_1} and R_{R_2} :

$$R_{R_1} = \frac{R_2(R_2 + R_1) - R_1 R_2(1)}{(R_2 + R_1)^2} = \frac{R_2^2 + R_1 R_2 - R_1 R_2}{(R_2 + R_1)^2} = \frac{R_2^2}{(R_2 + R_1)^2}$$

and

$$R_{R_2} = \frac{R_1(R_2 + R_1) - R_1 R_2(1)}{(R_2 + R_1)^2} = \frac{R_1 R_2 + R_1^2 - R_1 R_2}{(R_2 + R_1)^2} = \frac{R_1^2}{(R_2 + R_1)^2}$$

Note also that $\frac{|\Delta R_1|}{R_1} = \frac{|dR_1|}{R_1} = 0.012$ and $\frac{|\Delta R_2|}{R_2} = \frac{|dR_2|}{R_2} = 0.01$

We have that $\frac{|\Delta R|}{R} \approx \frac{|dR|}{R} = \frac{\left| \frac{R_2^2}{(R_2 + R_1)^2} dR_1 + \frac{R_1^2}{(R_2 + R_1)^2} dR_2 \right|}{\frac{R_1 R_2}{R_2 + R_1}}$

$$\leq \frac{\left| \frac{R_2^2}{(R_2 + R_1)^2} dR_1 \right|}{\frac{R_1 R_2}{R_2 + R_1}} + \frac{\left| \frac{R_1^2}{(R_2 + R_1)^2} dR_2 \right|}{\frac{R_1 R_2}{R_2 + R_1}}$$

$$= \left| \frac{R_2 dR_1}{R_1(R_2 + R_1)} \right| + \left| \frac{R_1 dR_2}{R_2(R_2 + R_1)} \right|$$

$$\leq \left| \frac{dR_1}{R_1} \right| + \left| \frac{dR_2}{R_2} \right| \quad \text{since } 0 \leq \frac{R_2}{R_2 + R_1} \leq 1 \text{ and } 0 \leq \frac{R_1}{R_2 + R_1} \leq 1, \text{ since } R_1, R_2 \geq 0 \text{ always}$$

$$= 0.012 + 0.01 = 0.022. \text{ So, the maximum variation of the total resistance } R \text{ is } \boxed{\approx 2.2\%}$$

41. We find the differential ds .

$$\begin{aligned} \frac{\partial s}{\partial a} &= \frac{1(a-w) - a(1)}{(a-w)^2} = \frac{-w}{(a-w)^2} \\ \frac{\partial s}{\partial w} &= a[-(a-w)^{-2}(-1)] = \frac{a}{(a-w)^2} \\ ds &= \frac{\partial s}{\partial a} da + \frac{\partial s}{\partial w} dw = \frac{-w}{(a-w)^2} da + \frac{a}{(a-w)^2} dw \end{aligned}$$

We are told that a is subject to a possible error of 1%, and w is subject to a possible error of 2%. This means that

$$\frac{|\Delta a|}{a} = .01 \quad \text{and} \quad \frac{|\Delta w|}{w} = .02$$

We are also told that $s = 6$ and $w = 5$. Therefore, the relative error in the specific gravity s is:

$$\begin{aligned} \frac{|\Delta s|}{s} &\approx \frac{|ds|}{s} = \left| \frac{-w}{s(a-w)^2} da + \frac{a}{s(a-w)^2} dw \right| = \left| \frac{-w}{a(a-w)} da + \frac{1}{a-w} dw \right| \\ &= \left| \frac{-w}{a-w} \cdot \frac{da}{a} + \frac{w}{a-w} \cdot \frac{dw}{w} \right| = \left| \frac{-w}{a-w} \cdot \frac{\Delta a}{a} + \frac{w}{a-w} \cdot \frac{\Delta w}{w} \right| \\ &\leq \left| \frac{-w}{a-w} \right| \cdot \frac{|\Delta a|}{a} + \left| \frac{w}{a-w} \right| \cdot \frac{|\Delta w|}{w} = \frac{5}{1} \cdot (.01) + \frac{5}{1} \cdot (.02) = .15 \end{aligned}$$

So, the approximate maximum variation in the specific gravity s is $\boxed{\approx 15\%}$.

42. We can approximate the maximum variation in the volume of the silo by describing a function representing the volume V of the silo, and computing the differential dV . To find this function, we split the silo into two pieces: the bottom, cylindrical piece and the top, hemispherical piece. If the cylinder has radius r and height h , its volume is $V_{cyl} = \pi r^2 h$. The hemispherical piece must have the same radius as the cylinder, r , and the volume of a sphere with radius r is $\frac{4}{3}\pi r^3$, so the half-spherical portion has volume $V_{sph} = \frac{1}{2}[\frac{4}{3}\pi r^3] = \frac{2}{3}\pi r^3$. The volume of the silo is then the sum of these two: $V = \pi r^2 h + \frac{2}{3}\pi r^3$. The maximum relative error in the radius is $\frac{|\Delta r|}{r} = \frac{|dr|}{r} = 0.01$, as is the maximum relative error in the height, $\frac{|\Delta h|}{h} = \frac{|dh|}{h}$. The maximum relative error in the volume is $\frac{|\Delta V|}{V} \approx \frac{|dV|}{V}$.

We have

$$\begin{aligned} \frac{|\Delta V|}{V} &\approx \frac{|dV|}{V} = \frac{|(2\pi r h + 2\pi r^2)dr + \pi r^2 dh|}{\pi r^2 h + \frac{2}{3}\pi r^3} \\ &\leq \frac{|2\pi r h dr|}{\pi r^2 h + \frac{2}{3}\pi r^3} + \frac{|2\pi r^2 dr|}{\pi r^2 h + \frac{2}{3}\pi r^3} + \frac{|\pi r^2 dh|}{\pi r^2 h + \frac{2}{3}\pi r^3} \\ &\leq \frac{|2\pi r h dr|}{\pi r^2 h} + \frac{|2\pi r^2 dr|}{\frac{2}{3}\pi r^3} + \frac{|\pi r^2 dh|}{\pi r^2 h} \quad \text{since we decreased the denominators} \\ &= 2\frac{|dr|}{r} + 3\frac{|dr|}{r} + \frac{|dh|}{h} \\ &= 2(0.01) + 3(0.01) + 0.01 = 0.06 \end{aligned}$$

So, the maximum variation in the volume of the silo is 0.06, or $\boxed{\approx 6\%}$.

43. We find the differential $d\mu$.

$$\begin{aligned} \frac{\partial \mu}{\partial i} &= \frac{\cos i}{\sin r} \\ \frac{\partial \mu}{\partial r} &= \sin i \cdot \frac{\partial}{\partial r} ((\sin r)^{-1}) = \sin i \cdot (-1) \cdot (\sin r)^{-2} \cdot \frac{\partial}{\partial r} (\sin r) = -\frac{\sin i \cos r}{\sin^2 r} \\ d\mu &= \frac{\partial \mu}{\partial i} di + \frac{\partial \mu}{\partial r} dr = \frac{\cos i}{\sin r} di - \frac{\sin i \cos r}{\sin^2 r} dr \end{aligned}$$

We are told that each measurement is subject to a possible error of 2%. This means that

$$\frac{|\Delta i|}{i} = .02 \quad \text{and} \quad \frac{|\Delta r|}{r} = .02$$

We are also told that $i = 30^\circ$ and $r = 60^\circ$. Converting to radians, we have $i = \frac{\pi}{6}$ and $r = \frac{\pi}{3}$. Therefore,

the relative error in the index of refraction μ is

$$\begin{aligned}
\frac{|\Delta\mu|}{\mu} &\approx \frac{|d\mu|}{\mu} = \frac{\left| \frac{\cos i}{\sin r} di - \frac{\sin i \cos r}{\sin^2 r} dr \right|}{\frac{\sin i}{\sin r}} = \left| \frac{\cos i}{\sin i} di - \frac{\cos r}{\sin r} dr \right| \\
&= \left| \frac{i \cos i}{\sin i} \cdot \frac{di}{i} - \frac{r \cos r}{\sin r} \cdot \frac{dr}{r} \right| = \left| \frac{i \cos i}{\sin i} \cdot \frac{\Delta i}{i} - \frac{r \cos r}{\sin r} \cdot \frac{\Delta r}{r} \right| \\
&\leq \frac{i \cos i}{\sin i} \cdot \frac{|\Delta i|}{i} + \frac{r \cos r}{\sin r} \cdot \frac{|\Delta r|}{r} = \frac{\frac{\pi}{6} \cdot \cos\left(\frac{\pi}{6}\right)}{\sin\left(\frac{\pi}{6}\right)} \cdot (.02) + \frac{\frac{\pi}{3} \cdot \cos\left(\frac{\pi}{3}\right)}{\sin\left(\frac{\pi}{3}\right)} \cdot (.02) \\
&= \frac{\frac{\pi}{6} \cdot \frac{\sqrt{3}}{2}}{\frac{1}{2}} \cdot (.02) + \frac{\frac{\pi}{3} \cdot \frac{1}{2}}{\frac{\sqrt{3}}{2}} \cdot (.02) \approx .0302
\end{aligned}$$

So the approximate maximum relative error for μ is $\boxed{3.02\%}$.

44. For the ideal gas law, we recall (see problem 91 of section 2.4, on page 183) that T must be the *absolute* temperature, so we must convert the degrees Celsius into Kelvin. This is done by adding 273 to the degrees Celsius. So, we have $T = 32 + 273 = 305$. We write $P = \frac{kT}{V} = kTV^{-1}$ and we find the differential dP .

$$\begin{aligned}
\frac{\partial P}{\partial V} &= kT \cdot (-1) \cdot V^{-2} = -\frac{kT}{V^2} \\
\frac{\partial P}{\partial T} &= \frac{k}{V} \\
dP &= \frac{\partial P}{\partial V} dV + \frac{\partial P}{\partial T} dT = -\frac{kT}{V^2} dV + \frac{k}{V} dT
\end{aligned}$$

Now we know that

$$P = 0.1, V = 12, T = 305; \quad \Delta V = 3, \Delta T = -3.$$

We now have the necessary information to compute k :

$$k = \frac{PV}{T} = \frac{(0.1)(12)}{305} \approx 0.0039344.$$

Therefore,

$$\begin{aligned}
\Delta P &\approx dP = -\frac{kT}{V^2} dV + \frac{k}{V} dT = -\frac{kT\Delta V}{V^2} + \frac{k\Delta T}{V} = \frac{k(V\Delta T - T\Delta V)}{V^2} \\
&= \frac{(0.0039344)((12)(-3) - (305)(3))}{(12)^2} \approx -0.026
\end{aligned}$$

So, $\boxed{\Delta P \approx -0.026 \text{ g/mm}^2}$.

45. (a) We know that the volume of a spherical object with radius r is $V = \frac{4\pi r^3}{3}$. Substituting $r = \frac{d}{2}$, we get $V = \frac{\pi d^3}{6}$. The average density of the object is mass per unit volume, so $\rho = \frac{m}{V} = \frac{6m}{\pi d^3} = \frac{6}{\pi}md^{-3}$. Now we need to find the differential $d\rho$.

$$\begin{aligned}
\frac{\partial \rho}{\partial m} &= \frac{6}{\pi d^3} \\
\frac{\partial \rho}{\partial d} &= \frac{6}{\pi} \cdot m(-3d^{-4}) = -\frac{18m}{\pi d^4} \\
d\rho &= \frac{\partial \rho}{\partial m} dm + \frac{\partial \rho}{\partial d} dd = \frac{6}{\pi d^3} dm - \frac{18m}{\pi d^4} dd
\end{aligned}$$

We also know that

$$m = 24, d = 1.5; \quad |\Delta m| = 0.24, |\Delta d| = 0.075.$$

Therefore, the approximate maximum error in the average density ρ is

$$\begin{aligned} |\Delta \rho| &\approx |d\rho| = \left| \frac{6}{\pi d^3} dm - \frac{18m}{\pi d^4} dd \right| = \left| \frac{6\Delta m}{\pi d^3} - \frac{18m\Delta d}{\pi d^4} \right| \\ &\leq \left| \frac{6\Delta m}{\pi d^3} \right| + \left| \frac{18m\Delta d}{\pi d^4} \right| = \frac{6}{\pi d^3} |\Delta m| + \frac{18m}{\pi d^4} |\Delta d| \\ &= \frac{6}{(1.5)^3 \pi} (0.24) + \frac{(18)(24)}{(1.5)^4 \pi} (0.075) \approx 2.173 \end{aligned}$$

So the approximate maximum error for ρ is $\boxed{2.173 \text{ g/cm}^3}$.

(b) We compute the density ρ for the given values, $m = 24.0$ and $d = 1.5$:

$$\rho = \frac{6m}{\pi d^3} = \frac{(6)(24.0)}{(1.5)^3 \pi} \approx 13.581 \text{ g/cm}^3,$$

and therefore

$$\frac{|\Delta \rho|}{\rho} = \frac{|d\rho|}{\rho} \leq \frac{2.173}{13.581} \approx 0.16000.$$

So the approximate maximum percentage error in the computed density is $\boxed{16\%}$.

46. (a) We find the differential dA .

$$\begin{aligned} \frac{\partial A}{\partial b} &= \frac{1}{2} c \sin \alpha \\ \frac{\partial A}{\partial c} &= \frac{1}{2} b \sin \alpha \\ \frac{\partial A}{\partial \alpha} &= \frac{1}{2} bc \cos \alpha \\ dA &= \frac{\partial A}{\partial b} db + \frac{\partial A}{\partial c} dc + \frac{\partial A}{\partial \alpha} d\alpha = \frac{1}{2} (c \sin \alpha db + b \sin \alpha dc + bc \cos \alpha d\alpha). \end{aligned}$$

Therefore,

$$\begin{aligned} \frac{dA}{A} &= \frac{1}{2A} (c \sin \alpha db + b \sin \alpha dc + bc \cos \alpha d\alpha) \\ &= \frac{1}{bc \sin \alpha} (c \sin \alpha db + b \sin \alpha dc + bc \cos \alpha d\alpha) \\ &= \frac{db}{b} + \frac{dc}{c} + \frac{\cos \alpha d\alpha}{\sin \alpha} \\ &= \frac{db}{b} + \frac{dc}{c} + \cot \alpha d\alpha. \end{aligned}$$

(b) We are told that

$$\frac{|\Delta b|}{b} = 0.02, \frac{|\Delta c|}{c} = 0.02, \frac{|\Delta \alpha|}{\alpha} = 0.03, \alpha = \frac{\pi}{4}, \text{ and so } \cot \alpha = 1.$$

Therefore,

$$\begin{aligned} \frac{|\Delta A|}{A} &\approx \frac{|dA|}{A} = \left| \frac{db}{b} + \frac{dc}{c} + \cot \alpha d\alpha \right| \\ &= \left| \frac{\Delta b}{b} + \frac{\Delta c}{c} + \cot \alpha \Delta \alpha \right| \leq \frac{|\Delta b|}{b} + \frac{|\Delta c|}{c} + \cot \alpha |\Delta \alpha| \\ &= \frac{|\Delta b|}{b} + \frac{|\Delta c|}{c} + \alpha \cot \alpha \frac{|\Delta \alpha|}{\alpha} = 0.02 + 0.02 + \left(\frac{\pi}{4} \right) \cdot 1 \cdot (0.03) \approx 0.06356. \end{aligned}$$

So, the approximate maximum relative variation in the computation of A is 6.356%.

47. (a)

$$\begin{aligned} f_x(x, y) &= \frac{\partial}{\partial x} \left((x^2 + y^2 - 2x - 6y + 10)^{1/2} \right) \\ &= \frac{1}{2} (x^2 + y^2 - 2x - 6y + 10)^{-1/2} \cdot \frac{\partial}{\partial x} (x^2 + y^2 - 2x - 6y + 10) \\ &= \frac{x - 1}{\sqrt{x^2 + y^2 - 2x - 6y + 10}} \end{aligned}$$

$$f_x(x, y) = \frac{x - 1}{\sqrt{x^2 + y^2 - 2x - 6y + 10}}$$

$$\begin{aligned} f_y(x, y) &= \frac{\partial}{\partial y} \left((x^2 + y^2 - 2x - 6y + 10)^{1/2} \right) \\ &= \frac{1}{2} (x^2 + y^2 - 2x - 6y + 10)^{-1/2} \cdot \frac{\partial}{\partial y} (x^2 + y^2 - 2x - 6y + 10) \\ &= \frac{y - 3}{\sqrt{x^2 + y^2 - 2x - 6y + 10}} \end{aligned}$$

$$f_y(x, y) = \frac{y - 3}{\sqrt{x^2 + y^2 - 2x - 6y + 10}}$$

- (b) We look at the expression $x^2 + y^2 - 2x - 6y + 10$, which appears under the radical in the denominator. The partial derivatives will be continuous at all points (x, y) for which this expression is positive. We complete the square:

$$x^2 + y^2 - 2x - 6y + 10 = x^2 - 2x + 1 + y^2 - 6y + 9 = (x - 1)^2 + (y - 3)^2$$

This is a sum of two squares, so it is always positive, except when $x - 1$ and $y - 3$ are both zero. So,

the partial derivatives are continuous everywhere in the xy -plane, except at the point $(1, 3)$.

- (c) The graph is the following:

- (d) The partial derivatives are discontinuous at the point $(1, 3)$ because that is where the vertex of the graph (a circular cone) is located.

48. We compute the differentials dx and dy :

$$\begin{aligned}\frac{\partial x}{\partial r} &= \cos \theta \\ \frac{\partial x}{\partial \theta} &= -r \sin \theta \\ \frac{\partial y}{\partial r} &= \sin \theta \\ \frac{\partial y}{\partial \theta} &= r \cos \theta\end{aligned}$$

$$\begin{aligned}dx &= \cos \theta dr - r \sin \theta d\theta \\ dy &= \sin \theta dr + r \cos \theta d\theta\end{aligned}$$

Therefore,

$$\begin{aligned}x dy - y dx &= x \sin \theta dr + xr \cos \theta d\theta - y \cos \theta dr + yr \sin \theta d\theta \\ &= x \sin \theta dr + x^2 d\theta - y \cos \theta dr + y^2 d\theta \\ &= x \sin \theta dr - y \cos \theta dr + (x^2 + y^2) d\theta \\ &= x \cdot \frac{y}{r} dr - y \cdot \frac{x}{r} dr + r^2 d\theta = \left(\frac{xy}{r} - \frac{xy}{r} \right) dr + r^2 d\theta = r^2 d\theta.\end{aligned}$$

49.

$$\begin{aligned}f_x(0, 0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\frac{2 \cdot \Delta x \cdot 0}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} = \lim_{\Delta x \rightarrow 0} 0 = 0 \\ f_y(0, 0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} \\ &= \lim_{\Delta y \rightarrow 0} \frac{\frac{2 \cdot 0 \cdot \Delta y}{0 + (\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} 0 = 0\end{aligned}$$

Therefore, f has partial derivatives at $(0, 0)$. To determine whether f is continuous at $(0, 0)$, we need to determine whether $\lim_{(x, y) \rightarrow (0, 0)} f(x, y)$ exists and equals $f(0, 0)$. We investigate the limit using two curves that contain $(0, 0)$: the x -axis ($y = 0$) and the line $y = x$. Using $y = 0$:

$$\lim_{(x, y) \rightarrow (0, 0)} \frac{2x \cdot 0}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{0}{x^2} = \lim_{x \rightarrow 0} 0 = 0.$$

Using $y = x$:

$$\lim_{(x, y) \rightarrow (0, 0)} \frac{2x \cdot x}{x^2 + x^2} = \lim_{x \rightarrow 0} \frac{2x^2}{2x^2} = \lim_{x \rightarrow 0} 1 = 1.$$

Since two different answers are obtained, the limit $\lim_{(x, y) \rightarrow (0, 0)} f(x, y)$ does not exist. Therefore, f cannot be continuous at $(0, 0)$. But we know that if f is differentiable at $(0, 0)$, then f must be continuous at $(0, 0)$. (“Differentiability is Sufficient for Continuity”, page 845) Since f is not continuous at $(0, 0)$, we conclude that f is **not** differentiable at $(0, 0)$.

50.

$$\begin{aligned}
f_x(0,0) &= \lim_{\Delta x \rightarrow 0} \frac{f(0 + \Delta x, 0) - f(0,0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0,0)}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{\Delta x \cdot 0 \cdot (1+0)}{(\Delta x)^2 + 0} - 0}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} = \lim_{\Delta x \rightarrow 0} 0 = 0 \\
f_y(0,0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, 0 + \Delta y) - f(0,0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0,0)}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{0 \cdot \Delta y \cdot (1+(\Delta y)^2)}{0+(\Delta y)^2} - 0}{\Delta y} = \lim_{\Delta y \rightarrow 0} 0 = 0
\end{aligned}$$

Therefore, f has partial derivatives at $(0,0)$. To determine whether f is continuous at $(0,0)$, we need to determine whether $\lim_{(x,y) \rightarrow (0,0)} f(x,y)$ exists and equals $f(0,0)$. We investigate the limit using two curves that contain $(0,0)$: the x -axis ($y = 0$) and the line $y = x$. Using $y = 0$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x \cdot 0 \cdot (1+0)}{x^2 + 0} = \lim_{x \rightarrow 0} \frac{0}{x^2} = \lim_{x \rightarrow 0} 0 = 0.$$

Using $y = x$:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x \cdot x \cdot (1+x^2)}{x^2 + x^2} = \lim_{x \rightarrow 0} \frac{x^2 + x^4}{2x^2} = \lim_{x \rightarrow 0} \frac{x^2(1+x^2)}{2x^2} = \lim_{x \rightarrow 0} \frac{1+x^2}{2} = \frac{1}{2}.$$

Since two different answers are obtained, the limit $\lim_{(x,y) \rightarrow (0,0)} f(x,y)$ does not exist. Therefore, f cannot be continuous at $(0,0)$. But we know that if f is differentiable at $(0,0)$, then f must be continuous at $(0,0)$. (“Differentiability is Sufficient for Continuity”, page 845) Since f is not continuous at $(0,0)$, we conclude that f is **not** differentiable at $(0,0)$.

51. We compute f_x and f_y at $(1,1)$ by using the definition of a partial derivative:

$$\begin{aligned}
f_x(1,1) &= \lim_{\Delta x \rightarrow 0} \frac{f(1 + \Delta x, 1) - f(1,1)}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{(1+\Delta x)(1)-1}{(1+\Delta x)^2 + 1^2 - 2} - \frac{1}{2}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{1+\Delta x-1}{1+2\Delta x+(\Delta x)^2-1} - \frac{1}{2}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{\Delta x}{2\Delta x+(\Delta x)^2} - \frac{1}{2}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{\Delta x}{\Delta x(2+\Delta x)} - \frac{1}{2}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{1}{2+\Delta x} - \frac{1}{2}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{2-(2+\Delta x)}{2(2+\Delta x)}}{\Delta x}
\end{aligned}$$

$$\begin{aligned}
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{-\Delta x}{2(2+\Delta x)}}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{-\Delta x}{2(2+\Delta x)} \cdot \frac{1}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{-1}{2(2+\Delta x)} \\
&= -\frac{1}{4}
\end{aligned}$$

and

$$\begin{aligned}
f_y(1,1) &= \lim_{\Delta y \rightarrow 0} \frac{f(1,1+\Delta y) - f(1,1)}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{(1)(1+\Delta y)-1}{1^2+(1+\Delta y)^2-2} - \frac{1}{2}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{1+\Delta y-1}{1+1+2\Delta y+(\Delta y)^2-2} - \frac{1}{2}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{\Delta y}{2\Delta y+(\Delta y)^2} - \frac{1}{2}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{\Delta y}{\Delta y(2+\Delta y)} - \frac{1}{2}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{1}{2+\Delta y} - \frac{1}{2}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{2-(2+\Delta y)}{2(2+\Delta y)}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{-\Delta y}{2(2+\Delta y)}}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{-\Delta y}{2(2+\Delta y)} \cdot \frac{1}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{-1}{2(2+\Delta y)} \\
&= -\frac{1}{4}
\end{aligned}$$

So $f_x(1,1)$ and $f_y(1,1)$ both exist (and equal $-\frac{1}{4}$). But, we can see that f is in fact not continuous and so not differentiable, since if a function is differentiable it is continuous. We see this by showing that $\lim_{(x,y) \rightarrow (1,1)} f(x,y)$ does not exist. We do so by computing the limit along two different curves containing $(1,1)$ and showing that we obtain different values:

Along $y = 1$:

$$\begin{aligned}
\lim_{(x,y) \rightarrow (1,1)} \frac{xy-1}{x^2+y^2-2} &= \lim_{x \rightarrow 1} \frac{x(1)-1}{x^2+1^2-2} = \lim_{x \rightarrow 1} \frac{x-1}{x^2-1} \\
&= \lim_{x \rightarrow 1} \frac{x-1}{(x-1)(x+1)} \\
&= \lim_{x \rightarrow 1} \frac{1}{x+1} \\
&= \frac{1}{2}
\end{aligned}$$

Along $y = 2 - x$:

$$\begin{aligned}
\lim_{(x,y) \rightarrow (1,1)} \frac{xy-1}{x^2+y^2-2} &= \lim_{x \rightarrow 1} \frac{x(2-x)-1}{x^2+(2-x)^2-2} = \lim_{x \rightarrow 1} \frac{2x-x^2-1}{x^2+4-4x+x^2-2} \\
&= \lim_{x \rightarrow 1} \frac{-(x^2-2x+1)}{2x^2-4x+2} \\
&= \lim_{x \rightarrow 1} \frac{-(x^2-2x+1)}{2(x^2-2x+1)} \\
&= \lim_{x \rightarrow 1} \frac{-1}{2} \\
&= -\frac{1}{2}
\end{aligned}$$

Since these two limits are not equal, the limit does not exist, which means that f cannot be continuous at $(1,1)$ and so is not differentiable at $(1,1)$.

52. We compute f_x and f_y at $(0,0)$ by using the definition of a partial derivative:

$$\begin{aligned}
f_x(0,0) &= \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0,0)}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{\frac{(\Delta x)^2(0)^2}{(\Delta x)^4+0^4} - 0}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} \frac{0}{\Delta x} \\
&= \lim_{\Delta x \rightarrow 0} 0 = 0
\end{aligned}$$

and

$$\begin{aligned}
f_y(0,0) &= \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0,0)}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{\frac{(0)^2(\Delta y)^2}{0^4+(\Delta y)^4} - 0}{\Delta y} \\
&= \lim_{\Delta y \rightarrow 0} \frac{0}{\Delta y}
\end{aligned}$$

$$= \lim_{\Delta y \rightarrow 0} 0 = 0$$

So, both $f_x(0,0)$ and $f_y(0,0)$ exist (and equal 0). But, we can see that f is in fact not continuous and so not differentiable, since if a function is differentiable it is continuous. We see this by showing that

$\lim_{(x,y) \rightarrow (0,0)} f(x,y)$ does not exist. We do so by computing the limit along two different curves containing $(0,0)$ and showing that we obtain different values:

Along $y = 0$:

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{x^2 y^2}{x^4 + y^4} &= \lim_{x \rightarrow 0} \frac{x^2 (0^2)}{x^4 + 0^4} \\ &= \lim_{x \rightarrow 0} 0 = 0 \end{aligned}$$

Along $y = x$:

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{x^2 y^2}{x^4 + y^4} &= \lim_{x \rightarrow 0} \frac{x^2 (x^2)}{x^4 + x^4} \\ &= \lim_{x \rightarrow 0} \frac{x^4}{2x^4} \\ &= \lim_{x \rightarrow 0} \frac{1}{2} = \frac{1}{2} \end{aligned}$$

Since these two limits are not equal, the limit does not exist, which means that f cannot be continuous at $(0,0)$ and so is not differentiable at $(0,0)$.

Challenge Problems

53. (a) We have that $R = \frac{\rho L}{\pi r^2} = \frac{1}{\pi} \rho L r^{-2}$. We compute the partial derivatives of R with respect to ρ , L and r :

$$\begin{aligned} \frac{\partial R}{\partial \rho} &= \frac{1}{\pi} L r^{-2} \\ \frac{\partial R}{\partial L} &= \frac{1}{\pi} \rho r^{-2} \\ \frac{\partial R}{\partial r} &= \frac{-2}{\pi} \rho L r^{-3} \end{aligned}$$

So,

$$\begin{aligned} dR &= \frac{\partial R}{\partial \rho} d\rho + \frac{\partial R}{\partial L} dL + \frac{\partial R}{\partial r} dr = \frac{1}{\pi} (L r^{-2} d\rho + \rho r^{-2} dL - 2\rho L r^{-3} dr) \\ &= \frac{1}{\pi} (L r^{-2} \Delta\rho + \rho r^{-2} \Delta L - 2\rho L r^{-3} \Delta r) \\ &= \frac{1}{\pi} (L r^{-2} \rho_0 K \Delta T + \rho r^{-2} L_0 \alpha \Delta T - 2\rho L r^{-3} r_0 \alpha \Delta T) \end{aligned}$$

When $\rho = \rho_0$, $L = L_0$ and $r = r_0$, this gives

$$dR = \frac{1}{\pi} \rho_0 L_0 r_0^{-2} \Delta T (K + \alpha - 2\alpha) = R_0 \Delta T (K - \alpha),$$

where R_0 is the initial resistance. But we are given that $R_0 = 0.50$ and $\Delta T = 40$, so

$$\Delta R \approx dR = 0.50 \cdot 40 \cdot (K - \alpha) = 0.50 \cdot 40 \cdot (3.93 \times 10^{-3} - 5.1 \times 10^{-5}) = 0.07758.$$

So, the resistance of the wire at 40°C is $R_0 + \Delta R \approx 0.578 \Omega$.

(b)

$$\frac{|\Delta R|}{R_0} \approx \frac{0.07758}{0.50} = 0.15516,$$

so the percent change in the resistance of the wire is approximately 15.516% .

(c) The change in resistance caused by the increase in the resistivity is:

$$\frac{\partial R}{\partial \rho} d\rho = \frac{1}{\pi} L r^{-2} \Delta \rho = \frac{1}{\pi} L r^{-2} \rho_0 K \Delta T$$

When $L = L_0$ and $r = r_0$, this gives

$$\begin{aligned} \frac{\partial R}{\partial \rho} d\rho &= \frac{1}{\pi} \rho_0 L_0 r_0^{-2} \Delta T \cdot K = R_0 K \Delta T \\ &= (0.50) \cdot (3.93 \times 10^{-3}) \cdot (40) = 0.0786 \Omega \end{aligned}$$

The change in resistance caused by the expansion of the wire is:

$$\begin{aligned} \frac{\partial R}{\partial L} dL + \frac{\partial R}{\partial r} dr &= \frac{1}{\pi} (\rho r^{-2} dL - 2\rho L r^{-3} dr) = \frac{1}{\pi} (\rho r^{-2} \Delta L - 2\rho L r^{-2} \Delta r) \\ &= \frac{1}{\pi} (\rho r^{-2} L_0 \alpha \Delta T - 2\rho L r^{-3} r_0 \alpha \Delta T) \end{aligned}$$

When $\rho = \rho_0$, $L = L_0$ and $r = r_0$,

$$\begin{aligned} &= \frac{1}{\pi} \rho_0 L_0 r_0^{-2} \Delta T (\alpha - 2\alpha) \\ &= -R_0 \alpha \Delta T = -(0.50) \cdot (5.1 \times 10^{-5}) \cdot 40 = -0.00102 \Omega \end{aligned}$$

Since the absolute value of the first is greater than the absolute value of the second, we conclude that the increase in the resistivity contributes more to the change in resistance.

54. (a) The differential of the function $w = f(x, y, z) = x^{y^z}$ is $dw = f_x dx + f_y dy + f_z dz$. We compute the required partial derivatives:

$$f_x = y^z x^{y^z-1}$$

$$f_y = (\ln x) x^{y^z} (z y^{z-1})$$

$$f_z = (\ln x) x^{y^z} (\ln y) y^z$$

So, the differential is $dw = y^z x^{y^z-1} dx + (\ln x) x^{y^z} (z y^{z-1}) dy + (\ln x) x^{y^z} (\ln y) y^z dz$.

- (b) The differential of the function $w = g(x, y, z) = (x^y)^z$ is $dw = g_x dx + g_y dy + g_z dz$. We compute the required partial derivatives, by first noting that $w = g(x, y, z) = (x^y)^z = x^{yz}$ by rules of exponents:

$$g_x = yz x^{yz-1}$$

$$g_y = (\ln x) x^{yz} (z) = z(\ln x) x^{yz}$$

$$g_z = (\ln x) x^{yz} (y) = y(\ln x) x^{yz}$$

So, the differential is $\boxed{dw = yz x^{yz-1} dx + z(\ln x) x^{yz} dy + y(\ln x) x^{yz} dz}$.

Chapter 12: Functions of Several Variables

12.5 Chain Rules

Concepts and Vocabulary

1. False. The formula is missing a minus sign; it should be $\frac{\partial z}{\partial x} = -\frac{F_x(x, y, z)}{F_z(x, y, z)}$. See the Implicit Differentiation Formulas II, on page 855.
2. False. Each term of the formula is missing a factor; it should be $\frac{dz}{dt} = \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt}$. See Chain Rule I for One Independent Variable, on page 849.

Skill Building

3.

$$\frac{\partial z}{\partial x} = 2x$$

$$\frac{\partial z}{\partial y} = 2y$$

$$\frac{dx}{dt} = \cos t$$

$$\frac{dy}{dt} = -\sin(2t) \cdot \frac{d}{dt}(2t) = -\sin(2t) \cdot 2 = -2\sin(2t)$$

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt} = 2x \cos t - 4y \sin(2t) = 2 \sin t \cos t - 4 \cos(2t) \sin(2t)$$

$$\boxed{\frac{dz}{dt} = 2x \cos t - 4y \sin(2t) = 2 \sin t \cos t - 4 \cos(2t) \sin(2t)}$$

4.

$$\begin{aligned}
\frac{\partial z}{\partial x} &= 2x \\
\frac{\partial z}{\partial y} &= -2y \\
\frac{dx}{dt} &= \cos(2t) \cdot \frac{d}{dt}(2t) = \cos(2t) \cdot 2 = 2\cos(2t) \\
\frac{dy}{dt} &= -\sin t \\
\frac{dz}{dt} &= \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt} = 4x \cos(2t) + 2y \sin t = 4 \sin(2t) \cos(2t) + 2 \cos t \sin t
\end{aligned}$$

$$\boxed{\frac{dz}{dt} = 4x \cos(2t) + 2y \sin t = 4 \sin(2t) \cos(2t) + 2 \sin t \cos t}$$

5.

$$\begin{aligned}
\frac{\partial z}{\partial x} &= 2x \\
\frac{\partial z}{\partial y} &= 2y \\
\frac{dx}{dt} &= \frac{d}{dt}(te^t) = \frac{d}{dt}(t) \cdot e^t + t \cdot \frac{d}{dt}(e^t) = e^t + te^t \\
\frac{dy}{dt} &= \frac{d}{dt}(te^{-t}) = \frac{d}{dt}(t) \cdot e^{-t} + t \cdot \frac{d}{dt}(e^{-t}) = e^{-t} + t \cdot e^{-t} \cdot \frac{d}{dt}(-t) = e^{-t} - t \cdot e^{-t} \\
\frac{dz}{dt} &= \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt} = 2x(e^t + te^t) + 2y(e^{-t} - t \cdot e^{-t}) \\
&= 2te^t(e^t + te^t) + 2te^{-t}(e^{-t} - t \cdot e^{-t}) = 2te^{2t} + 2t^2e^{2t} + 2te^{-2t} - 2t^2e^{-2t}
\end{aligned}$$

$$\boxed{\frac{dz}{dt} = 2x(e^t + te^t) + 2y(e^{-t} - t \cdot e^{-t}) = 2te^{2t} + 2t^2e^{2t} + 2te^{-2t} - 2t^2e^{-2t}}$$

6.

$$\begin{aligned}
\frac{\partial z}{\partial x} &= 2x \\
\frac{\partial z}{\partial y} &= -2y \\
\frac{dx}{dt} &= \frac{d}{dt}(te^{-t}) = \frac{d}{dt}(t) \cdot e^{-t} + t \cdot \frac{d}{dt}(e^{-t}) = e^{-t} + t \cdot e^{-t} \cdot \frac{d}{dt}(-t) = e^{-t} - te^{-t} \\
\frac{dy}{dt} &= \frac{d}{dt}(t^2e^{-t}) = \frac{d}{dt}(t^2) \cdot e^{-t} + t^2 \cdot \frac{d}{dt}(e^{-t}) = 2te^{-t} + t^2 \cdot e^{-t} \cdot \frac{d}{dt}(-t) = 2te^{-t} - t^2e^{-t} \\
\frac{dz}{dt} &= \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt} = 2x(e^{-t} - te^{-t}) - 2y(2te^{-t} - t^2e^{-t}) \\
&= 2te^{-t}(e^{-t} - te^{-t}) - 2t^2e^{-t}(2te^{-t} - t^2e^{-t}) = 2te^{-2t} - 2t^2e^{-2t} - 4t^3e^{-2t} + 2t^4e^{-2t}
\end{aligned}$$

$$\boxed{\frac{dz}{dt} = 2x(e^{-t} - te^{-t}) - 2y(2te^{-t} - t^2e^{-t}) = 2te^{-2t} - 2t^2e^{-2t} - 4t^3e^{-2t} + 2t^4e^{-2t}}$$

7.

$$\begin{aligned}
\frac{\partial z}{\partial u} &= e^u \sin v \\
\frac{\partial z}{\partial v} &= e^u \cos v \\
\frac{du}{dt} &= \frac{d}{dt} \left(t^{1/2} \right) = \frac{1}{2} t^{-1/2} \\
\frac{dv}{dt} &= \pi \\
\frac{dz}{dt} &= \frac{\partial z}{\partial u} \frac{du}{dt} + \frac{\partial z}{\partial v} \frac{dv}{dt} = e^u \sin v \cdot \frac{1}{2} t^{-1/2} + e^u \cos v \cdot \pi \\
&= \frac{1}{2\sqrt{t}} e^{\sqrt{t}} \sin(\pi t) + \pi e^{\sqrt{t}} \cos(\pi t)
\end{aligned}$$

$$\boxed{\frac{dz}{dt} = \frac{e^u \sin v}{2\sqrt{t}} + \pi e^u \cos v = \frac{e^{\sqrt{t}} \sin(\pi t)}{2\sqrt{t}} + \pi e^{\sqrt{t}} \cos(\pi t)}$$

8.

$$\begin{aligned}
\frac{\partial z}{\partial u} &= e^{u/v} \frac{\partial}{\partial u} \left(\frac{u}{v} \right) = e^{u/v} \frac{1}{v} \\
\frac{\partial z}{\partial v} &= e^{u/v} \frac{\partial}{\partial v} \left(\frac{u}{v} \right) = e^{u/v} \frac{\partial}{\partial v} (uv^{-1}) = e^{u/v} (-uv^{-2}) \\
\frac{du}{dt} &= \frac{d}{dt} \left(t^{1/2} \right) = \frac{1}{2} t^{-1/2} \\

$$\boxed{\frac{\partial z}{\partial x} = \frac{-(z + 2xy^3)}{x + 6yz - 5}}$$

$$\boxed{\frac{\partial z}{\partial y} = \frac{-(3z^2 + 3x^2y^2)}{x + 6yz - 5}}$$

48. First, we find the partial derivatives of F :

$$F_x = 2xz + 3x^2y, F_y = 2yz + x^3 \text{ and } F_z = x^2 + y^2 - 10.$$

Then we use Implicit Differentiation Formulas II. If $x^2 + y^2 - 10 \neq 0$,

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{2xz + 3x^2y}{x^2 + y^2 - 10}$$

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{2yz + x^3}{x^2 + y^2 - 10}$$

$$\frac{\partial z}{\partial x} = \frac{-(2xz + 3x^2y)}{x^2 + y^2 - 10}$$

$$\frac{\partial z}{\partial y} = \frac{-(2yz + x^3)}{x^2 + y^2 - 10}$$

49. First, we find the partial derivatives of F :

$$F_x = yz, F_y = \cos z + xz \text{ and } F_z = \cos z - y \sin z + xy.$$

Then we use Implicit Differentiation Formulas II. If $\cos z - y \sin z + xy \neq 0$,

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{yz}{\cos z - y \sin z + xy}$$

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{\cos z + xz}{\cos z - y \sin z + xy}$$

$$\frac{\partial z}{\partial x} = \frac{-yz}{\cos z - y \sin z + xy}$$

$$\frac{\partial z}{\partial y} = \frac{-(\cos z + xz)}{\cos z - y \sin z + xy}$$

50. First, we find the partial derivatives of F :

$$F_x = \sin y + 2xz, F_y = x \cos y \text{ and } F_z = \sin z + x^2.$$

Then we use Implicit Differentiation Formulas II. If $\sin z + x^2 \neq 0$,

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{\sin y + 2xz}{\sin z + x^2}$$

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{x \cos y}{\sin z + x^2}$$

$$\frac{\partial z}{\partial x} = \frac{-(\sin y + 2xz)}{\sin z + x^2}$$

$$\frac{\partial z}{\partial y} = \frac{-x \cos y}{\sin z + x^2}$$

51. First, we find the partial derivatives of F :

$$F_x = e^{yz} + yze^{xz} + yz, F_y = xze^{yz} + e^{xz} + xz \text{ and } F_z = xye^{yz} + xye^{xz} + xy.$$

Then we use Implicit Differentiation Formulas II. If $xye^{yz} + xye^{xz} + xy \neq 0$,

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{e^{yz} + yze^{xz} + yz}{xye^{yz} + xye^{xz} + xy}$$

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{xze^{yz} + e^{xz} + xz}{xye^{yz} + xye^{xz} + xy}$$

$$\frac{\partial z}{\partial x} = \frac{-(e^{yz} + yze^{xz} + yz)}{xye^{yz} + xye^{xz} + xy}$$

$$\frac{\partial z}{\partial y} = \frac{-(xze^{yz} + e^{xz} + xz)}{xye^{yz} + xye^{xz} + xy}$$

52. First, we find the partial derivatives of F :

$$F_x = \frac{e^{yz}}{x} + yze^{xz}, F_y = ze^{yz} \ln x + e^{xz} - z \text{ and } F_z = ye^{yz} \ln x + xye^{xz} - y.$$

Then we use Implicit Differentiation Formulas II. If $ye^{yz} \ln x + xye^{xz} - y \neq 0$,

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{\frac{e^{yz}}{x} + yze^{xz}}{ye^{yz} \ln x + xye^{xz} - y} = -\frac{e^{yz} + xye^{xz}}{xye^{yz} \ln x + x^2ye^{xz} - xy}$$

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{ze^{yz} \ln x + e^{xz} - z}{ye^{yz} \ln x + xye^{xz} - y}$$

$$\frac{\partial z}{\partial x} = \frac{-(e^{yz} + xye^{xz})}{xye^{yz} \ln x + x^2ye^{xz} - xy}$$

$$\frac{\partial z}{\partial y} = \frac{-(ze^{yz} \ln x + e^{xz} - z)}{ye^{yz} \ln x + xye^{xz} - y}$$

53. Recall that to find $\frac{\partial w}{\partial x}$, we treat y and z as constants. This allows to use the power rule (along with the chain rule).

$$\frac{\partial w}{\partial x} = (4z)(2x + 3y)^{4z-1}(2) = 8z(2x + 3y)^{4z-1}$$

To find $\frac{\partial w}{\partial y}$, we treat x and z as constants. This allows to again use the power rule (along with the chain rule).

$$\frac{\partial w}{\partial y} = (4z)(2x + 3y)^{4z-1}(3) = 12z(2x + 3y)^{4z-1}$$

Lastly, to find $\frac{\partial w}{\partial z}$, we treat x and y as constants. We then use the rule for exponential functions,

$$\frac{d}{dx}[a^x] = a^x \ln a \text{ (along with the chain rule).}$$

$$\frac{\partial w}{\partial z} = (2x + 3y)^{4z} \ln(2x + 3y) \cdot 4 = 4(2x + 3y)^{4z} \ln(2x + 3y).$$

$$\frac{\partial w}{\partial x} = 8z(2x + 3y)^{4z-1}$$

$$\frac{\partial w}{\partial y} = 12z(2x + 3y)^{4z-1}$$

$$\frac{\partial w}{\partial z} = 4(2x + 3y)^{4z} \ln(2x + 3y)$$

54. Recall that to find $\frac{\partial w}{\partial x}$, we treat y and z as constants. This allows to use the power rule (along with the chain rule).

$$\frac{\partial w}{\partial x} = (3y + 4z)(2x)^{3y+4z-1}(2) = 2(3y + 4z)(2x)^{3y+4z-1}$$

To find $\frac{\partial w}{\partial y}$, we treat x and z as constants. We then use the rule for exponential functions, $\frac{d}{dx}[a^x] = a^x \ln a$ (along with the chain rule).

$$\frac{\partial w}{\partial y} = (2x)^{3y+4z} \ln(2x) \cdot 3 = 3(2x)^{3y+4z} \ln(2x)$$

Lastly, to find $\frac{\partial w}{\partial z}$, we treat x and y as constants. We again use the rule for exponential functions, $\frac{d}{dx}[a^x] = a^x \ln a$ (along with the chain rule).

$$\frac{\partial w}{\partial z} = (2x)^{3y+4z} \ln(2x) \cdot 4 = 4(2x)^{3y+4z} \ln(2x).$$

$$\frac{\partial w}{\partial x} = 2(3y + 4z)(2x)^{3y+4z-1}$$

$$\frac{\partial w}{\partial y} = 3(2x)^{3y+4z} \ln(2x)$$

$$\frac{\partial w}{\partial z} = 4(2x)^{3y+4z} \ln(2x)$$

Applications and Extensions

55. Let t represent time, in seconds. We solve the equation $PV = 20T$ for V : $V = \frac{20T}{P} = 20TP^{-1}$. Now we will find a formula for $\frac{\partial V}{\partial t}$, using the Chain Rule I:

$$\begin{aligned} \frac{\partial V}{\partial T} &= 20P^{-1} = \frac{20}{P} \\ \frac{\partial V}{\partial P} &= -20TP^{-2} = \frac{-20T}{P^2} \\ \frac{dV}{dt} &= \frac{\partial V}{\partial T} \frac{dT}{dt} + \frac{\partial V}{\partial P} \frac{dP}{dt} = \frac{20}{P} \frac{dT}{dt} - \frac{20T}{P^2} \frac{dP}{dt} \end{aligned}$$

To use the Ideal Gas Law, T must be in kelvins. So, $T = 80 + 273 = 353$. We are looking for the rate of change of V with respect to time (that is, $\frac{dV}{dt}$) when

$$T = 353, \frac{dT}{dt} = 5, P = 10, \frac{dP}{dt} = -2.$$

Using the above formula for $\frac{dV}{dt}$, we get

$$\frac{dV}{dt} = \frac{20}{10} \cdot 5 - \frac{20 \cdot 353}{10^2} \cdot (-2) = 10 + 141.2 = 151.2.$$

Therefore, the rate of change of the volume is $\boxed{151.2 \text{ m}^3/\text{s}}$.

56. (a) Let t represent time, in hours. We note that the surface of the block of ice consists of six rectangles. Two of the rectangles are l by w , two are l by h , and two are w by h . So, the total surface area of the block of ice is $S = 2lw + 2lh + 2wh$. Now we will find a formula for $\frac{\partial S}{\partial t}$, using the Chain Rule I:

$$\begin{aligned}\frac{\partial S}{\partial l} &= 2w + 2h \\ \frac{\partial S}{\partial w} &= 2l + 2h \\ \frac{\partial S}{\partial h} &= 2l + 2w \\ \frac{dS}{dt} &= \frac{\partial S}{\partial l} \frac{dl}{dt} + \frac{\partial S}{\partial w} \frac{dw}{dt} + \frac{\partial S}{\partial h} \frac{dh}{dt} = (2w + 2h) \frac{dl}{dt} + (2l + 2h) \frac{dw}{dt} + (2l + 2w) \frac{dh}{dt}\end{aligned}$$

We are looking for the rate of change of S with respect to time (that is, $\frac{dS}{dt}$) when

$$l = 3, w = 2, h = 1, \frac{dl}{dt} = -1, \frac{dw}{dt} = -1, \frac{dh}{dt} = -0.5.$$

Using the above formula for $\frac{dS}{dt}$, we get

$$\frac{dS}{dt} = (2 \cdot 2 + 2 \cdot 1) \cdot (-1) + (2 \cdot 3 + 2 \cdot 1) \cdot (-1) + (2 \cdot 3 + 2 \cdot 2) \cdot (-0.5) = -19.$$

Therefore, the rate of change of the surface area is $\boxed{-19 \text{ m}^2/\text{h}}$.

- (b) Again, let t represent time, in hours. The volume of the block of ice is given by the formula $V = lwh$. Now we will find a formula for $\frac{\partial V}{\partial t}$, using the Chain Rule I:

$$\begin{aligned}\frac{\partial V}{\partial l} &= wh \\ \frac{\partial V}{\partial w} &= lh \\ \frac{\partial V}{\partial h} &= lw \\ \frac{dV}{dt} &= \frac{\partial V}{\partial l} \frac{dl}{dt} + \frac{\partial V}{\partial w} \frac{dw}{dt} + \frac{\partial V}{\partial h} \frac{dh}{dt} = wh \frac{dl}{dt} + lh \frac{dw}{dt} + lw \frac{dh}{dt}\end{aligned}$$

We are looking for the rate of change of V with respect to time (that is, $\frac{dV}{dt}$) when

$$l = 3, w = 2, h = 1, \frac{dl}{dt} = -1, \frac{dw}{dt} = -1, \frac{dh}{dt} = -0.5.$$

Using the above formula for $\frac{dV}{dt}$, we get

$$\frac{dV}{dt} = 2 \cdot 1 \cdot (-1) + 3 \cdot 1 \cdot (-1) + 3 \cdot 2 \cdot (-0.5) = -8.$$

Therefore, the rate of change of the volume is $\boxed{-8 \text{ m}^3/\text{h}}$.

57. (a) We compute the second partial derivatives of f with respect to x and t :

$$\begin{aligned}\frac{\partial f}{\partial x} &= \frac{\partial}{\partial x} (\sin(x+vt)) = \cos(x+vt) \frac{\partial}{\partial x} (x+vt) = \cos(x+vt) \\ \frac{\partial^2 f}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial x} (\cos(x+vt)) = -\sin(x+vt) \frac{\partial}{\partial x} (x+vt) = -\sin(x+vt) \\ \frac{\partial f}{\partial t} &= \frac{\partial}{\partial t} (\sin(x+vt)) = \cos(x+vt) \frac{\partial}{\partial t} (x+vt) = v \cos(x+vt) \\ \frac{\partial^2 f}{\partial t^2} &= \frac{\partial}{\partial t} \left(\frac{\partial f}{\partial t} \right) = \frac{\partial}{\partial t} (v \cos(x+vt)) = -v \sin(x+vt) \frac{\partial}{\partial t} (x+vt) = -v^2 \sin(x+vt)\end{aligned}$$

Therefore,

$$\frac{1}{v^2} \frac{\partial^2 f}{\partial t^2} = \frac{1}{v^2} (-v^2 \sin(x+vt)) = -\sin(x+vt) = \frac{\partial^2 f}{\partial x^2}.$$

So f satisfies the equation

$$\frac{\partial^2 f}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 f}{\partial t^2}.$$

(b) We compute the second partial derivatives of f with respect to x and t :

$$\begin{aligned}\frac{\partial f}{\partial x} &= \frac{\partial}{\partial x} (e^{x-vt}) = e^{x-vt} \frac{\partial}{\partial x} (x-vt) = e^{x-vt} \\ \frac{\partial^2 f}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial x} (e^{x-vt}) = e^{x-vt} \frac{\partial}{\partial x} (x-vt) = e^{x-vt} \\ \frac{\partial f}{\partial t} &= \frac{\partial}{\partial t} (e^{x-vt}) = e^{x-vt} \frac{\partial}{\partial t} (x-vt) = -ve^{x-vt} \\ \frac{\partial^2 f}{\partial t^2} &= \frac{\partial}{\partial t} \left(\frac{\partial f}{\partial t} \right) = \frac{\partial}{\partial t} (-ve^{x-vt}) = -ve^{x-vt} \frac{\partial}{\partial t} (x-vt) = v^2 e^{x-vt}\end{aligned}$$

Therefore,

$$\frac{1}{v^2} \frac{\partial^2 f}{\partial t^2} = \frac{1}{v^2} (v^2 e^{x-vt}) = e^{x-vt} = \frac{\partial^2 f}{\partial x^2}.$$

So f satisfies the equation

$$\frac{\partial^2 f}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 f}{\partial t^2}.$$

(c) We compute the second partial derivatives of f with respect to x and t :

$$\begin{aligned}\frac{\partial f}{\partial x} &= \frac{\partial}{\partial x} (\sin x + \sin(vt)) = \cos x \\ \frac{\partial^2 f}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = \frac{\partial}{\partial x} (\cos x) = -\sin x \\ \frac{\partial f}{\partial t} &= \frac{\partial}{\partial t} (\sin x + \sin(vt)) = \cos(vt) \frac{\partial}{\partial t} (vt) = v \cos(vt) \\ \frac{\partial^2 f}{\partial t^2} &= \frac{\partial}{\partial t} \left(\frac{\partial f}{\partial t} \right) = \frac{\partial}{\partial t} (v \cos(vt)) = -v \sin(vt) \frac{\partial}{\partial t} (vt) = -v^2 \sin(vt)\end{aligned}$$

Therefore,

$$\frac{1}{v^2} \frac{\partial^2 f}{\partial t^2} = \frac{1}{v^2} (-v^2 \sin(vt)) = -\sin(vt) \neq -\sin x = \frac{\partial^2 f}{\partial x^2}.$$

To verify that $-\sin(vt)$ and $-\sin x$ are not equal, we can, for example, substitute $t = 0$ and $x = \frac{\pi}{2}$; in that case, $-\sin(vt) = 0$ and $-\sin x = -1$. So they are indeed not equal. So f does not satisfy the equation

$$\frac{\partial^2 f}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 f}{\partial t^2}.$$

- (d) Let $u = x + vt$. Then $f(u) = f(x + vt)$. We compute the second partial derivatives of f with respect to x and t , using Chain Rule II.

$$\begin{aligned}\frac{\partial f}{\partial x} &= \frac{df}{du} \frac{\partial u}{\partial x} = \frac{df}{du} \cdot 1 = \frac{df}{du} \\ \frac{\partial^2 f}{\partial x^2} &= \frac{\partial}{\partial x} \left(\frac{df}{du} \right) = \frac{d}{du} \left(\frac{df}{du} \right) \cdot \frac{\partial u}{\partial x} = \frac{d}{du} \left(\frac{df}{du} \right) \cdot 1 = \frac{d^2 f}{du^2} \\ \frac{\partial f}{\partial t} &= \frac{df}{du} \frac{\partial u}{\partial t} = \frac{df}{du} \cdot v = v \frac{df}{du} \\ \frac{\partial^2 f}{\partial t^2} &= \frac{\partial}{\partial t} \left(v \frac{df}{du} \right) = v \frac{d}{du} \left(\frac{df}{du} \right) \cdot \frac{\partial u}{\partial t} = v \frac{d}{du} \left(\frac{df}{du} \right) \cdot v = v^2 \frac{d^2 f}{du^2}\end{aligned}$$

Therefore,

$$\frac{1}{v^2} \frac{\partial^2 f}{\partial t^2} = \frac{1}{v^2} \left(v^2 \frac{d^2 f}{du^2} \right) = \frac{d^2 f}{du^2} = \frac{\partial^2 f}{\partial x^2}.$$

So $f(x + vt)$ satisfies the equation

$$\frac{\partial^2 f}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 f}{\partial t^2}.$$

58. (a) Let t represent time, in years. We will find a formula for $\frac{\partial Q}{\partial t}$, using the Chain Rule I:

$$\begin{aligned}\frac{\partial Q}{\partial L} &= 400M^{0.7} \cdot (0.3)L^{-0.7} = 120M^{0.7}L^{-0.7} \\ \frac{\partial Q}{\partial M} &= 400L^{0.3} \cdot (0.7)M^{-0.3} = 280M^{-0.3}L^{0.3} \\ \frac{dQ}{dt} &= \frac{\partial Q}{\partial L} \frac{dL}{dt} + \frac{\partial Q}{\partial M} \frac{dM}{dt} = 120M^{0.7}L^{-0.7} \frac{dL}{dt} + 280M^{-0.3}L^{0.3} \frac{dM}{dt}\end{aligned}$$

Now, first, we are looking for the rate of change of Q with respect to time (that is, $\frac{dQ}{dt}$) when

$$L = 19, M = 21, \frac{dL}{dt} = -4, \frac{dM}{dt} = 2.$$

Using the above formula for $\frac{dQ}{dt}$, we get

$$\frac{dQ}{dt} = 120 \cdot 21^{0.7} \cdot 19^{-0.7} \cdot (-4) + 280 \cdot 21^{-0.3} \cdot 19^{0.3} \cdot 2 \approx 28.601889.$$

Therefore, since Q represents output in thousands of units, the rate of change of the production is $\boxed{\approx 28601.889 \text{ units/yr}}$.

- (b) Second, we are looking for the rate of change of Q with respect to time (that is, $\frac{dQ}{dt}$) when

$$L = 21, M = 20, \frac{dL}{dt} = -4, \frac{dM}{dt} = 2.$$

Using the above formula for $\frac{dQ}{dt}$, we get

$$\frac{dQ}{dt} = 120 \cdot 20^{0.7} \cdot 21^{-0.7} \cdot (-4) + 280 \cdot 20^{-0.3} \cdot 21^{0.3} \cdot 2 \approx 104.373740.$$

Therefore, since Q represents output in thousands of units, the rate of change of the production is $\boxed{\approx 104373.740 \text{ units/yr}}$.

59. (a) Using Chain Rule II, we have:

$$\frac{\partial y}{\partial s} = \frac{\partial y}{\partial a} \frac{\partial a}{\partial s} + \frac{\partial y}{\partial b} \frac{\partial b}{\partial s} = f_a(a, b)h_s(s, t) + f_b(a, b)k_s(s, t) = f_a(a, b)\frac{\partial h}{\partial s}(s, t) + f_b(a, b)\frac{\partial k}{\partial s}(s, t).$$

When $s = 1$ and $t = 3$, we have $a = h(1, 3) = 6$ and $b = k(1, 3) = 2$, so

$$\frac{\partial y}{\partial s}(1, 3) = f_a(6, 2)\frac{\partial h}{\partial s}(1, 3) + f_b(6, 2)\frac{\partial k}{\partial s}(1, 3) = 7 \cdot 4 + 2 \cdot (-3) = 22.$$

$$\text{So } \boxed{\frac{\partial y}{\partial s}(1, 3) = 22}.$$

- (b) Using Chain Rule II, we have:

$$\frac{\partial y}{\partial t} = \frac{\partial y}{\partial a} \frac{\partial a}{\partial t} + \frac{\partial y}{\partial b} \frac{\partial b}{\partial t} = f_a(a, b)h_t(s, t) + f_b(a, b)k_t(s, t) = f_a(a, b)\frac{\partial h}{\partial t}(s, t) + f_b(a, b)\frac{\partial k}{\partial t}(s, t).$$

When $s = 1$ and $t = 3$, we have $a = h(1, 3) = 6$ and $b = k(1, 3) = 2$, so

$$\frac{\partial y}{\partial t}(1, 3) = f_a(6, 2)\frac{\partial h}{\partial t}(1, 3) + f_b(6, 2)\frac{\partial k}{\partial t}(1, 3) = 7 \cdot 1 + 2 \cdot (-5) = -3.$$

$$\text{So } \boxed{\frac{\partial y}{\partial t}(1, 3) = -3}.$$

60. (a) Using Chain Rule II, we have:

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial s} = f_x(x, y)g_s(s, t) + f_y(x, y)h_s(s, t) = f_x(x, y)\frac{\partial x}{\partial s}(s, t) + f_y(x, y)\frac{\partial y}{\partial s}(s, t).$$

When $s = 2$ and $t = -1$, we have $x = g(2, -1) = 3$ and $y = h(2, -1) = 4$, so

$$\frac{\partial z}{\partial s}(2, -1) = f_x(3, 4)\frac{\partial x}{\partial s}(2, -1) + f_y(3, 4)\frac{\partial y}{\partial s}(2, -1) = 12 \cdot 5 + 7 \cdot 2 = 74.$$

$$\text{So } \boxed{\frac{\partial z}{\partial s}(2, -1) = 74}.$$

- (b) Using Chain Rule II, we have:

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x} \frac{\partial x}{\partial t} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial t} = f_x(x, y)g_t(s, t) + f_y(x, y)h_t(s, t) = f_x(x, y)\frac{\partial x}{\partial t}(s, t) + f_y(x, y)\frac{\partial y}{\partial t}(s, t).$$

When $s = 2$ and $t = -1$, we have $x = g(2, -1) = 3$ and $y = h(2, -1) = 4$, so

$$\frac{\partial z}{\partial t}(2, -1) = f_x(3, 4)\frac{\partial x}{\partial t}(2, -1) + f_y(3, 4)\frac{\partial y}{\partial t}(2, -1) = 12 \cdot (-3) + 7 \cdot (-2) = -50.$$

$$\text{So } \boxed{\frac{\partial z}{\partial t}(2, -1) = -50}.$$

61. We will use Chain Rule II many times to solve this problem:

[illegible]

Therefore, we have the following formulas:

$$\frac{\partial^2 z}{\partial u^2} = \frac{\partial z}{\partial x} \frac{\partial^2 x}{\partial u^2} + \frac{\partial z}{\partial y} \frac{\partial^2 y}{\partial u^2} + \frac{\partial^2 z}{\partial x^2} \left(\frac{\partial x}{\partial u} \right)^2 + 2 \frac{\partial^2 z}{\partial x \partial y} \frac{\partial x}{\partial u} \frac{\partial y}{\partial u} + \frac{\partial^2 z}{\partial y^2} \left(\frac{\partial y}{\partial u} \right)^2$$

$$\boxed{\frac{\partial^2 z}{\partial v^2} = \frac{\partial z}{\partial x} \frac{\partial^2 x}{\partial v^2} + \frac{\partial z}{\partial y} \frac{\partial^2 y}{\partial v^2} + \frac{\partial^2 z}{\partial x^2} \left(\frac{\partial x}{\partial v} \right)^2 + 2 \frac{\partial^2 z}{\partial x \partial y} \frac{\partial x}{\partial v} \frac{\partial y}{\partial v} + \frac{\partial^2 z}{\partial y^2} \left(\frac{\partial y}{\partial v} \right)^2}$$

62. We will use Chain Rule II to compute the partial derivatives of z with respect to r and θ .

$$\begin{aligned} \frac{\partial z}{\partial r} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial r} = \cos \theta \frac{\partial z}{\partial x} + \sin \theta \frac{\partial z}{\partial y} \\ \frac{\partial z}{\partial \theta} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial \theta} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial \theta} = -r \sin \theta \frac{\partial z}{\partial x} + r \cos \theta \frac{\partial z}{\partial y} \end{aligned}$$

Therefore,

$$\begin{aligned} \left(\frac{\partial z}{\partial r} \right)^2 + \frac{1}{r^2} \left(\frac{\partial z}{\partial \theta} \right)^2 &= \left(\cos \theta \frac{\partial z}{\partial x} + \sin \theta \frac{\partial z}{\partial y} \right)^2 + \frac{1}{r^2} \left(-r \sin \theta \frac{\partial z}{\partial x} + r \cos \theta \frac{\partial z}{\partial y} \right)^2 \\ &= \left(\cos \theta \frac{\partial z}{\partial x} + \sin \theta \frac{\partial z}{\partial y} \right)^2 + \left(-\sin \theta \frac{\partial z}{\partial x} + \cos \theta \frac{\partial z}{\partial y} \right)^2 \\ &= \cos^2 \theta \left(\frac{\partial z}{\partial x} \right)^2 + 2 \sin \theta \cos \theta \frac{\partial z}{\partial x} \frac{\partial z}{\partial y} + \sin^2 \theta \left(\frac{\partial z}{\partial y} \right)^2 + \sin^2 \theta \left(\frac{\partial z}{\partial x} \right)^2 - 2 \sin \theta \cos \theta \frac{\partial z}{\partial x} \frac{\partial z}{\partial y} + \cos^2 \theta \left(\frac{\partial z}{\partial y} \right)^2 \\ &= (\cos^2 \theta + \sin^2 \theta) \left(\frac{\partial z}{\partial x} \right)^2 + (\cos^2 \theta + \sin^2 \theta) \left(\frac{\partial z}{\partial y} \right)^2 = \left(\frac{\partial z}{\partial x} \right)^2 + \left(\frac{\partial z}{\partial y} \right)^2 \end{aligned}$$

We conclude that

$$\left(\frac{\partial z}{\partial r} \right)^2 + \frac{1}{r^2} \left(\frac{\partial z}{\partial \theta} \right)^2 = \left(\frac{\partial z}{\partial x} \right)^2 + \left(\frac{\partial z}{\partial y} \right)^2.$$

63. We will use Chain Rule II to compute the partial derivatives of z with respect to u and v .

$$\begin{aligned} \frac{\partial f}{\partial u} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial u} = \cos \theta \frac{\partial f}{\partial x} + \sin \theta \frac{\partial f}{\partial y} \\ \frac{\partial f}{\partial v} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial v} = -\sin \theta \frac{\partial f}{\partial x} + \cos \theta \frac{\partial f}{\partial y} \end{aligned}$$

Therefore,

$$\begin{aligned} \left(\frac{\partial f}{\partial u} \right)^2 + \left(\frac{\partial f}{\partial v} \right)^2 &= \left(\cos \theta \frac{\partial f}{\partial x} + \sin \theta \frac{\partial f}{\partial y} \right)^2 + \left(-\sin \theta \frac{\partial f}{\partial x} + \cos \theta \frac{\partial f}{\partial y} \right)^2 \\ &= \cos^2 \theta \left(\frac{\partial f}{\partial x} \right)^2 + 2 \sin \theta \cos \theta \frac{\partial f}{\partial x} \frac{\partial f}{\partial y} + \sin^2 \theta \left(\frac{\partial f}{\partial y} \right)^2 + \sin^2 \theta \left(\frac{\partial f}{\partial x} \right)^2 - 2 \sin \theta \cos \theta \frac{\partial f}{\partial x} \frac{\partial f}{\partial y} + \cos^2 \theta \left(\frac{\partial f}{\partial y} \right)^2 \\ &= (\cos^2 \theta + \sin^2 \theta) \left(\frac{\partial f}{\partial x} \right)^2 + (\cos^2 \theta + \sin^2 \theta) \left(\frac{\partial f}{\partial y} \right)^2 = \left(\frac{\partial f}{\partial x} \right)^2 + \left(\frac{\partial f}{\partial y} \right)^2 \end{aligned}$$

We conclude that

$$\left(\frac{\partial f}{\partial u} \right)^2 + \left(\frac{\partial f}{\partial v} \right)^2 = \left(\frac{\partial f}{\partial x} \right)^2 + \left(\frac{\partial f}{\partial y} \right)^2.$$

64. If we let $x = u - v$ and $y = v - u$, then we have $z = f(x, y)$, and we can use Chain Rule II to compute the partial derivatives of z with respect to u and v :

$$\begin{aligned} \frac{\partial z}{\partial u} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial u} = \frac{\partial z}{\partial x} \cdot 1 + \frac{\partial z}{\partial y} \cdot (-1) = \frac{\partial z}{\partial x} - \frac{\partial z}{\partial y} \\ \frac{\partial z}{\partial v} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial v} = \frac{\partial z}{\partial x} \cdot (-1) + \frac{\partial z}{\partial y} \cdot 1 = -\frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} \end{aligned}$$

Therefore,

$$\frac{\partial z}{\partial u} + \frac{\partial z}{\partial v} = \frac{\partial z}{\partial x} - \frac{\partial z}{\partial y} - \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} = 0.$$

We conclude that

$$\frac{\partial z}{\partial u} + \frac{\partial z}{\partial v} = 0.$$

65. If we let $x = u^2 - v^2$ and $y = v$, then we can write $z = yf(x)$, so $\frac{\partial z}{\partial y} = f(x)$. This implies that $y \frac{\partial z}{\partial y} = yf(x) = z$, so $\frac{\partial z}{\partial y} = \frac{z}{y} = \frac{z}{v}$. Then, we can use Chain Rule II to compute the partial derivatives of z with respect to u and v :

$$\begin{aligned} \frac{\partial z}{\partial u} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial u} = \frac{\partial z}{\partial x} \cdot 2u + \frac{\partial z}{\partial y} \cdot 0 = 2u \frac{\partial z}{\partial x} \\ \frac{\partial z}{\partial v} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial v} = \frac{\partial z}{\partial x} \cdot (-2v) + \frac{\partial z}{\partial y} \cdot 1 = -2v \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} \end{aligned}$$

Therefore,

$$v \frac{\partial z}{\partial u} + u \frac{\partial z}{\partial v} = 2uv \frac{\partial z}{\partial x} - 2uv \frac{\partial z}{\partial x} + u \frac{\partial z}{\partial y} = u \frac{\partial z}{\partial y} = \frac{uz}{v}.$$

We conclude that

$$v \frac{\partial z}{\partial u} + u \frac{\partial z}{\partial v} = \frac{uz}{v}.$$

66. We use an extension of Chain Rule II to compute the partial derivatives of w with respect to x , y and z .

$$\begin{aligned} \frac{\partial w}{\partial x} &= \frac{dw}{du} \frac{\partial u}{\partial x} = \frac{dw}{du} \frac{\partial}{\partial x} \left((x^2 + y^2 + z^2)^{1/2} \right) \\ &= \frac{dw}{du} \cdot \frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-1/2} \frac{\partial}{\partial x} (x^2 + y^2 + z^2) = \frac{x}{\sqrt{x^2 + y^2 + z^2}} \frac{dw}{du} \\ \frac{\partial w}{\partial y} &= \frac{dw}{du} \frac{\partial u}{\partial y} = \frac{dw}{du} \frac{\partial}{\partial y} \left((x^2 + y^2 + z^2)^{1/2} \right) \\ &= \frac{dw}{du} \cdot \frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-1/2} \frac{\partial}{\partial y} (x^2 + y^2 + z^2) = \frac{y}{\sqrt{x^2 + y^2 + z^2}} \frac{dw}{du} \\ \frac{\partial w}{\partial z} &= \frac{dw}{du} \frac{\partial u}{\partial z} = \frac{dw}{du} \frac{\partial}{\partial z} \left((x^2 + y^2 + z^2)^{1/2} \right) \\ &= \frac{dw}{du} \cdot \frac{1}{2} \cdot (x^2 + y^2 + z^2)^{-1/2} \frac{\partial}{\partial z} (x^2 + y^2 + z^2) = \frac{z}{\sqrt{x^2 + y^2 + z^2}} \frac{dw}{du} \end{aligned}$$

Therefore,

$$\begin{aligned} \left(\frac{\partial w}{\partial x} \right)^2 + \left(\frac{\partial w}{\partial y} \right)^2 + \left(\frac{\partial w}{\partial z} \right)^2 &= \left(\frac{x^2}{x^2 + y^2 + z^2} + \frac{y^2}{x^2 + y^2 + z^2} + \frac{z^2}{x^2 + y^2 + z^2} \right) \left(\frac{dw}{du} \right)^2 \\ &= \frac{x^2 + y^2 + z^2}{x^2 + y^2 + z^2} \left(\frac{dw}{du} \right)^2 = \left(\frac{dw}{du} \right)^2 \end{aligned}$$

We conclude that

$$\left(\frac{\partial w}{\partial x} \right)^2 + \left(\frac{\partial w}{\partial y} \right)^2 + \left(\frac{\partial w}{\partial z} \right)^2 = \left(\frac{dw}{du} \right)^2.$$

67. Let $u = \frac{x}{y}$. Then $z = f(u)$. We use Chain Rule II to compute the partial derivatives of z with respect to x and y .

$$\begin{aligned}\frac{\partial z}{\partial x} &= \frac{dz}{du} \frac{\partial u}{\partial x} = \frac{dz}{du} \frac{\partial}{\partial x} \left(\frac{x}{y} \right) = \frac{1}{y} \frac{dz}{du} \\ \frac{\partial z}{\partial y} &= \frac{dz}{du} \frac{\partial u}{\partial y} = \frac{dz}{du} \frac{\partial}{\partial y} (xy^{-1}) = \frac{dz}{du} (-xy^{-2}) = \frac{-x}{y^2} \frac{dz}{du}\end{aligned}$$

Therefore,

$$x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} = \frac{x}{y} \frac{dz}{du} - \frac{x}{y} \frac{dz}{du} = 0.$$

We conclude that

$$x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} = 0.$$

68. Let $x = \frac{u}{v}$ and $y = \frac{v}{w}$. Then $z = f(x, y)$. We use an extension of Chain Rule II to compute the partial derivatives of z with respect to u , v and w .

$$\begin{aligned}\frac{\partial z}{\partial u} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial u} = \frac{\partial z}{\partial x} \frac{\partial}{\partial u} \left(\frac{u}{v} \right) + \frac{\partial z}{\partial y} \cdot 0 = \frac{1}{v} \frac{\partial z}{\partial x} \\ \frac{\partial z}{\partial v} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial v} = \frac{\partial z}{\partial x} \frac{\partial}{\partial v} \left(\frac{u}{v} \right) + \frac{\partial z}{\partial y} \cdot \frac{\partial}{\partial v} \left(\frac{v}{w} \right) = \frac{\partial z}{\partial x} (-uv^{-2}) + \frac{\partial z}{\partial y} \frac{1}{w} = -\frac{u}{v^2} \frac{\partial z}{\partial x} + \frac{1}{w} \frac{\partial z}{\partial y} \\ \frac{\partial z}{\partial w} &= \frac{\partial z}{\partial x} \frac{\partial x}{\partial w} + \frac{\partial z}{\partial y} \frac{\partial y}{\partial w} = \frac{\partial z}{\partial x} \cdot 0 + \frac{\partial z}{\partial y} \cdot \frac{\partial}{\partial w} \left(\frac{v}{w} \right) = \frac{\partial z}{\partial y} (-vw^{-2}) = -\frac{v}{w^2} \frac{\partial z}{\partial y}\end{aligned}$$

Therefore,

$$u \frac{\partial z}{\partial u} + v \frac{\partial z}{\partial v} + w \frac{\partial z}{\partial w} = \frac{u}{v} \frac{\partial z}{\partial x} - \frac{u}{v} \frac{\partial z}{\partial x} + \frac{v}{w} \frac{\partial z}{\partial y} - \frac{v}{w} \frac{\partial z}{\partial y} = 0.$$

We conclude that

$$u \frac{\partial z}{\partial u} + v \frac{\partial z}{\partial v} + w \frac{\partial z}{\partial w} = 0.$$

69. We will use Chain Rule II to solve this problem:

$$\begin{aligned}\frac{\partial f}{\partial r} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial r} = \cos \theta \frac{\partial f}{\partial x} + \sin \theta \frac{\partial f}{\partial y} \\ \frac{\partial^2 f}{\partial r^2} &= \frac{\partial}{\partial r} \left(\cos \theta \frac{\partial f}{\partial x} + \sin \theta \frac{\partial f}{\partial y} \right) = \cos \theta \frac{\partial}{\partial r} \left(\frac{\partial f}{\partial x} \right) + \sin \theta \frac{\partial}{\partial r} \left(\frac{\partial f}{\partial y} \right) \\ &= \cos \theta \left(\frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) \frac{\partial x}{\partial r} + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) \frac{\partial y}{\partial r} \right) + \sin \theta \left(\frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) \frac{\partial x}{\partial r} + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) \frac{\partial y}{\partial r} \right) \\ &= \cos \theta \frac{\partial^2 f}{\partial x^2} \frac{\partial x}{\partial r} + \cos \theta \frac{\partial^2 f}{\partial y \partial x} \frac{\partial y}{\partial r} + \sin \theta \frac{\partial^2 f}{\partial x \partial y} \frac{\partial x}{\partial r} + \sin \theta \frac{\partial^2 f}{\partial y^2} \frac{\partial y}{\partial r} \\ &= \cos^2 \theta \frac{\partial^2 f}{\partial x^2} + \sin \theta \cos \theta \frac{\partial^2 f}{\partial y \partial x} + \sin \theta \cos \theta \frac{\partial^2 f}{\partial x \partial y} + \sin^2 \theta \frac{\partial^2 f}{\partial y^2} \\ \frac{\partial f}{\partial \theta} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial \theta} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial \theta} = -r \sin \theta \frac{\partial f}{\partial x} + r \cos \theta \frac{\partial f}{\partial y} \\ \frac{\partial^2 f}{\partial \theta^2} &= \frac{\partial}{\partial \theta} \left(-r \sin \theta \frac{\partial f}{\partial x} + r \cos \theta \frac{\partial f}{\partial y} \right)\end{aligned}$$

$$\begin{aligned}
&= -r \cos \theta \frac{\partial f}{\partial x} - r \sin \theta \frac{\partial}{\partial \theta} \left(\frac{\partial f}{\partial x} \right) - r \sin \theta \frac{\partial f}{\partial y} + r \cos \theta \frac{\partial}{\partial \theta} \left(\frac{\partial f}{\partial y} \right) \\
&= -r \cos \theta \frac{\partial f}{\partial x} - r \sin \theta \left(\frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) \frac{\partial x}{\partial \theta} + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) \frac{\partial y}{\partial \theta} \right) - r \sin \theta \frac{\partial f}{\partial y} + r \cos \theta \left(\frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) \frac{\partial x}{\partial \theta} + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) \frac{\partial y}{\partial \theta} \right) \\
&= -r \cos \theta \frac{\partial f}{\partial x} + r^2 \sin^2 \theta \frac{\partial^2 f}{\partial x^2} - r^2 \sin \theta \cos \theta \frac{\partial^2 f}{\partial y \partial x} - r \sin \theta \frac{\partial f}{\partial y} - r^2 \sin \theta \cos \theta \frac{\partial^2 f}{\partial x \partial y} + r^2 \cos^2 \theta \frac{\partial^2 f}{\partial y^2}
\end{aligned}$$

Therefore,

$$\begin{aligned}
\frac{\partial^2 f}{\partial r^2} + \frac{1}{r} \left(\frac{\partial f}{\partial r} \right) + \frac{1}{r^2} \left(\frac{\partial^2 f}{\partial \theta^2} \right) &= \cos^2 \theta \frac{\partial^2 f}{\partial x^2} + \sin \theta \cos \theta \frac{\partial^2 f}{\partial y \partial x} + \sin \theta \cos \theta \frac{\partial^2 f}{\partial x \partial y} \\
&\quad + \sin^2 \theta \frac{\partial^2 f}{\partial y^2} + \frac{1}{r} \cos \theta \frac{\partial f}{\partial x} + \frac{1}{r} \sin \theta \frac{\partial f}{\partial y} \\
&\quad - \frac{1}{r} \cos \theta \frac{\partial f}{\partial x} + \sin^2 \theta \frac{\partial^2 f}{\partial x^2} - \sin \theta \cos \theta \frac{\partial^2 f}{\partial y \partial x} \\
&\quad - \frac{1}{r} \sin \theta \frac{\partial f}{\partial y} - \sin \theta \cos \theta \frac{\partial^2 f}{\partial x \partial y} + \cos \theta \frac{\partial^2 f}{\partial y^2} \\
&= (\cos^2 \theta + \sin^2 \theta) \frac{\partial^2 f}{\partial x^2} + (\sin^2 \theta + \cos^2 \theta) \frac{\partial^2 f}{\partial y^2} \\
&= \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = \Delta f.
\end{aligned}$$

We conclude that

$$\Delta f = \frac{\partial^2 f}{\partial r^2} + \frac{1}{r} \left(\frac{\partial f}{\partial r} \right) + \frac{1}{r^2} \left(\frac{\partial^2 f}{\partial \theta^2} \right).$$

70. Using the Implicit Differentiation Formulas II, we have $\frac{\partial z}{\partial x} = -\frac{F_x}{F_z}$, $\frac{\partial x}{\partial y} = -\frac{F_y}{F_x}$ and $\frac{\partial y}{\partial z} = -\frac{F_z}{F_y}$. We conclude that

$$\frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial y} \cdot \frac{\partial y}{\partial z} = \left(-\frac{F_x}{F_z} \right) \left(-\frac{F_y}{F_x} \right) \left(-\frac{F_z}{F_y} \right) = -\frac{F_x F_y F_z}{F_z F_x F_y} = -1.$$

Challenge Problems

71. (a) We know, from the Implicit Differentiation Formula I, that

$$\frac{dy}{dx} = -\frac{F_x}{F_y}, \quad \text{if } F_y \neq 0.$$

We let $u = x$ and $v = y$ (which is a function of x). Then F_x and F_y become functions of u and v , which are both functions of x . So we can use Chain Rule I to compute the derivatives of F_x and F_y with respect to x .

$$\begin{aligned}
\frac{dF_x}{dx} &= \frac{\partial F_x}{\partial u} \frac{du}{dx} + \frac{\partial F_x}{\partial v} \frac{dv}{dx} = \frac{\partial F_x}{\partial x} \cdot 1 + \frac{\partial F_x}{\partial y} \frac{dy}{dx} = F_{xx} + F_{xy} \frac{dy}{dx} \\
\frac{dF_y}{dx} &= \frac{\partial F_y}{\partial u} \frac{du}{dx} + \frac{\partial F_y}{\partial v} \frac{dv}{dx} = \frac{\partial F_y}{\partial x} \cdot 1 + \frac{\partial F_y}{\partial y} \frac{dy}{dx} = F_{yx} + F_{yy} \frac{dy}{dx}
\end{aligned}$$

Now, using the Quotient Rule, we find that

$$\begin{aligned}
\frac{d^2y}{dx^2} &= \frac{d}{dx} \left(\frac{dy}{dx} \right) = \frac{d}{dx} \left(-\frac{F_x}{F_y} \right) = -\frac{\frac{d}{dx}(F_x) \cdot F_y - F_x \cdot \frac{d}{dx}(F_y)}{F_y^2} \\
&= -\frac{(F_{xx} + F_{xy} \frac{dy}{dx})F_y - F_x(F_{yx} + F_{yy} \frac{dy}{dx})}{F_y^2} \\
&= -\frac{\left(F_{xx} + F_{xy} \left(\frac{-F_x}{F_y}\right)\right)F_y - F_x\left(F_{yx} + F_{yy} \left(\frac{-F_x}{F_y}\right)\right)}{F_y^2} \\
&= -\frac{F_{xx}F_y^2 - F_{xy}F_xF_y - F_xF_{yx}F_y + F_{yy}F_x^2}{F_y^3} \\
&= -\frac{F_y^2F_{xx} - 2F_xF_yF_{xy} + F_x^2F_{yy}}{F_y^3}
\end{aligned}$$

The last equality is correct because F has continuous second-order partial derivatives, so that Clairaut's Theorem applies. Therefore,

$$\frac{d^2y}{dx^2} = -\frac{F_y^2F_{xx} - 2F_xF_yF_{xy} + F_x^2F_{yy}}{F_y^3}, \text{ if } F_y \neq 0.$$

(b) We take $F(x, y) = x^3 + 3xy - y^3 - 6$. Then,

$$\begin{aligned}
F_x &= 3x^2 + 3y \\
F_y &= 3x - 3y^2 \\
F_{xx} &= 6x \\
F_{xy} &= 3 \\
F_{yy} &= -6y
\end{aligned}$$

So, using the formula from part (a), we get

$$\begin{aligned}
\frac{d^2y}{dx^2} &= -\frac{F_y^2F_{xx} - 2F_xF_yF_{xy} + F_x^2F_{yy}}{F_y^3} \\
&= -\frac{6x(3x - 3y^2)^2 - 6(3x^2 + 3y)(3x - 3y^2) - 6y(3x^2 + 3y)^2}{(3x - 3y^2)^3} \\
&= \frac{-6x(3x - 3y^2)^2 + 6(3x^2 + 3y)(3x - 3y^2) + 6y(3x^2 + 3y)^2}{(3x - 3y^2)^3}
\end{aligned}$$

Therefore, $\boxed{\frac{d^2y}{dx^2} = \frac{-6x(3x - 3y^2)^2 + 6(3x^2 + 3y)(3x - 3y^2) + 6y(3x^2 + 3y)^2}{(3x - 3y^2)^3}}.$

72. Using the Fundamental Theorem of Calculus, Part I, and Chain Rule II, we have:

$$\begin{aligned}
 f_x &= e^{-x^2/(4\lambda t)} \cdot \frac{\partial}{\partial x} \left(\frac{x}{2\sqrt{\lambda t}} \right) = \frac{e^{-x^2/(4\lambda t)}}{2\sqrt{\lambda t}} \\
 f_{xx} &= \frac{1}{2\sqrt{\lambda t}} \cdot \frac{\partial}{\partial x} \left(e^{-x^2/(4\lambda t)} \right) = \frac{1}{2\sqrt{\lambda t}} e^{-x^2/(4\lambda t)} \left(\frac{-2x}{4\lambda t} \right) \\
 &= \frac{-x}{4t^{3/2}\lambda^{3/2}} e^{-x^2/(4\lambda t)} \\
 f_t &= e^{-x^2/(4\lambda t)} \frac{\partial}{\partial t} \left(\frac{xt^{-1/2}}{2\sqrt{\lambda}} \right) \\
 &= e^{-x^2/(4\lambda t)} \cdot \left(\frac{-1}{2} \right) \frac{xt^{-3/2}}{2\sqrt{\lambda}} = \frac{-x}{4t^{3/2}\lambda^{1/2}} e^{-x^2/(4\lambda t)}
 \end{aligned}$$

Therefore,

$$\lambda f_{xx} = \frac{-x}{4t^{3/2}\lambda^{1/2}} e^{-x^2/(4\lambda t)} = f_t.$$

We conclude that $f_t = \lambda f_{xx}$.

Chapter 12: Functions of Several Variables

Chapter 12 Review

- $f(1, 1) = e^1 \ln 1 = e(0) = 0$. So, $\boxed{f(1, 1) = 0}$.
 - $\boxed{f(x + \Delta x, y) = e^{x+\Delta x} \ln y}$.
 - $\boxed{f(x, y + \Delta y) = e^x \ln(y + \Delta y)}$.
- $f(1, 1) = 2(1)^2 + 6(1)(1) - (1)^3 = 7$. So, $\boxed{f(1, 1) = 7}$.
 - $\boxed{f(x + \Delta x, y) = 2(x + \Delta x)^2 + 6(x + \Delta x)y - y^3}$.
 - $\boxed{f(x, y + \Delta y) = 2x^2 + 6x(y + \Delta y) - (y + \Delta y)^3}$.
- $f\left(\ln 3, \frac{1}{2}, \frac{1}{4}\right) = e^{\ln 3} \sin^{-1} \left[\frac{1}{2} + 2 \left(\frac{1}{4} \right) \right] = 3 \sin^{-1} \left(\frac{1}{2} + \frac{1}{2} \right) = 3 \sin^{-1}(1) = 3 \cdot \frac{\pi}{2} = \frac{3\pi}{2}$. So, $\boxed{f\left(\ln 3, \frac{1}{2}, \frac{1}{4}\right) = \frac{3\pi}{2}}$.
 - $f\left(1, 0, \frac{1}{4}\right) = e^1 \sin^{-1} \left[0 + 2 \left(\frac{1}{4} \right) \right] = e \sin^{-1} \left(\frac{1}{2} \right) = e \cdot \frac{\pi}{6} = \frac{e\pi}{6}$. So, $\boxed{f\left(1, 0, \frac{1}{4}\right) = \frac{e\pi}{6}}$.
 - $f(0, 0, 0) = e^0 \sin^{-1}(0 + 2(0)) = (1) \sin^{-1}(0) = (1)(0) = 0$. So, $\boxed{f(0, 0, 0) = 0}$.
- A logarithm may not take a negative number as its input; so, we require that $x^2 - 3y > 0$. Equivalently:

$$\begin{aligned}
 x^2 &> 3y \\
 \frac{x^2}{3} &> y
 \end{aligned}$$

$$y < \frac{x^2}{3}$$

So, the domain is the set of points (x, y) satisfying $y < \frac{x^2}{3}$, or the set $\boxed{\{(x, y) | y < \frac{x^2}{3}\}}$. This is the portion of the xy -plane that lies strictly below the parabola $y = \frac{x^2}{3}$. See the graph below:

5. In order for f to be defined, the quantity underneath the square root must be nonnegative. So, we require that $9 - x^2 - 4y^2 \geq 0$. Equivalently, $9 \geq x^2 + 4y^2$. So the domain is the set $\boxed{\{(x, y) | x^2 + 4y^2 \leq 9\}}$.

To find the graph, we transform the above inequality:

$$1 \geq \frac{x^2}{9} + \frac{4y^2}{9}$$

$$1 \geq \frac{x^2}{9} + \frac{y^2}{9/4}$$

$$\frac{x^2}{9} + \frac{y^2}{9/4} \leq 1$$

So, the domain is the set of points (x, y) satisfying $\frac{x^2}{9} + \frac{y^2}{9/4} \leq 1$. This is an ellipse centered at the origin with semi-major axis 3 and semi-minor axis $\frac{3}{2}$, and the region inside it. See the graph below:

6. In order for f to be defined, the quantity underneath the square root must be nonnegative. Because it is in the denominator, it must also be nonzero. So, we require that $5 - y^2 > 0$. Equivalently:

$$5 > y^2$$

$$y^2 < 5$$

$$-\sqrt{5} < y < \sqrt{5}$$

So, the domain is the set of points (x, y) satisfying $-\sqrt{5} < y < \sqrt{5}$, or the set $\{(x, y) \mid -\sqrt{5} < y < \sqrt{5}\}$.

This is the horizontal “strip” of the plane that lies strictly between the horizontal lines $y = \sqrt{5}$ and $y = -\sqrt{5}$. See the graph below:

7. Because this function is rational, with a polynomial as both its numerator and denominator, it will only be undefined where the denominator is 0, or when $x + 2y = 0$. This occurs along the line $x = -2y$, or $y = -\frac{x}{2}$. So, the domain is the set of points (x, y) satisfying $y \neq -\frac{x}{2}$, or the set $\{(x, y) \mid y \neq -\frac{x}{2}\}$. This is all of $\mathbb{R}^2$ except for the line $y = -\frac{x}{2}$. See the graph below:

8. Because this function is rational, with a polynomial as both its numerator and denominator, it will only be undefined where the denominator is 0, or when $x^2 = 0$. This occurs only at $x = 0$. So, the domain is the set of points (x, y, z) satisfying $x \neq 0$, or the set $\{(x, y, z) \mid x \neq 0\}$. This is all of $\mathbb{R}^3$ except for the plane $x = 0$.
9. A logarithm may not take a negative number as its input; so, we require that $z > 0$. So, the domain is the set of points (x, y, z) satisfying $z > 0$, or the set $\{(x, y, z) \mid z > 0\}$. This is the part of $\mathbb{R}^3$ that lies strictly above the plane $z = 0$.

10. This is the plane $z = x - y + 5$, or $x - y - z + 5 = 0$, so it has normal vector $\langle 1, -1, -1 \rangle$. Also, it has x -intercept -5 (which we find by setting y, z to 0), y -intercept 5 (which we find by setting x, z to 0), and z -intercept 5 (which we find by setting x, y to 0).

11. In this function, y is an unrestricted variable, so we may sketch the graph by sketching $z = \sin x$ in the xz -plane, and extending freely in y .

12. In this function, y is an unrestricted variable, so we may sketch the graph by sketching $z = \ln x$ in the xz -plane, and extending freely in y .

13. In this function, x is an unrestricted variable, so we may sketch the graph by sketching $z = e^y$ in the yz -plane, and extending freely in x .

14. We set $z = c$, and we get $c = x^2 - 2y$, which is equivalent to $y = \frac{x^2 - c}{2} = \frac{x^2}{2} - \frac{c}{2}$. We recognize these equations; their graphs are parabolas shrunk vertically by a factor of 2, and shifted vertically according to the value of $\frac{c}{2}$. For $c > 0$, they are shifted down $\frac{c}{2}$; for $c < 0$, they are shifted up $\frac{|c|}{2}$.

15. We set $z = c$, and we get $c = \sqrt{x^2 + y^2}$, which is equivalent to $c^2 = x^2 + y^2$. We recognize these equations; their graphs are circles centered at the origin, of radius c (note that c must be nonnegative), for $c \neq 0$. For $c = 0$, the equation becomes $x^2 + y^2 = 0$, which is satisfied only when $x = y = 0$, or at the point $(0, 0)$. So, the level curves for $c = 1, 4$, and 9 are circles of radius c centered at the origin, and the level curve for $c = 0$ is only the origin itself.

16. We set $z = c$, and we get $c = e^{4x^2 + y^2}$, which is equivalent to $\ln c = 4x^2 + y^2$. For $c = 1$, we have $\ln 1 = 4x^2 + y^2$, or $0 = 4x^2 + y^2$, which is satisfied only when $x = y = 0$, or at the point $(0, 0)$. When $c = e^k$ for $k > 0$, we have $\ln(e^k) = 4x^2 + y^2$, or $k = 4x^2 + y^2$. Equivalently:

$$1 = \frac{4x^2}{k} + \frac{y^2}{k}$$

$$1 = \frac{x^2}{k/4} + \frac{y^2}{k}$$

We recognize these equations; their graphs are ellipses centered at the origin, while the level curve for $c = 1$ is only the origin itself.

17. We consider surfaces of the form $f(x, y, z) = c = 4x^2 + y^2 + z^2$, where c is a constant (which in this case, cannot be negative since $4x^2 + y^2 + z^2 \geq 0$ for all x, y, z). Equivalently:

$$1 = \frac{4x^2}{c} + \frac{y^2}{c} + \frac{z^2}{c} \quad \text{if } c \neq 0$$

$$1 = \frac{x^2}{c/4} + \frac{y^2}{c} + \frac{z^2}{c} \quad \text{if } c \neq 0$$

We recognize these surfaces as ellipsoids centered at the origin (if $c \neq 0$), of increasing radii as c increases. If $c = 0$, our level curve has equation $0 = 4x^2 + y^2 + z^2$, which is only satisfied when $(x, y, z) = (0, 0, 0)$. Thus, our level curve for $c = 0$ is the point $(0, 0, 0)$.

One of the level surfaces associated with the function $w = 4x^2 + y^2 + z^2$ is the point $(0, 0, 0)$, and the others are all ellipsoids in space.

18. We consider surfaces of the form $f(x, y, z) = c = x + y + 2z$, where c is a constant. We observe that this surface forms a plane perpendicular to the vector $\langle 1, 1, 2 \rangle$. We can rewrite this surface as $z = -\frac{x}{2} - \frac{y}{2} + \frac{c}{2}$, from which we can see that increasing values of c increase the z -intercept of the plane (i.e. move it up).

19. We use algebraic properties of limits:

$$\lim_{(x,y) \rightarrow (\pi/2, 0)} \frac{\sin x \cos y}{x} = \left(\lim_{x \rightarrow \pi/2} \frac{\sin x}{x} \right) \left(\lim_{y \rightarrow 0} \cos y \right) = \frac{\sin(\frac{\pi}{2})}{\frac{\pi}{2}} \cdot 1 = \frac{1}{\frac{\pi}{2}} = \boxed{\frac{2}{\pi}}.$$

20. Look at the denominator. Since

$$\lim_{(x,y) \rightarrow (1,2)} (2x + y) = \left(\lim_{x \rightarrow 1} 2x \right) + \left(\lim_{y \rightarrow 2} y \right) = 2 + 2 = 4 \neq 0,$$

we can use the limit of a quotient property. Now look at the numerator:

$$\begin{aligned} \lim_{(x,y) \rightarrow (1,2)} (4x^2 + y^2) &= \left(\lim_{x \rightarrow 1} 4x^2 \right) + \left(\lim_{y \rightarrow 2} y^2 \right) \\ &= 4 + 4 = 8. \end{aligned}$$

So, by the limit of a quotient property,

$$\lim_{(x,y) \rightarrow (1,2)} \frac{4x^2 + y^2}{2x + y} = \frac{\lim_{(x,y) \rightarrow (1,2)} (4x^2 + y^2)}{\lim_{(x,y) \rightarrow (1,2)} (2x + y)} = \frac{8}{4} = \boxed{2}.$$

21. (a) We have that, along the lines $y = mx$,

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{3xy^2}{x^2 + y^4} &= \lim_{x \rightarrow 0} \frac{3x(mx)^2}{x^2 + (mx)^4} \\ &= \lim_{x \rightarrow 0} \frac{3m^2x^3}{x^2 + m^4x^4} \\ &= \lim_{x \rightarrow 0} \frac{3m^2x^3}{x^2(1 + m^4x^2)} \\ &= \lim_{x \rightarrow 0} \frac{3m^2x}{1 + m^4x^2} = \frac{0}{1} = 0 \end{aligned}$$

(b) We have that, along the parabola $x = y^2$,

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{3xy^2}{x^2 + y^4} &= \lim_{y \rightarrow 0} \frac{3(y^2)y^2}{(y^2)^2 + y^4} \\ &= \lim_{y \rightarrow 0} \frac{3y^4}{y^4 + y^4} \\ &= \lim_{y \rightarrow 0} \frac{3y^4}{2y^4} \\ &= \lim_{y \rightarrow 0} \frac{3}{2} = \boxed{\frac{3}{2}} \end{aligned}$$

(c) Since the limits differ along different curves containing $(0,0)$, we are forced to conclude that the limit does not exist.

22. We consider the limit along different curves in $\mathbb{R}^3$ that contain the point $(0,0,0)$. We first consider the limit along the x -axis, described by $y = z = 0$:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,0,0)} \frac{4xy}{x^2 + y^2 + z^2} &= \lim_{x \rightarrow 0} \frac{4x(0)}{x^2 + 0^2 + 0^2} \\ &= \lim_{x \rightarrow 0} \frac{0}{x^2} \end{aligned}$$

$$= \lim_{x \rightarrow 0} 0 = 0$$

We now consider the limit along the curve described by $y = x, z = 0$:

$$\begin{aligned} \lim_{(x,y,z) \rightarrow (0,0,0)} \frac{4xy}{x^2 + y^2 + z^2} &= \lim_{x \rightarrow 0} \frac{4x(x)}{x^2 + x^2 + 0^2} \\ &= \lim_{x \rightarrow 0} \frac{4x^2}{2x^2} \\ &= \lim_{x \rightarrow 0} \frac{4}{2} \\ &= \lim_{x \rightarrow 0} 2 = 2 \neq 0 \end{aligned}$$

Since the limits differ along two different curves containing $(0,0,0)$, we are forced to conclude that the limit does not exist.

23. Because this function is a polynomial function, it is continuous at all points (x, y) in the plane.
24. Because this function is a rational function; that is, it is a ratio of polynomial functions, it will be continuous everywhere except where its denominator is 0. So, this function is continuous for all (x, y) such that $x^2 - y^2 \neq 0$. Equivalently, where $x^2 \neq y^2$, or where $x \neq \pm y$. So, this function is continuous on the set $\{(x, y) | x \neq \pm y\}$.
25. (a) This function is a composition of the function $g(t) = \tan^{-1} t$ and $h(x, y) = \frac{1}{x^2 + y^2}$. g is continuous everywhere since $\tan^{-1} t$ is defined for all real numbers t , and so we only need to determine where h is continuous. h is a rational function, so we only need to determine where its denominator is 0. $x^2 + y^2 = 0$ only at the point $(x, y) = (0, 0)$, so h is defined and therefore continuous on the set $\{(x, y) | (x, y) \neq (0, 0)\}$. So, the entire function f is continuous on $\{(x, y) | (x, y) \neq (0, 0)\}$.
- (b) Because $f(x, y) = \tan^{-1} \left(\frac{1}{x^2 + y^2} \right)$ is continuous at $(0, 1)$, we may evaluate the limit by evaluating the function at $(0, 1)$:

$$\lim_{(x,y) \rightarrow (0,1)} \tan^{-1} \left(\frac{1}{x^2 + y^2} \right) = \tan^{-1} \left(\frac{1}{0^2 + 1^2} \right) = \tan^{-1}(1) = \boxed{\frac{\pi}{4}}.$$

$$\begin{aligned} 26. \quad f_x &= e^{x^2+y^2} (2x) \sin(xy) + e^{x^2+y^2} \cos(xy)(y) \\ &= 2xe^{x^2+y^2} \sin(xy) + ye^{x^2+y^2} \cos(xy) \\ &= e^{x^2+y^2} [2x \sin(xy) + y \cos(xy)] \end{aligned}$$

and

$$\begin{aligned} f_y &= e^{x^2+y^2} (2y) \sin(xy) + e^{x^2+y^2} \cos(xy)(x) \\ &= 2ye^{x^2+y^2} \sin(xy) + xe^{x^2+y^2} \cos(xy) \\ &= e^{x^2+y^2} [2y \sin(xy) + x \cos(xy)] \end{aligned}$$

$$\text{so } \boxed{f_x = e^{x^2+y^2} [2x \sin(xy) + y \cos(xy)]} \text{ and } \boxed{f_y = e^{x^2+y^2} [2y \sin(xy) + x \cos(xy)]}.$$

27. We first rewrite the function as $f(x, y) = \frac{x+y}{y} = \frac{x}{y} + 1$ to simplify the computations. Then,

$$f_x = \frac{1}{y}$$

and

$$f_y = x(-y^{-2}) = -\frac{x}{y^2}$$

$$\text{so, } \boxed{f_x = \frac{1}{y}} \text{ and } \boxed{f_y = -\frac{x}{y^2}}.$$

28. We have that

$$\frac{\partial z}{\partial x} = \frac{1}{2}(x - 2y^2)^{-1/2}(1) = \frac{1}{2\sqrt{x - 2y^2}}$$

and

$$\frac{\partial z}{\partial y} = \frac{1}{2}(x - 2y^2)^{-1/2}(-4y) = \frac{-4y}{2\sqrt{x - 2y^2}} = \frac{-2y}{\sqrt{x - 2y^2}}$$

$$\text{So, } \boxed{\frac{\partial z}{\partial x} = \frac{1}{2\sqrt{x - 2y^2}}} \text{ and } \boxed{\frac{\partial z}{\partial y} = \frac{-2y}{\sqrt{x - 2y^2}}}.$$

29. We have that

$$\frac{\partial z}{\partial x} = e^x \ln(5x + 2y) + e^x \frac{1}{5x + 2y}(5) = e^x \left[\ln(5x + 2y) + \frac{5}{5x + 2y} \right]$$

and

$$\frac{\partial z}{\partial y} = e^x \frac{1}{5x + 2y}(2) = \frac{2e^x}{5x + 2y}$$

$$\text{So, } \boxed{\frac{\partial z}{\partial x} = e^x \left[\ln(5x + 2y) + \frac{5}{5x + 2y} \right]} \text{ and } \boxed{\frac{\partial z}{\partial y} = \frac{2e^x}{5x + 2y}}.$$

30. We first compute $f_x(x, y)$ and $f_y(x, y)$ and then evaluate these at $(2, 1)$ and $(2, -1)$ respectively.

$$f_x = \frac{1}{2}(x^2 - y^2)^{-1/2}(2x) = \frac{x}{\sqrt{x^2 - y^2}}$$

$$f_x(2, 1) = \frac{2}{\sqrt{2^2 - 1^2}} = \frac{2}{\sqrt{3}} = \frac{2\sqrt{3}}{3}.$$

And

$$f_y = \frac{1}{2}(x^2 - y^2)^{-1/2}(-2y) = \frac{-y}{\sqrt{x^2 - y^2}}$$

$$f_y(2, -1) = \frac{-(-1)}{\sqrt{2^2 - (-1)^2}} = \frac{1}{\sqrt{3}} = \frac{\sqrt{3}}{3}.$$

$$\text{So, } \boxed{f_x(2, 1) = f_y(2, -1) = \frac{2\sqrt{3}}{3}}.$$

31. We first compute $F_x(x, y)$ and $F_y(x, y)$ and then evaluate each of these at $\left(0, \frac{\pi}{6}\right)$.

$$F_x = e^x \sin y$$

$$F_x\left(0, \frac{\pi}{6}\right) = e^0 \sin \frac{\pi}{6} = (1) \left(\frac{1}{2}\right) = \frac{1}{2}.$$

Also,

$$F_y = e^x \cos y$$

$$F_y\left(0, \frac{\pi}{6}\right) = e^0 \cos \frac{\pi}{6} = (1) \left(\frac{\sqrt{3}}{2}\right) = \frac{\sqrt{3}}{2}.$$

$$\text{So, } \boxed{F_x\left(0, \frac{\pi}{6}\right) = \frac{1}{2}} \text{ and } \boxed{F_y\left(0, \frac{\pi}{6}\right) = \frac{\sqrt{3}}{2}}.$$

32. The slope of the tangent line to the curve of intersection of $\frac{x^2}{24} + \frac{y^2}{12} + \frac{z^2}{6} = 1$ and $y = 1$, where $x = 4$ and $z > 0$, can be found by first solving our equation for z and then finding its partial derivative with respect to x :

$$\frac{x^2}{24} + \frac{y^2}{12} + \frac{z^2}{6} = 1$$

$$\frac{z^2}{6} = 1 - \frac{x^2}{24} - \frac{y^2}{12}$$

$$z^2 = 6 - \frac{x^2}{4} - \frac{y^2}{2}$$

$$z = \pm \sqrt{6 - \frac{x^2}{4} - \frac{y^2}{2}}$$

Because we were told to consider $z > 0$, we take the positive square root, or

$$z = \sqrt{6 - \frac{x^2}{4} - \frac{y^2}{2}} = f(x, y). \text{ Then,}$$

$$f_x(x, 1) = \frac{1}{2} \left(6 - \frac{x^2}{4} - \frac{1^2}{2}\right)^{-1/2} \left(-\frac{2x}{4}\right) = \frac{-x}{4\sqrt{\frac{11}{2} - \frac{x^2}{4}}} = \frac{-x}{4\sqrt{\frac{22 - x^2}{4}}} = \frac{-x}{4\frac{\sqrt{22 - x^2}}{2}} = \frac{-x}{2\sqrt{22 - x^2}}$$

so

at $x = 4$, the slope is $\frac{-4}{2\sqrt{22 - 4^2}} = \frac{-2}{\sqrt{6}}$. This tangent line lies on the plane $y = 1$, and when $x = 4, y = 1$, we have $z = \sqrt{6 - \frac{4^2}{4} - \frac{1^2}{2}} = \sqrt{2 - \frac{1}{2}} = \sqrt{\frac{3}{2}}$. Symmetric equations of the tangent line are then

$$\frac{z - \sqrt{\frac{3}{2}}}{1} = \frac{x - 4}{-\frac{\sqrt{6}}{2}} \quad y = 1$$

33. (a) The slope of the tangent line to the curve of intersection of $z = 4x^2 - y^2 + 7$ and $y = -2$ at any point is $f_x(x, -2) = 8x$. At the point $(1, -2, 7)$, the slope is 8. This tangent line lies on the plane $y = -2$. Symmetric equations of the tangent line are

$$\frac{z - 7}{1} = \frac{x - 1}{\frac{1}{8}} \quad y = -2$$

- (b) The slope of the tangent line to the curve of intersection of $z = 4x^2 - y^2 + 7$ and $x = 1$ at any point is $f_y(1, y) = -2y$. At the point $(1, -2, 7)$, the slope is 4. This tangent line lies on the plane $x = 1$. Symmetric equations of the tangent line are

$$\frac{z - 7}{1} = \frac{y + 2}{\frac{1}{4}} \quad x = 1$$

34. Since it is stated that V varies directly with T and inversely with P , we can write that $V = k \frac{T}{P}$ for some constant k . We use this to answer the following questions.

- (a) The rate of change of V with respect to T is given by the partial derivative of V with respect to

$$T, V_T. \text{ We have that } V_T = k \left(\frac{1}{P} \right).$$

- (b) The rate of change of V with respect to P is given by the partial derivative of V with respect to

$$P, V_P. \text{ We have that } V_P = kT(-P^{-2}) = -k \left(\frac{T}{P^2} \right), \text{ so } V_P = -k \left(\frac{T}{P^2} \right).$$

- (c) We use Chain Rule I to find $\frac{dV}{dt}$. Since V depends on P and T , which in turn each depend on t , we have that

$$\frac{dV}{dt} = \frac{\partial V}{\partial P} \frac{dP}{dt} + \frac{\partial V}{\partial T} \frac{dT}{dt}.$$

35. $f_x = (1)e^{3x} + (x + y^2)e^{3x} \cdot 3 = e^{3x} + 3(x + y^2)e^{3x}$

$$f_{xx} = 3e^{3x} + 3[(1)e^{3x} + (x + y^2)e^{3x} \cdot 3] = 3e^{3x} + 3e^{3x} + 9(x + y^2)e^{3x} = 6e^{3x} + 9(x + y^2)e^{3x}$$

$$f_{xx} = 6e^{3x} + 9(x + y^2)e^{3x}$$

$$f_{xy} = 3(2y)e^{3x} = 6ye^{3x}$$

$$f_{xy} = 6ye^{3x}$$

$$f_y = 2ye^{3x}$$

$$f_{yx} = 2ye^{3x} \cdot 3 = 6ye^{3x}$$

$$\boxed{f_{yx} = 6ye^{3x}} \text{ (note that this is equal to } f_{xy} \text{)}$$

$$\boxed{f_{yy} = 2e^{3x}}$$

36. $f_x = \sec(xy) \tan(xy) \cdot y = y \sec(xy) \tan(xy)$

$$f_{xx} = [y \sec(xy) \tan(xy) \cdot y] \tan(xy) + [y \sec(xy)] \sec^2(xy) \cdot y = y^2 \sec(xy) \tan^2(xy) + y^2 \sec^3(xy)$$

$$\boxed{f_{xx} = y^2 \sec(xy) \tan^2(xy) + y^2 \sec^3(xy)}$$

$$f_{xy} = [\sec(xy) + y \sec(xy) \tan(xy) \cdot x] \tan(xy) + y \sec(xy) \sec^2(xy) \cdot x \\ = \sec(xy) \tan(xy) + xy \sec(xy) \tan^2(xy) + xy \sec^3(xy)$$

$$\boxed{f_{xy} = \sec(xy) \tan(xy) + xy \sec(xy) \tan^2(xy) + xy \sec^3(xy)}$$

To find f_{yx} , it is easiest to note that by Clairaut's Theorem,

$$f_{yx} = f_{xy} = \sec(xy) \tan(xy) + xy \sec(xy) \tan^2(xy) + xy \sec^3(xy), \text{ and so}$$

$$\boxed{f_{yx} = \sec(xy) \tan(xy) + xy \sec(xy) \tan^2(xy) + xy \sec^3(xy)}$$

$$f_y = \sec(xy) \tan(xy) \cdot x = x \sec(xy) \tan(xy)$$

$$f_{yy} = [x \sec(xy) \tan(xy) \cdot x] \tan(xy) + [x \sec(xy)] \sec^2(xy) \cdot x = x^2 \sec(xy) \tan^2(xy) + x^2 \sec^3(xy)$$

$$\boxed{f_{yy} = x^2 \sec(xy) \tan^2(xy) + x^2 \sec^3(xy)}$$

37. $f_x = e^{xyz}(yz)$

$$\boxed{f_x = yze^{xyz}}$$

$$f_y = e^{xyz}(xz)$$

$$\boxed{f_y = xze^{xyz}}$$

$$f_z = e^{xyz}(xy)$$

$$\boxed{f_z = xye^{xyz}}$$

38. $f_x = ze^{xy} \cdot y$

$$\boxed{f_x = yze^{xy}}$$

$$f_y = ze^{xy} \cdot x$$

$$\boxed{f_y = xze^{xy}}$$

$$\boxed{f_z = e^{xy}}$$

39. $f_x = e^x \sin y$

$$f_y = e^x \cos y + e^y \sin z$$

$$f_z = e^y \cos z$$

40. $f_x = z \left(\frac{1}{1 + \left(\frac{y}{x}\right)^2} \right) \cdot y(-x^{-2})$

$$= \frac{-yz}{x^2 \left(1 + \frac{y^2}{x^2}\right)} = \frac{-yz}{x^2 + y^2}$$

$$f_x = \frac{-yz}{x^2 + y^2}$$

$$f_y = z \left(\frac{1}{1 + \left(\frac{y}{x}\right)^2} \right) \cdot \frac{1}{x}$$

$$= \frac{z}{x \left(1 + \frac{y^2}{x^2}\right)} = \frac{z}{x + \frac{y^2}{x}} = \frac{xz}{x^2 + y^2}$$

$$f_y = \frac{xz}{x^2 + y^2}$$

$$f_z = \tan^{-1} \left(\frac{y}{x} \right)$$

41. We first compute $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$:

$$\frac{\partial z}{\partial x} = 3x^2y^2 - 2y^4 + 6xy^3$$

$$\frac{\partial z}{\partial y} = 2x^3y - 8xy^3 + 9x^2y^2$$

We now evaluate $x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y}$ using these:

$$\begin{aligned} x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} &= x(3x^2y^2 - 2y^4 + 6xy^3) + y(2x^3y - 8xy^3 + 9x^2y^2) \\ &= 3x^3y^2 - 2xy^4 + 6x^2y^3 + 2x^3y^2 - 8xy^4 + 9x^2y^3 \\ &= 5x^3y^2 - 10xy^4 + 15x^2y^3 \\ &= 5(x^3y^2 - 2xy^4 + 3x^2y^3) = 5z \quad \checkmark \end{aligned}$$

42. We have that the change in z , Δz , is given by $f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0)$, which we compute as follows:

$$f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0) = (x_0 + \Delta x)(y_0 + \Delta y)^2 + 2 - (x_0y_0^2 + 2)$$

$$\begin{aligned}
&= (x_0 + \Delta x)(y_0^2 + 2y_0\Delta y + (\Delta y)^2) + 2 - x_0y_0^2 - 2 \\
&= x_0y_0^2 + 2x_0y_0\Delta y + x_0(\Delta y)^2 + y_0^2\Delta x + 2y_0\Delta x\Delta y + \Delta x(\Delta y)^2 - x_0y_0^2 \\
&= 2x_0y_0\Delta y + x_0(\Delta y)^2 + y_0^2\Delta x + 2y_0\Delta x\Delta y + \Delta x(\Delta y)^2
\end{aligned}$$

So $\boxed{\Delta z = 2x_0y_0\Delta y + x_0(\Delta y)^2 + y_0^2\Delta x + 2y_0\Delta x\Delta y + \Delta x(\Delta y)^2}$.

We use this answer to calculate the change in z from $(1,0)$ to $(0.9,0.2)$, which yield $x_0 = 1, y_0 = 0, \Delta x = 0.9 - 1 = -0.1, \Delta y = 0.2 - 0 = 0.2$:

$$\begin{aligned}
\Delta z &= 2(1)(0)(0.2) + (1)(0.2)^2 + (0)^2(-0.1) + 2(0)(-0.1)(0.2) + (-0.1)(0.2)^2 \\
&= 0.04 - 0.004 = 0.036
\end{aligned}$$

So, $\boxed{\Delta z = 0.036}$.

43. (a) We have that the change in z , Δz , is given by $f(x + \Delta x, y + \Delta y) - f(x, y)$, which we compute as follows:

$$\begin{aligned}
f(x + \Delta x, y + \Delta y) - f(x, y) &= (x + \Delta x)(y + \Delta y) - 5(y + \Delta y)^2 - (xy - 5y^2) \\
&= xy + x\Delta y + y\Delta x + \Delta x\Delta y - 5(y^2 + 2y\Delta y + (\Delta y)^2) - xy + 5y^2 \\
&= xy + x\Delta y + y\Delta x + \Delta x\Delta y - 5y^2 - 10y\Delta y - 5(\Delta y)^2 - xy + 5y^2 \\
&= x\Delta y + y\Delta x + \Delta x\Delta y - 10y\Delta y - 5(\Delta y)^2 \\
&= y\Delta x + (x - 10y)\Delta y + (\Delta y)\Delta x + (-5\Delta y)\Delta y
\end{aligned}$$

So, $\boxed{\Delta z = y\Delta x + (x - 10y)\Delta y + (\Delta y)\Delta x + (-5\Delta y)\Delta y}$.

- (b) Note that $f_x(x, y) = y$ and $f_y(x, y) = x - 10y$. So, we see from our manipulations from part (a) that we may choose η_1 and η_2 as follows:

$$\boxed{\eta_1 = \Delta y}$$

$$\boxed{\eta_2 = -5\Delta y},$$

which will yield $\Delta z = y\Delta x + (x - 10y)\Delta y + \eta_1\Delta x + \eta_2\Delta y$. (Note that had we rearranged Δz differently in part (a), we may have had a different choice of η_1 and η_2 .)

- (c) We now show that $\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_1 = 0$ and $\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_2 = 0$. We have that

$$\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_1 = \lim_{\Delta y \rightarrow 0} \Delta y = 0$$

and

$$\lim_{(\Delta x, \Delta y) \rightarrow (0,0)} \eta_2 = \lim_{\Delta y \rightarrow 0} -5\Delta y = 0.$$

44. The differential dz is given by $dz = f_x(x, y)dx + f_y(x, y)dy$. So, we compute $f_x(x, y)$ and $f_y(x, y)$:
 $f_x(x, y) = \sqrt{1 + y^2}$

and

$$f_y(x, y) = x \left[\frac{1}{2}(1 + y^2)^{-1/2}(2y) \right] = \frac{xy}{\sqrt{1 + y^2}}$$

so, we have that $\boxed{dz = \sqrt{1 + y^2} dx + \frac{xy}{\sqrt{1 + y^2}} dy}.$

45. The differential dz is given by $dz = f_x(x, y)dx + f_y(x, y)dy$. So, we compute $f_x(x, y)$ and $f_y(x, y)$:

$$f_x(x, y) = \frac{1}{\sqrt{1 - \left(\frac{x}{y}\right)^2}} \cdot \frac{1}{y}$$

$$= \frac{1}{y\sqrt{1 - \frac{x^2}{y^2}}} = \frac{1}{\sqrt{y^2 \left(1 - \frac{x^2}{y^2}\right)}} \quad \text{since } y > 0$$

$$= \frac{1}{\sqrt{y^2 - x^2}}$$

and

$$f_y(x, y) = \frac{1}{\sqrt{1 - \left(\frac{x}{y}\right)^2}} \cdot x(-y^{-2})$$

$$= \frac{-x}{y^2\sqrt{1 - \frac{x^2}{y^2}}} = \frac{-x}{y\sqrt{y^2 \left(1 - \frac{x^2}{y^2}\right)}} \quad \text{since } y > 0$$

$$= \frac{-x}{y\sqrt{y^2 - x^2}}$$

so, we have that $\boxed{dz = \frac{1}{\sqrt{y^2 - x^2}} dx + \frac{-x}{y\sqrt{y^2 - x^2}} dy}.$

46. The differential dw is given by $dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$. Therefore, we compute $f_x(x, y, z)$, $f_y(x, y, z)$, and $f_z(x, y, z)$:

$$f_x(x, y, z) = ze^{xy} \cdot y = yze^{xy}$$

and

$$f_y(x, y, z) = ze^{xy} \cdot x = xze^{xy}$$

and

$$f_z(x, y, z) = e^{xy}$$

so, we have that $\boxed{dw = yze^{xy} dx + xze^{xy} dy + e^{xy} dz}$.

47. The function f is defined everywhere in space except the surface $xyz = 0$. The differential dw is given by $dw = f_x(x, y, z)dx + f_y(x, y, z)dy + f_z(x, y, z)dz$. Therefore, we compute $f_x(x, y, z)$, $f_y(x, y, z)$, and $f_z(x, y, z)$.

$$f_x(x, y, z) = \frac{1}{xyz}(yz) = \frac{1}{x}$$

and

$$f_y(x, y, z) = \frac{1}{xyz}(xz) = \frac{1}{y}$$

and

$$f_z(x, y, z) = \frac{1}{xyz}(xy) = \frac{1}{z}$$

so, we have that $\boxed{dw = \frac{1}{x} dx + \frac{1}{y} dy + \frac{1}{z} dz}$.

48. We compute the differential dz for the function $z = f(x, y) = x\sqrt{1+y^2}$ by first finding its partial derivatives at the point $(x_0, y_0) = (4, 0)$:

$$\begin{aligned} f_x(x, y) &= \sqrt{1+y^2} \\ f_x(4, 0) &= \sqrt{1+0^2} = 1 \end{aligned}$$

$$f_y(x, y) = x \left[\frac{1}{2}(1+y^2)^{-1/2}(2y) \right] = \frac{xy}{\sqrt{1+y^2}}$$

$$f_y(4, 0) = \frac{(4)(0)}{\sqrt{1+0^2}} = 0$$

Also, $dx = \Delta x = 4.1 - 4 = 0.1$ and $dy = \Delta y = 0.1 - 0 = 0.1$. The differential is given by

$$\begin{aligned} dz &= f_x(4, 0)dx + f_y(4, 0)dy \\ &= 1(0.1) + 0(0.1) \\ &= 0.1. \end{aligned}$$

So, the change in z is approximately $\boxed{0.1}$.

49. We compute the differential dz for the function $z = f(x, y) = \sin^{-1}\left(\frac{x}{y}\right)$ by first finding its partial derivatives at the point $(x_0, y_0) = (0, 1)$:

$$f_x(x, y) = \frac{1}{\sqrt{1 - \left(\frac{x}{y}\right)^2}} \cdot \frac{1}{y}$$

$$\begin{aligned}
&= \frac{1}{y\sqrt{1-\frac{x^2}{y^2}}} = \frac{1}{\sqrt{y^2\left(1-\frac{x^2}{y^2}\right)}} \quad \text{since } y > 0 \\
&= \frac{1}{\sqrt{y^2-x^2}} \\
f_x(0,1) &= \frac{1}{\sqrt{1^2-0^2}} = 1 \\
f_y(x,y) &= \frac{1}{\sqrt{1-\left(\frac{x}{y}\right)^2}} \cdot x(-y^{-2}) \\
&= \frac{-x}{y^2\sqrt{1-\frac{x^2}{y^2}}} = \frac{-x}{y\sqrt{y^2\left(1-\frac{x^2}{y^2}\right)}} \quad \text{since } y > 0 \\
&= \frac{-x}{y\sqrt{y^2-x^2}} \\
f_y(0,1) &= \frac{-0}{1\sqrt{1^2-0^2}} = 0
\end{aligned}$$

Also, $dx = \Delta x = 0.1 - 0 = 0.1$ and $dy = \Delta y = 1.1 - 1 = 0.1$. The differential is given by

$$\begin{aligned}
dz &= f_x(0,1)dx + f_y(0,1)dy \\
&= 1(0.1) + 0(0.1) \\
&= 0.1.
\end{aligned}$$

So, the change in z is approximately $\boxed{0.1}$.

50. We observe that we can approximate $f(0.05, 1.98)$ by approximating the change in z from $(0,2)$ to $(0.05, 1.98)$ using the differential. So we compute, for the function $z = f(x, y) = y^2 \cos x$, the differential $dz = f_x(0, 2)dx + f_y(0, 2)dy$. We start by finding the partial derivatives f_x and f_y at the point $(0, 2)$:

$$\begin{aligned}
f_x(x, y) &= y^2(-\sin x) = -y^2 \sin x \\
f_x(0, 2) &= -2^2 \sin 0 = (-4)(0) = 0
\end{aligned}$$

and

$$\begin{aligned}
f_y(x, y) &= 2y \cos x \\
f_y(0, 2) &= 2(2) \cos 0 = (4)(1) = 4.
\end{aligned}$$

Also, $dx = \Delta x = 0.05 - 0 = 0.05$ and $dy = \Delta y = 1.98 - 2 = -0.02$. So, the change in z from $(0, 2)$ to $(0.05, 1.98)$ is approximately equal to the differential:

$$\begin{aligned}
dz &= f_x(0, 2)dx + f_y(0, 2)dy \\
&= 0(0.05) + 4(-0.02) \\
&= -0.08.
\end{aligned}$$

We can then approximate $f(0.05, 1.98)$ by adding the approximate change in z (-0.08) to the value of $f(0, 2) = 2^2 \cos 0 = 4$. This yields that $f(0.05, 1.98) \approx 4 + (-0.08) = 3.92$. So $\boxed{f(0.05, 1.98) \approx 3.92}$.

51. We approximate the maximum variation of the total resistance R by using the differential dR . Note that $\frac{|\Delta L|}{L} = \frac{|dL|}{L} = 0.01$ and $\frac{|\Delta D|}{D} = \frac{|dD|}{D} = 0.02$.

$$\begin{aligned} \text{We have that } \frac{|\Delta R|}{R} &\approx \frac{|dR|}{R} = \frac{\left| \frac{k}{D^2} dL + \frac{-2kL}{D^3} dD \right|}{\frac{kL}{D^2}} \leq \frac{\left| \frac{k}{D^2} dL \right|}{\frac{kL}{D^2}} + \frac{\left| \frac{2kL}{D^3} dD \right|}{\frac{kL}{D^2}} \\ &= \frac{|dL|}{L} + 2 \frac{|dD|}{D} \\ &= 0.01 + 2(0.02) = 0.05. \end{aligned}$$

So, the maximum variation of the total resistance R is $\boxed{\approx 5\%}$

52. We compute $\frac{dz}{dt}$ by applying Chain Rule I. Since z is a function of x and y , which are in turn each functions of t , we have the following:

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt}$$

We compute the four required derivatives:

$$\frac{\partial z}{\partial x} = \cos(xy) \cdot y - \sin y = y \cos(xy) - \sin y$$

$$\frac{\partial z}{\partial y} = \cos(xy) \cdot x - x \cos y = x \cos(xy) - x \cos y$$

$$\frac{dx}{dt} = e^t$$

$$\frac{dy}{dt} = (1)e^t + te^t = e^t + te^t$$

So then

$$\begin{aligned} \frac{dz}{dt} &= \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt} \\ &= (y \cos(xy) - \sin y)e^t + (x \cos(xy) - x \cos y)(e^t + te^t) \\ &= [(te^t) \cos(e^t \cdot te^t) - \sin(te^t)]e^t + [e^t \cos(e^t \cdot te^t) - (e^t) \cos(te^t)](e^t + te^t) \\ &= te^{2t} \cos(te^{2t}) - e^t \sin(te^t) + e^{2t} \cos(te^{2t}) + te^{2t} \cos(te^{2t}) - e^{2t} \cos(te^t) - te^{2t} \cos(te^t) \\ &= 2te^{2t} \cos(te^{2t}) - e^t \sin(te^t) + e^{2t} \cos(te^{2t}) - e^{2t} \cos(te^t) - te^{2t} \cos(te^t) \end{aligned}$$

$$\text{So, } \boxed{\frac{dz}{dt} = 2te^{2t} \cos(te^{2t}) - e^t \sin(te^t) + e^{2t} \cos(te^{2t}) - e^{2t} \cos(te^t) - te^{2t} \cos(te^t)}.$$

53. We compute $\frac{dw}{dt}$ by applying Chain Rule I. Since W is a function of x, y , and z , which are in turn each functions of t , we have the following:

$$\frac{dw}{dt} = \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} + \frac{\partial w}{\partial z} \frac{dz}{dt}$$

We compute the six required derivatives:

$$\frac{\partial w}{\partial x} = \frac{1}{y} + z(-x^{-2}) = \frac{1}{y} - \frac{z}{x^2}$$

$$\frac{\partial w}{\partial y} = x(-y^{-2}) + \frac{1}{z} = -\frac{x}{y^2} + \frac{1}{z}$$

$$\frac{\partial w}{\partial z} = y(-z^{-2}) + \frac{1}{x} = -\frac{y}{z^2} + \frac{1}{x}$$

$$\frac{dx}{dt} = -t^{-2} = -\frac{1}{t^2}$$

$$\frac{dy}{dt} = -2t^{-3} = -\frac{2}{t^3}$$

$$\frac{dz}{dt} = -3t^{-4} = -\frac{3}{t^4}$$

So then

$$\begin{aligned} \frac{dw}{dt} &= \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} + \frac{\partial w}{\partial z} \frac{dz}{dt} \\ &= \left(\frac{1}{y} - \frac{z}{x^2} \right) \left(-\frac{1}{t^2} \right) + \left(-\frac{x}{y^2} + \frac{1}{z} \right) \left(-\frac{2}{t^3} \right) + \left(-\frac{y}{z^2} + \frac{1}{x} \right) \left(-\frac{3}{t^4} \right) \\ &= \left(\frac{1}{\frac{1}{t^2}} - \frac{\frac{1}{t^3}}{\left(\frac{1}{t} \right)^2} \right) \left(-\frac{1}{t^2} \right) + \left(-\frac{\frac{1}{t}}{\left(\frac{1}{t^2} \right)^2} + \frac{1}{\frac{1}{t^3}} \right) \left(-\frac{2}{t^3} \right) + \left(-\frac{\frac{1}{t^2}}{\left(\frac{1}{t^3} \right)^2} + \frac{1}{\frac{1}{t}} \right) \left(-\frac{3}{t^4} \right) \\ &= \left(t^2 - \frac{1}{t} \right) \left(-\frac{1}{t^2} \right) + (-t^3 + t^3) \left(-\frac{2}{t^3} \right) + (-t^4 + t) \left(-\frac{3}{t^4} \right) \\ &= -1 + \frac{1}{t^3} + 0 + 3 - \frac{3}{t^3} = 2 - \frac{2}{t^3} \end{aligned}$$

$$\text{So, } \boxed{\frac{dw}{dt} = \left(\frac{1}{y} - \frac{z}{x^2} \right) \left(-\frac{1}{t^2} \right) + \left(-\frac{x}{y^2} + \frac{1}{z} \right) \left(-\frac{2}{t^3} \right) + \left(-\frac{y}{z^2} + \frac{1}{x} \right) \left(-\frac{3}{t^4} \right) = 2 - \frac{2}{t^3}}.$$

54. We compute $\frac{\partial w}{\partial u}$ and $\frac{\partial w}{\partial v}$ by applying Chain Rule II. Since w is a function of x, y , and z , which are in turn each functions of u and v , we have the following:

$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial u} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial u}$$

and

$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial v} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial v}$$

We compute the nine required derivatives:

$$\frac{\partial w}{\partial x} = y - z$$

$$\frac{\partial w}{\partial y} = x + z$$

$$\frac{\partial w}{\partial z} = y - x$$

$$\frac{\partial x}{\partial u} = 1$$

$$\frac{\partial y}{\partial u} = v$$

$$\frac{\partial z}{\partial u} = 0$$

$$\frac{\partial x}{\partial v} = 1$$

$$\frac{\partial y}{\partial v} = u$$

$$\frac{\partial z}{\partial v} = 1$$

So then

$$\begin{aligned}\frac{\partial w}{\partial u} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial u} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial u} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial u} \\ &= (y - z)(1) + (x + z)(v) + (y - x)(0) = y - z + xv + zv \\ &= uv - v + (u + v)v + (v)v = uv - v + uv + v^2 + v^2 \\ &= 2uv + 2v^2 - v\end{aligned}$$

$$\text{So, } \boxed{\frac{\partial w}{\partial u} = (y - z) + (x + z)(v) = 2uv + 2v^2 - v}. \text{ Also,}$$

$$\begin{aligned}\frac{\partial w}{\partial v} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial v} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial v} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial v} \\ &= (y - z)(1) + (x + z)(u) + (y - x)(1) = y - z + xu + zu + y - x \\ &= 2y - x - z + xu + zu = 2uv - (u + v) - v + (u + v)u + vu \\ &= 2uv - u - v - v + u^2 + uv + uv = 4uv - u - 2v + u^2\end{aligned}$$

$$\text{So, } \boxed{\frac{\partial w}{\partial v} = (y - z) + (x + z)(u) + (y - x) = 4uv - u - 2v + u^2}.$$

55. We compute $\frac{\partial u}{\partial r}$ and $\frac{\partial u}{\partial s}$ by applying Chain Rule II. Since u is a function of x, y , and z , which are in turn each functions of r and s , we have the following:

$$\frac{\partial u}{\partial r} = \frac{\partial u}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial r} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial r}$$

and

$$\frac{\partial u}{\partial s} = \frac{\partial u}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial s} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial s}$$

We compute the nine required derivatives:

$$\frac{\partial u}{\partial x} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2}(2x) = \frac{x}{\sqrt{x^2 + y^2 + z^2}}$$

$$\frac{\partial u}{\partial y} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2}(2y) = \frac{y}{\sqrt{x^2 + y^2 + z^2}}$$

$$\frac{\partial u}{\partial z} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2}(2z) = \frac{z}{\sqrt{x^2 + y^2 + z^2}}$$

$$\frac{\partial x}{\partial r} = \cos s$$

$$\frac{\partial y}{\partial r} = \sin s$$

$$\frac{\partial z}{\partial r} = \frac{1}{2}(r^2 + s^2)^{-1/2}(2r) = \frac{r}{\sqrt{r^2 + s^2}}$$

$$\frac{\partial x}{\partial s} = -r \sin s$$

$$\frac{\partial y}{\partial s} = r \cos s$$

$$\frac{\partial z}{\partial s} = \frac{1}{2}(r^2 + s^2)^{-1/2}(2s) = \frac{s}{\sqrt{r^2 + s^2}}$$

So then

$$\begin{aligned} \frac{\partial u}{\partial r} &= \frac{\partial u}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial r} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial r} \\ &= \frac{x}{\sqrt{x^2 + y^2 + z^2}} \cos s + \frac{y}{\sqrt{x^2 + y^2 + z^2}} \sin s + \frac{z}{\sqrt{x^2 + y^2 + z^2}} \frac{r}{\sqrt{r^2 + s^2}} \\ &= \frac{1}{\sqrt{x^2 + y^2 + z^2}} \left[x \cos s + y \sin s + z \frac{r}{\sqrt{r^2 + s^2}} \right] \\ &= \frac{1}{\sqrt{(r \cos s)^2 + (r \sin s)^2 + (\sqrt{r^2 + s^2})^2}} \left[r \cos s \cos s + r \sin s \sin s + \sqrt{r^2 + s^2} \frac{r}{\sqrt{r^2 + s^2}} \right] \\ &= \frac{1}{\sqrt{r^2 \cos^2 s + r^2 \sin^2 s + r^2 + s^2}} [r \cos^2 s + r \sin^2 s + r] \end{aligned}$$

$$\begin{aligned}
&= \frac{1}{\sqrt{r^2(\cos^2 s + \sin^2 s) + r^2 + s^2}} [r(\cos^2 s + \sin^2 s) + r] \\
&= \frac{1}{\sqrt{r^2 + r^2 + s^2}} (2r) \\
&= \frac{1}{\sqrt{2r^2 + s^2}} (2r) \\
&= \frac{2r}{\sqrt{2r^2 + s^2}} \\
\text{So, } \boxed{\frac{\partial u}{\partial r} = \frac{x}{\sqrt{x^2 + y^2 + z^2}} \cos s + \frac{y}{\sqrt{x^2 + y^2 + z^2}} \sin s + \frac{z}{\sqrt{x^2 + y^2 + z^2}} \frac{r}{\sqrt{r^2 + s^2}} = \frac{2r}{\sqrt{2r^2 + s^2}}}.
\end{aligned}$$

Also,

$$\begin{aligned}
\frac{\partial u}{\partial s} &= \frac{\partial u}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial s} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial s} \\
&= \frac{x}{\sqrt{x^2 + y^2 + z^2}} (-r \sin s) + \frac{y}{\sqrt{x^2 + y^2 + z^2}} (r \cos s) + \frac{z}{\sqrt{x^2 + y^2 + z^2}} \frac{s}{\sqrt{r^2 + s^2}} \\
&= \frac{1}{\sqrt{x^2 + y^2 + z^2}} \left[-xr \sin s + yr \cos s + z \frac{s}{\sqrt{r^2 + s^2}} \right] \\
&= \frac{1}{\sqrt{(r \cos s)^2 + (r \sin s)^2 + (\sqrt{r^2 + s^2})^2}} \left[-r \cos s \cdot r \sin s + r \sin s \cdot r \cos s + \sqrt{r^2 + s^2} \frac{s}{\sqrt{r^2 + s^2}} \right] \\
&= \frac{1}{\sqrt{r^2 \cos^2 s + r^2 \sin^2 s + r^2 + s^2}} (s) \\
&= \frac{s}{\sqrt{r^2(\cos^2 s + \sin^2 s) + r^2 + s^2}} \\
&= \frac{s}{\sqrt{r^2 + r^2 + s^2}} \\
&= \frac{s}{\sqrt{2r^2 + s^2}} \\
\text{So, } \boxed{\frac{\partial u}{\partial s} = \frac{x}{\sqrt{x^2 + y^2 + z^2}} (-r \sin s) + \frac{y}{\sqrt{x^2 + y^2 + z^2}} (r \cos s) + \frac{z}{\sqrt{x^2 + y^2 + z^2}} \frac{s}{\sqrt{r^2 + s^2}} = \frac{s}{\sqrt{2r^2 + s^2}}}.
\end{aligned}$$

56. First, we find the partial derivatives of F :

$$F_x = 2x - 2yz, F_y = 2y - 2xz \text{ and } F_z = -2xy.$$

Then we use Implicit Differentiation Formulas II. If $-2xy \neq 0$,

$$\begin{aligned}
\frac{\partial z}{\partial x} &= -\frac{F_x}{F_z} = -\frac{2x - 2yz}{-2xy} \\
\frac{\partial z}{\partial y} &= -\frac{F_y}{F_z} = -\frac{2y - 2xz}{-2xy}
\end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = \frac{2x - 2yz}{2xy}}$$

$$\boxed{\frac{\partial z}{\partial y} = \frac{2y - 2xz}{2xy}}$$

57. First, we find the partial derivatives of F :

$$F_x = 2 \sin y + 2y \cos x + 2yz, F_y = 2x \cos y + 2 \sin x + 2xz \text{ and } F_z = 2xy.$$

Then we use Implicit Differentiation Formulas II. If $2xy \neq 0$,

$$\begin{aligned} \frac{\partial z}{\partial x} &= -\frac{F_x}{F_z} = -\frac{2 \sin y + 2y \cos x + 2yz}{2xy} = -\frac{2(\sin y + y \cos x + yz)}{2xy} \\ &= -\frac{\sin y + y \cos x + yz}{xy} = \frac{-\sin y - y \cos x - yz}{xy} \\ \frac{\partial z}{\partial y} &= -\frac{F_y}{F_z} = -\frac{2x \cos y + 2 \sin x + 2xz}{2xy} = -\frac{2(x \cos y + \sin x + xz)}{2xy} \\ &= -\frac{x \cos y + \sin x + xz}{xy} = \frac{-x \cos y - \sin x - xz}{xy} \end{aligned}$$

$$\boxed{\frac{\partial z}{\partial x} = \frac{-\sin y - y \cos x - yz}{xy}}$$

$$\boxed{\frac{\partial z}{\partial y} = \frac{-x \cos y - \sin x - xz}{xy}}$$

58. We write the given function $z = uf(u^2 + v^2)$ as a function of two variables, u and w , by making the substitution $w = u^2 + v^2$. This yields $z = uf(w)$. (Note that f is now a function of one variable.) We compute $\frac{\partial z}{\partial u}$ and $\frac{\partial z}{\partial v}$ using Chain Rule II:

$$\begin{aligned} \frac{\partial z}{\partial u} &= \frac{\partial z}{\partial u} + \frac{\partial z}{\partial w} \frac{\partial w}{\partial u} \\ &= f(w) + \left(u \frac{df}{dw}\right)(2u) \end{aligned}$$

and

$$\begin{aligned} \frac{\partial z}{\partial v} &= \frac{\partial z}{\partial w} \frac{\partial w}{\partial v} \\ &= \left(u \frac{df}{dw}\right)(2v) \end{aligned}$$

then

$$2v \frac{\partial z}{\partial u} - 2u \frac{\partial z}{\partial v} = 2v \left[f(w) + \left(u \frac{df}{dw}\right)(2u) \right] - 2u \left[\left(u \frac{df}{dw}\right)(2v) \right]$$

$$\begin{aligned}
&= 2vf(w) + 4u^2v \frac{df}{dw} - 4u^2v \frac{df}{dw} \\
&= 2vf(w)
\end{aligned}$$

Multiplying top and bottom by u yields $\frac{2vuf(w)}{u} = \frac{2vz}{u}$. ✓

Note that this holds for $u \neq 0$. But, if $u = 0$, then z and all its partials are also 0, so the equation holds as well.

Chapter 13

Directional Derivatives, Gradients, and Extrema

13.1 Directional Derivatives; Gradients

Concepts and Vocabulary

1. **True**.
2. **True**.
3. **False**. The directional derivative is the dot product of two vectors so it is a **scalar**.
4. **True**.
5. **False**. The gradient of f is $f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = \sin y\mathbf{i} + x \cos y\mathbf{j}$.
6. The directional derivative $D_{\mathbf{u}}f(x_0, y_0)$ of f at (x_0, y_0) is a maximum when $\mathbf{u} = \frac{\nabla f(x_0, y_0)}{\|\nabla f(x_0, y_0)\|}$.
7. The value of $z = f(x, y)$ at (x_0, y_0) decreases most rapidly in the direction of $-\nabla f(x_0, y_0)$.
8. For a differentiable function $z = f(x, y)$, the maximum value of $D_{\mathbf{u}}f(x_0, y_0)$ is $\|\nabla f(x_0, y_0)\|$.

Skill Building

9. (a) The partial derivatives are

$$f_x(x, y) = y^2 + 2x \quad \text{and} \quad f_y(x, y) = 2xy$$

and are continuous, so f is differentiable. Using the unit vector $\mathbf{u} = \frac{1}{2}\mathbf{i} + \frac{\sqrt{3}}{2}\mathbf{j} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= (y^2 + 2x) \cdot \frac{1}{2} + (2xy) \cdot \frac{\sqrt{3}}{2} \\ &= \frac{1}{2}y^2 + x + xy\sqrt{3}. \end{aligned}$$

$$\text{Then } D_{\mathbf{u}}f(-1, 2) = \frac{1}{2}(2)^2 + (-1) + (-1)(2)\sqrt{3} = 1 - 2\sqrt{3}.$$

(b) At the point $(-1, 2)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(-1, 2) = 1 - 2\sqrt{3}$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x, y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(-1, 2, 0)$ in the direction $\mathbf{u}$ is $1 - 2\sqrt{3}$.

10. (a) The partial derivatives are

$$f_x(x, y) = 3y \quad \text{and} \quad f_y(x, y) = 3x + 2y$$

and are continuous, so f is differentiable. Using the unit vector $\mathbf{u} = \frac{\sqrt{2}}{2}\mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= (3y) \cdot \frac{\sqrt{2}}{2} + (3x + 2y) \cdot \frac{\sqrt{2}}{2} \\ &= \frac{5\sqrt{2}}{2}y + \frac{3\sqrt{2}}{2}x. \end{aligned}$$

Then $D_{\mathbf{u}}f(2, 1) = \frac{5\sqrt{2}}{2}(1) + \frac{3\sqrt{2}}{2}(2) = \boxed{\frac{11\sqrt{2}}{2}}$.

(b) At the point $(2, 1)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(2, 1) = \frac{11\sqrt{2}}{2}$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x, y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(2, 1, 0)$ in the direction $\mathbf{u}$ is $\frac{11\sqrt{2}}{2}$.

11. (a) The partial derivatives are

$$f_x(x, y) = 2y \quad \text{and} \quad f_y(x, y) = 2x - 2y$$

and are continuous, so f is differentiable. Using formula (1) with $\theta = \frac{2\pi}{3}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= (2y) \cdot \cos \frac{2\pi}{3} + (2x - 2y) \cdot \sin \frac{2\pi}{3} = (2y) \cdot \left(-\frac{1}{2}\right) + (2x - 2y) \cdot \frac{\sqrt{3}}{2} \\ &= -y + x\sqrt{3} - y\sqrt{3}. \end{aligned}$$

where $\mathbf{u} = \cos \frac{2\pi}{3}\mathbf{i} + \sin \frac{2\pi}{3}\mathbf{j}$. Then $D_{\mathbf{u}}f(-1, 3) = -(3) + (-1)\sqrt{3} - (3)\sqrt{3} = \boxed{-3 - 4\sqrt{3}}$.

(b) At the point $(-1, 3)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(-1, 3) = -3 - 4\sqrt{3}$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x, y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(-1, 3, 0)$ in the direction $\mathbf{u}$ is $-3 - 4\sqrt{3}$.

12. (a) The partial derivatives are

$$f_x(x, y) = 2y + 2x \quad \text{and} \quad f_y(x, y) = 2x$$

and are continuous, so f is differentiable. Using formula (1) with $\theta = \frac{4\pi}{3}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= (2y + 2x) \cdot \cos \frac{4\pi}{3} + (2x) \cdot \sin \frac{4\pi}{3} = (2y + 2x) \cdot \left(-\frac{1}{2}\right) + (2x) \cdot \left(-\frac{\sqrt{3}}{2}\right) \\ &= -y - x - x\sqrt{3}. \end{aligned}$$

where $\mathbf{u} = \cos \frac{4\pi}{3}\mathbf{i} + \sin \frac{4\pi}{3}\mathbf{j}$. Then $D_{\mathbf{u}}f(0, 3) = -(3) - 0 - 0\sqrt{3} = \boxed{-3}$.

(b) At the point $(0, 3)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(0, 3) = -3$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x, y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(0, 3, 0)$ in the direction $\mathbf{u}$ is -3 .

13. (a) The partial derivatives are

$$f_x(x, y) = e^y + ye^x \quad \text{and} \quad f_y(x, y) = xe^y + e^x$$

and are continuous, so f is differentiable. Using formula (1) with $\theta = \frac{\pi}{6}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= (e^y + ye^x) \cdot \cos \frac{\pi}{6} + (xe^y + e^x) \cdot \sin \frac{\pi}{6} = (e^y + ye^x) \cdot \left(\frac{\sqrt{3}}{2}\right) + (xe^y + e^x) \cdot \left(\frac{1}{2}\right) \\ &= \frac{\sqrt{3}}{2}e^y + \frac{\sqrt{3}}{2}ye^x + \frac{1}{2}xe^y + \frac{1}{2}e^x. \end{aligned}$$

where $\mathbf{u} = \cos \frac{\pi}{6} \mathbf{i} + \sin \frac{\pi}{6} \mathbf{j}$. Then $D_{\mathbf{u}}f(0,0) = \boxed{\frac{1+\sqrt{3}}{2}}$.

(b) At the point $(0,0)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(0,0) = \frac{\sqrt{3}+1}{2}$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x,y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(0,0,0)$ in the direction $\mathbf{u}$ is $\frac{\sqrt{3}+1}{2}$.

14. (a) The partial derivatives are

$$f_x(x,y) = \ln y \quad \text{and} \quad f_y(x,y) = \frac{x}{y}$$

and are continuous when $y \neq 0$, so f is differentiable when $y \neq 0$. Using formula (1) with $\theta = \frac{\pi}{4}$, we have

$$D_{\mathbf{u}}f(x,y) = \ln y \cdot \cos \frac{\pi}{4} + \frac{x}{y} \cdot \sin \frac{\pi}{4} = \frac{\sqrt{2}}{2} \left(\ln y + \frac{x}{y} \right)$$

where $\mathbf{u} = \cos \frac{\pi}{4} \mathbf{i} + \sin \frac{\pi}{4} \mathbf{j}$. Then $D_{\mathbf{u}}f(5,1) = \frac{\sqrt{2}}{2} \left(\ln(1) + \frac{5}{1} \right) = \boxed{\frac{5\sqrt{2}}{2}}$.

(b) At the point $(5,1)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(5,1) = \frac{5\sqrt{2}}{2}$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x,y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(5,1,0)$ in the direction $\mathbf{u}$ is $\frac{5\sqrt{2}}{2}$.

15. (a) First we note that $\mathbf{a}$ is not a unit vector. The unit vector $\mathbf{u}$ in the direction of $\mathbf{a}$ is $\frac{\mathbf{a}}{\|\mathbf{a}\|}$. Then

$$\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{3\mathbf{i} - 4\mathbf{j}}{\sqrt{(3)^2 + (-4)^2}} = \frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j}.$$

The partial derivatives of $f(x,y) = \tan^{-1}(yx^{-1})$ are

$$f_x(x,y) = \frac{1}{1+(yx^{-1})^2} \cdot -yx^{-2} = -\frac{y}{x^2+y^2} \quad \text{and} \quad f_y(x,y) = \frac{1}{1+(yx^{-1})^2} \cdot x^{-1} = \frac{x}{x^2+y^2}$$

and are continuous when $(x,y) \neq (0,0)$, so f is differentiable when $(x,y) \neq (0,0)$. Using the unit vector $\mathbf{u} = \frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x,y) &= -\frac{y}{x^2+y^2} \cdot \frac{3}{5} + \frac{x}{x^2+y^2} \cdot -\frac{4}{5} \\ &= \frac{-3y-4x}{5(x^2+y^2)}. \end{aligned}$$

Then $D_{\mathbf{u}}f(1,1) = \frac{-3(1)-4(1)}{5((1)^2+(1)^2)} = \boxed{-\frac{7}{10}}$.

(b) At the point $(1,1)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(1,1) = -\frac{7}{10}$.

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x,y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(1,1,0)$ in the direction $\mathbf{u}$ is $-\frac{7}{10}$.

16. (a) First we note that $\mathbf{a}$ is not a unit vector. The unit vector $\mathbf{u}$ in the direction of $\mathbf{a}$ is $\frac{\mathbf{a}}{\|\mathbf{a}\|}$. Then

$$\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{5\mathbf{i} + 12\mathbf{j}}{\sqrt{(5)^2 + (12)^2}} = \frac{5}{13}\mathbf{i} + \frac{12}{13}\mathbf{j}.$$

The partial derivatives of $f(x, y) = \ln \left((x^2 + y^2)^{1/2} \right) = \frac{1}{2} \ln (x^2 + y^2)$ are

$$f_x(x, y) = \frac{1}{2} \frac{1}{x^2 + y^2} \cdot 2x = \frac{x}{x^2 + y^2} \quad \text{and} \quad f_y(x, y) = \frac{1}{2} \frac{1}{x^2 + y^2} \cdot 2y = \frac{y}{x^2 + y^2}$$

and are continuous when $(x, y) \neq (0, 0)$, so f is differentiable when $(x, y) \neq (0, 0)$. Using the unit vector $\mathbf{u} = \frac{5}{13}\mathbf{i} + \frac{12}{13}\mathbf{j} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}$, we have

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= \frac{x}{x^2 + y^2} \cdot \frac{5}{13} + \frac{y}{x^2 + y^2} \cdot \frac{12}{13} \\ &= \frac{5x + 12y}{13(x^2 + y^2)}. \end{aligned}$$

Then $D_{\mathbf{u}}f(3, 4) = \frac{5(3) + 12(4)}{13((3)^2 + (4)^2)} = \boxed{\frac{63}{325}}.$

(b) At the point $(3, 4)$, in the direction of $\mathbf{u}$, the rate of change of the function is $D_{\mathbf{u}}f(3, 4) = \frac{63}{325}.$

(c) The slope of the tangent line to the curve C that is the intersection of the surface $f(x, y)$ and the plane perpendicular to the xy -plane that contains the line through the point $(3, 4, 0)$ in the direction $\mathbf{u}$ is $\frac{63}{325}.$

17. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (y^2 + 2x)\mathbf{i} + (2xy)\mathbf{j}.$$

The gradient of f at the point $(1, 2)$ is

$$\boxed{\nabla f(1, 2) = 6\mathbf{i} + 4\mathbf{j}}.$$

(b) The unit vector from $(1, 2)$ to $(2, 4)$ is

$$\mathbf{u} = \frac{(2-1)\mathbf{i} + (4-2)\mathbf{j}}{\sqrt{(2-1)^2 + (4-2)^2}} = \frac{1}{\sqrt{5}}\mathbf{i} + \frac{2}{\sqrt{5}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}f(1, 2)$, we have

$$D_{\mathbf{u}}f(1, 2) = \nabla f(1, 2) \cdot \mathbf{u} = (6\mathbf{i} + 4\mathbf{j}) \cdot \left(\frac{1}{\sqrt{5}}\mathbf{i} + \frac{2}{\sqrt{5}}\mathbf{j} \right) = \boxed{\frac{14\sqrt{5}}{5}}.$$

18. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (2y + 2x)\mathbf{i} + (2x)\mathbf{j}.$$

The gradient of f at the point $(-1, 1)$ is

$$\boxed{\nabla f(-1, 1) = -2\mathbf{j}}.$$

(b) The unit vector from $(-1, 1)$ to $(1, 2)$ is

$$\mathbf{u} = \frac{(1 - (-1))\mathbf{i} + (2 - 1)\mathbf{j}}{\sqrt{(1 - (-1))^2 + (2 - 1)^2}} = \frac{2}{\sqrt{5}}\mathbf{i} + \frac{1}{\sqrt{5}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}f(-1, 1)$, we have

$$D_{\mathbf{u}}f(-1, 1) = \nabla f(-1, 1) \cdot \mathbf{u} = (-2\mathbf{j}) \cdot \left(\frac{2}{\sqrt{5}}\mathbf{i} + \frac{1}{\sqrt{5}}\mathbf{j} \right) = \boxed{-\frac{2\sqrt{5}}{5}}.$$

19. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (2y + 2x)\mathbf{i} + (2x)\mathbf{j}.$$

The gradient of f at the point $(0, 3)$ is

$$\boxed{\nabla f(0, 3) = 6\mathbf{i}}.$$

(b) The unit vector from $(0, 3)$ to $(4, 1)$ is

$$\mathbf{u} = \frac{(4-0)\mathbf{i} + (1-3)\mathbf{j}}{\sqrt{(4-0)^2 + (1-3)^2}} = \frac{2}{\sqrt{5}}\mathbf{i} - \frac{1}{\sqrt{5}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}(0, 3)$, we have

$$D_{\mathbf{u}}(0, 3) = \nabla f(0, 3) \cdot \mathbf{u} = (6\mathbf{i}) \cdot \left(\frac{2}{\sqrt{5}}\mathbf{i} - \frac{1}{\sqrt{5}}\mathbf{j} \right) = \boxed{\frac{12\sqrt{5}}{5}}.$$

20. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (3y)\mathbf{i} + (3x + 2y)\mathbf{j}.$$

The gradient of f at the point $(2, 1)$ is

$$\boxed{\nabla f(2, 1) = 3\mathbf{i} + 8\mathbf{j}}.$$

(b) The unit vector from $(2, 1)$ to $(4, 1)$ is

$$\mathbf{u} = \frac{(4-2)\mathbf{i} + (1-1)\mathbf{j}}{\sqrt{(4-2)^2 + (1-1)^2}} = \mathbf{i}.$$

Using formula (3) to find $D_{\mathbf{u}}(2, 1)$, we have

$$D_{\mathbf{u}}(2, 1) = \nabla f(2, 1) \cdot \mathbf{u} = (3\mathbf{i} + 8\mathbf{j}) \cdot (\mathbf{i}) = \boxed{3}.$$

21. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (y + \cos x)\mathbf{i} + (x)\mathbf{j}.$$

The gradient of f at the point $(0, 1)$ is

$$\boxed{\nabla f(0, 1) = 2\mathbf{i}}.$$

(b) The unit vector from $(0, 1)$ to $(\pi, 2)$ is

$$\mathbf{u} = \frac{(\pi-0)\mathbf{i} + (2-1)\mathbf{j}}{\sqrt{(\pi-0)^2 + (2-1)^2}} = \frac{\pi}{\sqrt{\pi^2 + 1}}\mathbf{i} + \frac{1}{\sqrt{\pi^2 + 1}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}(0, 1)$, we have

$$D_{\mathbf{u}}(0, 1) = \nabla f(0, 1) \cdot \mathbf{u} = (2\mathbf{i}) \cdot \left(\frac{\pi}{\sqrt{\pi^2 + 1}}\mathbf{i} + \frac{1}{\sqrt{\pi^2 + 1}}\mathbf{j} \right) = \boxed{\frac{2\pi}{\sqrt{\pi^2 + 1}}}.$$

22. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = ye^{xy}\mathbf{i} + (xe^{xy} + \cos y)\mathbf{j}.$$

The gradient of f at the point $\left(0, \frac{\pi}{2}\right)$ is

$$\nabla f\left(0, \frac{\pi}{2}\right) = \frac{\pi}{2} \mathbf{i}.$$

(b) The unit vector from $\left(0, \frac{\pi}{2}\right)$ to $(1, 0)$ is

$$\mathbf{u} = \frac{(1-0)\mathbf{i} + \left(0 - \frac{\pi}{2}\right)\mathbf{j}}{\sqrt{(1-0)^2 + \left(0 - \frac{\pi}{2}\right)^2}} = \frac{2}{\sqrt{\pi^2 + 4}}\mathbf{i} - \frac{\pi}{\sqrt{\pi^2 + 4}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}\left(0, \frac{\pi}{2}\right)$, we have

$$D_{\mathbf{u}}\left(0, \frac{\pi}{2}\right) = \nabla f\left(0, \frac{\pi}{2}\right) \cdot \mathbf{u} = \left(\frac{\pi}{2}\mathbf{i}\right) \cdot \left(\frac{2}{\sqrt{\pi^2 + 4}}\mathbf{i} - \frac{\pi}{\sqrt{\pi^2 + 4}}\mathbf{j}\right) = \boxed{\frac{\pi}{\sqrt{\pi^2 + 4}}}.$$

23. (a) The partial derivatives were computed in Problem 15, so the gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = \left(-\frac{y}{x^2 + y^2}\right)\mathbf{i} + \left(\frac{x}{x^2 + y^2}\right)\mathbf{j}.$$

The gradient of f at the point $(1, 0)$ is

$$\nabla f(1, 0) = \mathbf{j}.$$

(b) The unit vector from $(1, 0)$ to $(4, \pi)$ is

$$\mathbf{u} = \frac{(4-1)\mathbf{i} + (\pi-0)\mathbf{j}}{\sqrt{(4-1)^2 + (\pi-0)^2}} = \frac{3}{\sqrt{\pi^2 + 9}}\mathbf{i} + \frac{\pi}{\sqrt{\pi^2 + 9}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}(1, 0)$, we have

$$D_{\mathbf{u}}(1, 0) = \nabla f(1, 0) \cdot \mathbf{u} = (\mathbf{j}) \cdot \left(\frac{3}{\sqrt{\pi^2 + 9}}\mathbf{i} + \frac{\pi}{\sqrt{\pi^2 + 9}}\mathbf{j}\right) = \boxed{\frac{\pi}{\sqrt{\pi^2 + 9}}}.$$

24. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = \left(\frac{x}{x^2 + y^2}\right)\mathbf{i} + \left(\frac{y}{x^2 + y^2}\right)\mathbf{j}.$$

The gradient of f at the point $(3, 4)$ is

$$\nabla f(3, 4) = \frac{3}{25}\mathbf{i} + \frac{4}{25}\mathbf{j}.$$

(b) The unit vector from $(3, 4)$ to $(0, 5)$ is

$$\mathbf{u} = \frac{(0-3)\mathbf{i} + (5-4)\mathbf{j}}{\sqrt{(0-3)^2 + (5-4)^2}} = -\frac{3}{\sqrt{10}}\mathbf{i} + \frac{1}{\sqrt{10}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}(3, 4)$, we have

$$D_{\mathbf{u}}(3, 4) = \nabla f(3, 4) \cdot \mathbf{u} = \left(\frac{3}{25}\mathbf{i} + \frac{4}{25}\mathbf{j}\right) \cdot \left(-\frac{3}{\sqrt{10}}\mathbf{i} + \frac{1}{\sqrt{10}}\mathbf{j}\right) = \boxed{-\frac{1}{5\sqrt{10}}}.$$

25. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (2xe^y)\mathbf{i} + (x^2e^y)\mathbf{j}.$$

The gradient of f at the point $(2, 0)$ is

$$\boxed{\nabla f(2, 0) = 4\mathbf{i} + 4\mathbf{j}}.$$

(b) The unit vector from $(2, 0)$ to $(3, 0)$ is

$$\mathbf{u} = \frac{(3-2)\mathbf{i} + (0-0)\mathbf{j}}{\sqrt{(3-2)^2 + (0-0)^2}} = \mathbf{i}.$$

Using formula (3) to find $D_{\mathbf{u}}(2, 0)$, we have

$$D_{\mathbf{u}}(2, 0) = \nabla f(2, 0) \cdot \mathbf{u} = (4\mathbf{i} + 4\mathbf{j}) \cdot (\mathbf{i}) = \boxed{4}.$$

26. (a) The gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = (2xe^{x^2+y^2})\mathbf{i} + (2ye^{x^2+y^2})\mathbf{j}.$$

The gradient of f at the point $(1, 2)$ is

$$\boxed{\nabla f(1, 2) = 2e^5\mathbf{i} + 4e^5\mathbf{j}}.$$

(b) The unit vector from $(1, 2)$ to $(2, 3)$ is

$$\mathbf{u} = \frac{(2-1)\mathbf{i} + (3-2)\mathbf{j}}{\sqrt{(2-1)^2 + (3-2)^2}} = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}.$$

Using formula (3) to find $D_{\mathbf{u}}(1, 2)$, we have

$$D_{\mathbf{u}}(1, 2) = \nabla f(1, 2) \cdot \mathbf{u} = (2e^5\mathbf{i} + 4e^5\mathbf{j}) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}\right) = \boxed{2\sqrt{2}e^5}.$$

27. (a) The gradient of f at (x, y, z) is

$$\nabla f(x, y, z) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = (2xy - yz^2)\mathbf{i} + (x^2 - xz^2)\mathbf{j} + (-2xyz)\mathbf{k}.$$

The gradient of f at the point $(0, 1, 2)$ is

$$\boxed{\nabla f(0, 1, 2) = -4\mathbf{i} + 0\mathbf{j} + 0\mathbf{k} = -4\mathbf{i}}.$$

(b) The unit vector from $(0, 1, 2)$ to $(1, 4, 3)$ is

$$\mathbf{u} = \frac{(1-0)\mathbf{i} + (4-1)\mathbf{j} + (3-2)\mathbf{k}}{\sqrt{(1-0)^2 + (4-1)^2 + (3-2)^2}} = \frac{1}{\sqrt{11}}\mathbf{i} + \frac{3}{\sqrt{11}}\mathbf{j} + \frac{1}{\sqrt{11}}\mathbf{k}.$$

Using the formula for the directional derivative at the end of the section to find $D_{\mathbf{u}}(0, 1, 2)$, we have

$$D_{\mathbf{u}}(0, 1, 2) = \nabla f(0, 1, 2) \cdot \mathbf{u} = (-4\mathbf{i}) \cdot \left(\frac{1}{\sqrt{11}}\mathbf{i} + \frac{3}{\sqrt{11}}\mathbf{j} + \frac{1}{\sqrt{11}}\mathbf{k}\right) = \boxed{-\frac{4\sqrt{11}}{11}}.$$

28. (a) The gradient of f at (x, y, z) is

$$\nabla f(x, y, z) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = (2xy + z^2)\mathbf{i} + (x^2 + 2yz)\mathbf{j} + (y^2 + 2zx)\mathbf{k}.$$

The gradient of f at the point $(1, 2, -1)$ is

$$\nabla f(1, 2, -1) = 5\mathbf{i} + -3\mathbf{j} + 2\mathbf{k}.$$

(b) The unit vector from $(1, 2, -1)$ to $(2, 0, 1)$ is

$$\mathbf{u} = \frac{(2-1)\mathbf{i} + (0-2)\mathbf{j} + (1-(-1))\mathbf{k}}{\sqrt{(2-1)^2 + (0-2)^2 + (1-(-1))^2}} = \frac{1}{3}\mathbf{i} - \frac{2}{3}\mathbf{j} + \frac{2}{3}\mathbf{k}.$$

Using the formula for the directional derivative at the end of the section to find $D_{\mathbf{u}}(1, 2, -1)$, we have

$$D_{\mathbf{u}}(1, 2, -1) = \nabla f(1, 2, -1) \cdot \mathbf{u} = (5\mathbf{i} + -3\mathbf{j} + 2\mathbf{k}) \cdot \left(\frac{1}{3}\mathbf{i} - \frac{2}{3}\mathbf{j} + \frac{2}{3}\mathbf{k}\right) = \boxed{5}.$$

29. (a) The partial derivatives of $f(x, y, z) = z \tan^{-1}(yx^{-1})$ are

$$\begin{aligned} f_x(x, y, z) &= z \cdot \frac{1}{1 + (yx^{-1})^2} \cdot (-x^{-2}) = -\frac{zy}{x^2 + y^2} \\ f_y(x, y, z) &= z \cdot \frac{1}{1 + (yx^{-1})^2} \cdot x^{-1} = \frac{zx}{x^2 + y^2} \\ f_z(x, y, z) &= \tan^{-1} \frac{y}{x}. \end{aligned}$$

The gradient of f at (x, y, z) is

$$\nabla f(x, y) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = \left(-\frac{zy}{x^2 + y^2}\right)\mathbf{i} + \left(\frac{zx}{x^2 + y^2}\right)\mathbf{j} + \left(\tan^{-1} \frac{y}{x}\right)\mathbf{k}.$$

The gradient of f at the point $(1, 1, 3)$ is

$$\nabla f(1, 1, 3) = -\frac{3}{2}\mathbf{i} + \frac{3}{2}\mathbf{j} + \frac{\pi}{4}\mathbf{k}.$$

(b) The unit vector from $(1, 1, 3)$ to $(2, 0, -2)$ is

$$\mathbf{u} = \frac{(2-1)\mathbf{i} + (0-1)\mathbf{j} + (-2-3)\mathbf{k}}{\sqrt{(2-1)^2 + (0-1)^2 + (-2-3)^2}} = \frac{1}{3\sqrt{3}}\mathbf{i} - \frac{1}{3\sqrt{3}}\mathbf{j} - \frac{5}{3\sqrt{3}}\mathbf{k}.$$

Using the formula for the directional derivative at the end of the section to find $D_{\mathbf{u}}(1, 1, 3)$, we have

$$D_{\mathbf{u}}(1, 1, 3) = \nabla f(1, 1, 3) \cdot \mathbf{u} = \left(-\frac{3}{2}\mathbf{i} + \frac{3}{2}\mathbf{j} + \frac{\pi}{4}\mathbf{k}\right) \cdot \left(\frac{1}{3\sqrt{3}}\mathbf{i} - \frac{1}{3\sqrt{3}}\mathbf{j} - \frac{5}{3\sqrt{3}}\mathbf{k}\right) = -\frac{1}{\sqrt{3}} - \frac{5\pi}{12\sqrt{3}} = \boxed{-\frac{(12 + 5\pi)\sqrt{3}}{36}}.$$

30. (a) The gradient of f at (x, y, z) is

$$\nabla f(x, y) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = (\cos x \cos(y + z))\mathbf{i} + (-\sin x \sin(y + z))\mathbf{j} + (-\sin x \sin(y + z))\mathbf{k}.$$

The gradient of f at the point $(1, 1, 1)$ is

$$\nabla f(1, 1, 1) = \cos(1) \cos(2)\mathbf{i} - \sin(1) \sin(2)\mathbf{j} - \sin(1) \sin(2)\mathbf{j}.$$

(b) The unit vector from $(1, 1, 1)$ to $(2, -1, 0)$ is

$$\mathbf{u} = \frac{(2-1)\mathbf{i} + (-1-1)\mathbf{j} + (0-1)\mathbf{k}}{\sqrt{(2-1)^2 + (-1-1)^2 + (0-1)^2}} = \frac{1}{\sqrt{6}}\mathbf{i} - \frac{2}{\sqrt{6}}\mathbf{j} - \frac{1}{\sqrt{6}}\mathbf{k}.$$

Using the formula for the directional derivative at the end of the section to find $D_{\mathbf{u}}(1, 1, 1)$, we have

$$\begin{aligned} D_{\mathbf{u}}(1, 1, 1) &= \nabla f(1, 1, 1) \cdot \mathbf{u} = (\cos(1) \cos(2) \mathbf{i} - \sin(1) \sin(2) \mathbf{j} - \sin(1) \sin(2) \mathbf{j}) \cdot \left(\frac{1}{\sqrt{6}} \mathbf{i} - \frac{2}{\sqrt{6}} \mathbf{j} - \frac{1}{\sqrt{6}} \mathbf{k} \right) \\ &= \boxed{\frac{\cos(1) \cos(2)}{\sqrt{6}} + \frac{3 \sin(1) \sin(2)}{\sqrt{6}}}. \end{aligned}$$

31. (a) The gradient of f at (x, y, z) is

$$\nabla f(x, y) = f_x(x, y, z) \mathbf{i} + f_y(x, y, z) \mathbf{j} + f_z(x, y, z) \mathbf{k} = \left(\frac{x}{\sqrt{x^2 + y^2 + z^2}} \right) \mathbf{i} + \left(\frac{y}{\sqrt{x^2 + y^2 + z^2}} \right) \mathbf{j} + \left(\frac{z}{\sqrt{x^2 + y^2 + z^2}} \right) \mathbf{k}.$$

The gradient of f at the point $(3, 4, 0)$ is

$$\boxed{\nabla f(3, 4, 0) = \frac{3}{5} \mathbf{i} + \frac{4}{5} \mathbf{j}}.$$

(b) The unit vector from $(3, 4, 0)$ to $(1, -1, 1)$ is

$$\mathbf{u} = \frac{(1-3) \mathbf{i} + (-1-4) \mathbf{j} + (1-0) \mathbf{k}}{\sqrt{(1-3)^2 + (-1-4)^2 + (1-0)^2}} = -\frac{2}{\sqrt{30}} \mathbf{i} - \frac{5}{\sqrt{30}} \mathbf{j} + \frac{1}{\sqrt{30}} \mathbf{k}.$$

Using the formula for the directional derivative at the end of the section to find $D_{\mathbf{u}}(3, 4, 0)$, we have

$$D_{\mathbf{u}}(3, 4, 0) = \nabla f(3, 4, 0) \cdot \mathbf{u} = \left(\frac{3}{5} \mathbf{i} + \frac{4}{5} \mathbf{j} \right) \cdot \left(-\frac{2}{\sqrt{30}} \mathbf{i} - \frac{5}{\sqrt{30}} \mathbf{j} + \frac{1}{\sqrt{30}} \mathbf{k} \right) = -\frac{26}{5\sqrt{30}} = \boxed{-\frac{13\sqrt{30}}{75}}.$$

32. (a) The partial derivatives of $f(x, y, z) = x(x^2 + 2y^2 + 3z^2)^{-1/2}$ are

$$\begin{aligned} f_x(x, y, z) &= (x^2 + 2y^2 + 3z^2)^{-1/2} - \frac{1}{2} x (x^2 + 2y^2 + 3z^2)^{-3/2} \cdot 2x = \frac{2y^2 + 3z^2}{(x^2 + 2y^2 + 3z^2)^{3/2}} \\ f_y(x, y, z) &= -\frac{1}{2} x (x^2 + 2y^2 + 3z^2)^{-3/2} \cdot 4y = -\frac{2xy}{(x^2 + 2y^2 + 3z^2)^{3/2}} \\ f_z(x, y, z) &= -\frac{1}{2} x (x^2 + 2y^2 + 3z^2)^{-3/2} \cdot 6z = -\frac{3xz}{(x^2 + 2y^2 + 3z^2)^{3/2}}. \end{aligned}$$

The gradient of f at (x, y, z) is

$$\begin{aligned} \nabla f(x, y) &= f_x(x, y, z) \mathbf{i} + f_y(x, y, z) \mathbf{j} + f_z(x, y, z) \mathbf{k} \\ &= \left(\frac{2y^2 + 3z^2}{(x^2 + 2y^2 + 3z^2)^{3/2}} \right) \mathbf{i} + \left(-\frac{2xy}{(x^2 + 2y^2 + 3z^2)^{3/2}} \right) \mathbf{j} + \left(-\frac{3xz}{(x^2 + 2y^2 + 3z^2)^{3/2}} \right) \mathbf{k}. \end{aligned}$$

The gradient of f at the point $(1, 2, 1)$ is

$$\boxed{\nabla f(1, 2, 1) = \frac{11\sqrt{3}}{72} \mathbf{i} - \frac{\sqrt{3}}{18} \mathbf{j} - \frac{\sqrt{3}}{24} \mathbf{k}}.$$

(b) The unit vector from $(1, 2, 1)$ to $(-1, 1, 1)$ is

$$\mathbf{u} = \frac{(-1-1) \mathbf{i} + (1-2) \mathbf{j} + (1-1) \mathbf{k}}{\sqrt{(-1-1)^2 + (1-2)^2 + (1-1)^2}} = -\frac{2}{\sqrt{5}} \mathbf{i} - \frac{1}{\sqrt{5}} \mathbf{j}.$$

Using the formula for the directional derivative at the end of the section to find $D_{\mathbf{u}}(1, 2, 1)$, we have

$$D_{\mathbf{u}}(1, 2, 1) = \nabla f(1, 2, 1) \cdot \mathbf{u} = \left(\frac{11\sqrt{3}}{72}\mathbf{i} - \frac{\sqrt{3}}{18}\mathbf{j} - \frac{\sqrt{3}}{24}\mathbf{k} \right) \cdot \left(-\frac{2}{\sqrt{5}}\mathbf{i} - \frac{1}{\sqrt{5}}\mathbf{j} \right) = \boxed{-\frac{\sqrt{15}}{20}}.$$

33. (a) We begin by finding the gradient of f at $(-1, 2)$.

$$\begin{aligned}\nabla f(x, y) &= (y^2 + 2x)\mathbf{i} + 2xy\mathbf{j} \\ \nabla f(-1, 2) &= 2\mathbf{i} - 4\mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(-1, 2)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\mathbf{u} = \frac{\sqrt{5}}{5}\mathbf{i} - \frac{2\sqrt{5}}{5}\mathbf{j}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(-1, 2)\| = \sqrt{4 + 16} = \boxed{2\sqrt{5}}.$$

34. (a) We begin by finding the gradient of f at $(2, 1)$.

$$\begin{aligned}\nabla f(x, y) &= 3y\mathbf{i} + (3x + 2y)\mathbf{j} \\ \nabla f(2, 1) &= 3\mathbf{i} + 8\mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(2, 1)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\mathbf{u} = \frac{3\sqrt{73}}{73}\mathbf{i} + \frac{8\sqrt{73}}{73}\mathbf{j}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(2, 1)\| = \sqrt{9 + 64} = \boxed{\sqrt{73}}.$$

35. (a) We begin by finding the gradient of f at $(0, 0)$.

$$\begin{aligned}\nabla f(x, y) &= (e^y + ye^x)\mathbf{i} + (xe^y + e^x)\mathbf{j} \\ \nabla f(0, 0) &= \mathbf{i} + \mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(0, 0)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\mathbf{u} = \frac{\sqrt{2}}{2}\mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(0, 0)\| = \sqrt{1 + 1} = \boxed{\sqrt{2}}.$$

36. (a) We begin by finding the gradient of f at $(5, 1)$.

$$\begin{aligned}\nabla f(x, y) &= \ln y\mathbf{i} + \frac{x}{y}\mathbf{j} \\ \nabla f(5, 1) &= 5\mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(5, 1)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\boxed{\mathbf{u} = \mathbf{j}}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(5, 1)\| = \sqrt{0 + 25} = \boxed{5}.$$

37. (a) We begin by finding the gradient of f at $(1, 2)$.

$$\begin{aligned}\nabla f(x, y) &= \frac{-x^2 + y^2}{(x^2 + y^2)^2} \mathbf{i} + \frac{-2xy}{(x^2 + y^2)^2} \mathbf{j} \\ \nabla f(1, 2) &= \frac{3}{25} \mathbf{i} - \frac{4}{25} \mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(1, 2)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\boxed{\mathbf{u} = \frac{3}{5} \mathbf{i} - \frac{4}{5} \mathbf{j}}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(1, 2)\| = \sqrt{\frac{9}{625} + \frac{16}{625}} = \boxed{\frac{1}{5}}.$$

38. (a) We begin by finding the gradient of f at $(3, 4)$.

$$\begin{aligned}\nabla f(x, y) &= \frac{x}{\sqrt{x^2 + y^2}} \mathbf{i} + \frac{y}{\sqrt{x^2 + y^2}} \mathbf{j} \\ \nabla f(3, 4) &= \frac{3}{5} \mathbf{i} + \frac{4}{5} \mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(3, 4)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\boxed{\mathbf{u} = \frac{3}{5} \mathbf{i} + \frac{4}{5} \mathbf{j}}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(3, 4)\| = \sqrt{\frac{9}{25} + \frac{16}{25}} = \boxed{1}.$$

39. (a) The partial derivatives of f were computed in Problem 29 above. We begin by finding the gradient of f at $(1, 1, 3)$.

$$\begin{aligned}\nabla f(x, y, z) &= \left(-\frac{zy}{x^2 + y^2} \right) \mathbf{i} + \left(\frac{zx}{x^2 + y^2} \right) \mathbf{j} + \left(\tan^{-1} \frac{y}{x} \right) \mathbf{k} \\ \nabla f(1, 1, 3) &= -\frac{3}{2} \mathbf{i} + \frac{3}{2} \mathbf{j} + \frac{\pi}{4} \mathbf{k}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(1, 1, 3)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\boxed{\mathbf{u} = -\frac{6}{\sqrt{72 + \pi^2}} \mathbf{i} + \frac{6}{\sqrt{72 + \pi^2}} \mathbf{j} + \frac{\pi}{\sqrt{72 + \pi^2}} \mathbf{k}}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(1, 1, 3)\| = \sqrt{\frac{9}{4} + \frac{9}{4} + \frac{\pi^2}{16}} = \sqrt{\frac{9}{2} + \frac{\pi^2}{16}}.$$

40. (a) We begin by finding the gradient of f at $(3, 4, 0)$.

$$\begin{aligned}\nabla f(x, y, z) &= \left(\frac{x}{\sqrt{x^2 + y^2 + z^2}} \right) \mathbf{i} + \left(\frac{y}{\sqrt{x^2 + y^2 + z^2}} \right) \mathbf{j} + \left(\frac{z}{\sqrt{x^2 + y^2 + z^2}} \right) \mathbf{k} \\ \nabla f(3, 4, 0) &= \frac{3}{5} \mathbf{i} + \frac{4}{5} \mathbf{j}\end{aligned}$$

The direction $\mathbf{u}$ for which $D_{\mathbf{u}}f(3, 4, 0)$ is maximum occurs when ∇f and $\mathbf{u}$ have the same direction. That is, the directional derivative is maximized in the direction

$$\mathbf{u} = \frac{3}{5} \mathbf{i} + \frac{4}{5} \mathbf{j}.$$

(b) The maximum value of the directional derivative equals the magnitude of the gradient, namely

$$\|\nabla f(3, 4, 0)\| = \sqrt{\frac{9}{25} + \frac{16}{25}} = \boxed{1}.$$

41. Because $f(3, 4) = 3^2 + 4^2 = 25$, the point P is on the level curve $x^2 + y^2 = 25$. Since

$$\nabla f(x, y) = 2x\mathbf{i} + 2y\mathbf{j}$$

the gradient at P is

$$\nabla f(3, 4) = 6\mathbf{i} + 8\mathbf{j}.$$

42. Because $f(2, -1) = 2^2 - (-1)^2 = 3$, the point P is on the level curve $x^2 - y^2 = 3$. Since

$$\nabla f(x, y) = 2x\mathbf{i} - 2y\mathbf{j}$$

the gradient at P is

$$\nabla f(2, -1) = 4\mathbf{i} + 2\mathbf{j}.$$

43. Because $f\left(3, \frac{\sqrt{5}}{2}\right) = 3^2 - 4\left(\frac{\sqrt{5}}{2}\right)^2 = 4$, the point P is on the level curve $x^2 - 4y^2 = 4$. Since

$$\nabla f(x, y) = 2x\mathbf{i} - 8y\mathbf{j}$$

the gradient at P is

$$\nabla f\left(3, \frac{\sqrt{5}}{2}\right) = 6\mathbf{i} - 4\sqrt{5}\mathbf{j}.$$

44. Because $f(-2, 0) = (-2)^2 + 4(0)^2 = 4$, the point P is on the level curve $x^2 + 4y^2 = 4$. Since

$$\nabla f(x, y) = 2x\mathbf{i} + 8y\mathbf{j}$$

the gradient at P is

$$\nabla f(-2, 0) = -4\mathbf{i}.$$

45. Because $f\left(3, \frac{1}{9}\right) = 3^2 \cdot \frac{1}{9} = 1$, the point P is on the level curve $x^2y = 1$. Since

$$\nabla f(x, y) = 2xy\mathbf{i} + x^2\mathbf{j}$$

the gradient at P is

$$\nabla f\left(3, \frac{1}{9}\right) = \frac{2}{3}\mathbf{i} + 9\mathbf{j}.$$

46. Because $f(1, 1) = 1 \cdot 1 = 1$, the point P is on the level curve $xy = 1$. Since

$$\nabla f(x, y) = y\mathbf{i} + x\mathbf{j}$$

the gradient at P is

$$\nabla f(1, 1) = \mathbf{i} + \mathbf{j}.$$

Applications and Extensions

47. (a) The rate of change in temperature at $(0, 0)$ is $D_{\mathbf{u}}T(0, 0)$ where $\mathbf{u}$ is the unit vector in the direction of $3\mathbf{i} - 4\mathbf{j}$. That is, $\mathbf{u} = \frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j}$. To compute the directional derivative, we first compute the gradient of T .

$$\begin{aligned} T_x(x, y) &= e^x(\sin x + \sin y) + e^x(\cos x) \\ T_y(x, y) &= e^x \cos y, \end{aligned}$$

so

$$\nabla T(x, y) = (e^x(\sin x + \sin y) + e^x(\cos x))\mathbf{i} + e^x \cos y\mathbf{j}.$$

Then

$$D_{\mathbf{u}}T(0, 0) = \nabla T(0, 0) \cdot \mathbf{u} = (\mathbf{i} + \mathbf{j}) \cdot \left(\frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j}\right) = -\frac{1}{5}.$$

The rate of change in temperature at $(0, 0)$ in the direction of $3\mathbf{i} - 4\mathbf{j}$ is $\boxed{-\frac{1}{5}^\circ\text{C}}$.

(b) The greatest temperature increase at $(0, 0)$ occurs in the direction of the gradient at $(0, 0)$, namely

$$\nabla T(0, 0) = \mathbf{i} + \mathbf{j}.$$

The unit vector in this direction is

$$\mathbf{u} = \frac{\sqrt{2}}{2}\mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j}.$$

(c) The greatest temperature decrease at $(0, 0)$ occurs in the opposite direction of the gradient at $(0, 0)$, namely

$$-\nabla T(0, 0) = -\mathbf{i} - \mathbf{j}.$$

The unit vector in this direction is

$$\mathbf{u} = -\frac{\sqrt{2}}{2}\mathbf{i} - \frac{\sqrt{2}}{2}\mathbf{j}.$$

(d) The rate of change in T at $(0, 0)$ remains the same for directions orthogonal to the gradient $\nabla T(0, 0) = \mathbf{i} + \mathbf{j}$. Those two directions are $\boxed{\pm(\mathbf{i} - \mathbf{j})}$.

48. (a) The vector from (x, y) to $(0, 0)$ is $\mathbf{v} = -x\mathbf{i} - y\mathbf{j}$ and the unit vector in this same direction is $\mathbf{u} = -\frac{x}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{y}{\sqrt{x^2 + y^2}}\mathbf{j}$. The rate of change of V in the direction of $\mathbf{u}$, namely $D_{\mathbf{u}}V(x, y)$ is

$$\begin{aligned} D_{\mathbf{u}}V(x, y) &= \nabla V(x, y) \cdot \mathbf{u} = \left(\frac{x}{x^2 + y^2}\mathbf{i} + \frac{y}{x^2 + y^2}\mathbf{j} \right) \cdot \left(-\frac{x}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{y}{\sqrt{x^2 + y^2}}\mathbf{j} \right) \\ &= -\frac{x^2 + y^2}{(x^2 + y^2)^{3/2}} = \boxed{-\frac{1}{\sqrt{x^2 + y^2}}}, \end{aligned}$$

where the partial derivatives were computed in Problem 16 above.

(b) The two unit vectors orthogonal to the direction in part (a) are $\pm \left(\frac{y}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{x}{\sqrt{x^2 + y^2}}\mathbf{j} \right)$. We will label them $\mathbf{u}_1 = \frac{y}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{x}{\sqrt{x^2 + y^2}}\mathbf{j}$ and $\mathbf{u}_2 = -\frac{y}{\sqrt{x^2 + y^2}}\mathbf{i} + \frac{x}{\sqrt{x^2 + y^2}}\mathbf{j}$. Then the rate of change of V in the direction of $\mathbf{u}_1$ and $\mathbf{u}_2$, respectively, are

$$\begin{aligned} D_{\mathbf{u}_1}V(x, y) &= \nabla V(x, y) \cdot \mathbf{u}_1 = \left(\frac{x}{x^2 + y^2}\mathbf{i} + \frac{y}{x^2 + y^2}\mathbf{j} \right) \cdot \left(\frac{y}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{x}{\sqrt{x^2 + y^2}}\mathbf{j} \right) = \boxed{0} \\ D_{\mathbf{u}_2}V(x, y) &= \nabla V(x, y) \cdot \mathbf{u}_2 = \left(\frac{x}{x^2 + y^2}\mathbf{i} + \frac{y}{x^2 + y^2}\mathbf{j} \right) \cdot \left(-\frac{y}{\sqrt{x^2 + y^2}}\mathbf{i} + \frac{x}{\sqrt{x^2 + y^2}}\mathbf{j} \right) = \boxed{0} \end{aligned}$$

(c) The greatest increase in potential V occurs in the direction of the gradient, namely

$$\boxed{\nabla V(x, y) = \frac{x}{x^2 + y^2}\mathbf{i} + \frac{y}{x^2 + y^2}\mathbf{j}}.$$

(d) The greatest decrease in potential V occurs in the opposite direction of the gradient, namely

$$\boxed{-\nabla V(x, y) = -\frac{x}{x^2 + y^2}\mathbf{i} - \frac{y}{x^2 + y^2}\mathbf{j}}.$$

49. The water will flow in the direction of maximum decrease from the point $(1, 2, 2)$. The direction of maximum decrease occurs in the opposite direction of the gradient of z at the point $(1, 2, 2)$. The gradient of z is

$$\nabla z(x, y) = -4x\mathbf{i} - 2y\mathbf{j},$$

so the gradient at $(1, 2, 2)$ is $\nabla z(1, 2) = -4\mathbf{i} - 4\mathbf{j}$. This means the water will flow in the direction of $4\mathbf{i} + 4\mathbf{j}$. The unit vector in this direction is $\boxed{\frac{\sqrt{2}}{2}\mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j}}$.

50. (a) The unit vector from $(3, 4)$ to $(4, 3)$ is $\mathbf{u} = \frac{(4-3)\mathbf{i} + (3-4)\mathbf{j}}{\sqrt{(4-3)^2 + (3-4)^2}} = \frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j}$. The gradient of T is $\nabla T(x, y) = 6x\mathbf{i} + 8y\mathbf{j}$. The rate of change of the temperature is

$$\begin{aligned} D_{\mathbf{u}}T(3, 4) &= \nabla T(3, 4) \cdot \mathbf{u} = (18\mathbf{i} + 32\mathbf{j}) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j} \right) \\ &= -\frac{14}{\sqrt{2}} = -7\sqrt{2}. \end{aligned}$$

We are asked for how fast the temperature is changing, so we find the absolute value of the rate of change, which means the temperature is changing by $\boxed{7\sqrt{2}^\circ\text{C per unit of distance}}$.

(b) If we want to cool off as fast as possible, we want the temperature to decrease as quickly as possible, which is in the opposite direction of the gradient at $(4, 3)$. So we should move in the direction of

$$\boxed{-\nabla T(4, 3) = -24\mathbf{i} - 24\mathbf{j}}.$$

(c) If we want to stay at a constant temperature, we want to move along points (x, y) such that $T(x, y) = T(4, 3) = 89$. This means, we must be on the path

$$\begin{aligned} T(x, y) &= 89 \\ 3x^2 + 4y^2 + 5 &= 89 \end{aligned}$$

$$\boxed{\frac{x^2}{28} + \frac{y^2}{21} = 1}$$

to remain at a constant temperature.

(d) At the origin, the gradient is $\nabla T(0, 0) = 0\mathbf{i} + 0\mathbf{j}$ so the directional derivative, in any direction, will be 0.

51. The gradient of T is $\nabla T(x, y) = \sin(2y)\mathbf{i} + 2x \cos(2y)\mathbf{j}$. The unit vector in the direction making an angle of $\frac{\pi}{6}$ with the positive x -axis is $\mathbf{u} = \cos \frac{\pi}{6}\mathbf{i} + \sin \frac{\pi}{6}\mathbf{j} = \frac{\sqrt{3}}{2}\mathbf{i} + \frac{1}{2}\mathbf{j}$. The rate of change of the temperature at the point $\left(1, \frac{\pi}{4}\right)$ in the direction $\mathbf{u}$ is

$$\begin{aligned} D_{\mathbf{u}}T\left(1, \frac{\pi}{4}\right) &= \nabla T\left(1, \frac{\pi}{4}\right) \cdot \mathbf{u} = (\mathbf{i}) \cdot \left(\frac{\sqrt{3}}{2}\mathbf{i} + \frac{1}{2}\mathbf{j}\right) \\ &= \boxed{\frac{\sqrt{3}}{2}^\circ\text{C per unit of distance}}. \end{aligned}$$

52. This question can be rephrased to find the unit vector(s) $\mathbf{u}$ such that

$$D_{\mathbf{u}}z(-1, 1) = \nabla z(-1, 1) \cdot \mathbf{u} = 2.$$

The gradient of z is $\nabla z(x, y) = y^2\mathbf{i} + 2xy\mathbf{j}$ so $\nabla z(-1, 1) = \mathbf{i} - 2\mathbf{j}$. If we let $\mathbf{u} = a\mathbf{i} + b\mathbf{j}$, then

$$\begin{aligned} \nabla z(-1, 1) \cdot \mathbf{u} &= 2 \\ (\mathbf{i} - 2\mathbf{j}) \cdot (a\mathbf{i} + b\mathbf{j}) &= 2 \\ a - 2b &= 2. \end{aligned}$$

Recalling that $\mathbf{u}$ is a unit vector $\sqrt{a^2 + b^2} = 1$ or $a = \pm\sqrt{1 - b^2}$, we can plug each of these in to solve for a and b . First we plug in the positive square root:

$$\begin{aligned} \sqrt{1 - b^2} - 2b &= 2 \\ 1 - b^2 &= (2 + 2b)^2 \\ 1 - b^2 &= 4 + 8b + 4b^2 \\ b &= -1, -\frac{3}{5}. \end{aligned}$$

Using the equation $a - 2b = 2$, or $a = 2 + 2b$, we find that the a value corresponding to $b = -1$ is $a = 0$, and the a value corresponding to $b = -\frac{3}{5}$ is $a = \frac{4}{5}$. This leads to the two unit vectors $-\mathbf{j}$ and $\frac{4}{5}\mathbf{i} - \frac{3}{5}\mathbf{j}$. If we plug in the negative square root, we will get the same equation to solve so we will get the same unit vectors. So

if we want a rate of change of z to be 2, we move in either the direction of $\boxed{-\mathbf{j}}$ or $\boxed{\frac{4}{5}\mathbf{i} - \frac{3}{5}\mathbf{j}}$.

53. (a) The gradient of z is $\nabla z = 8x\mathbf{i} + 18y\mathbf{j}$. The maximum rate of change at $(2, 1)$ occurs in the direction of the gradient at that point, so $\nabla z(2, 1) = 16\mathbf{i} + 18\mathbf{j}$. The unit vector in this direction is $\boxed{\frac{8\sqrt{145}}{145}\mathbf{i} + \frac{9\sqrt{145}}{145}\mathbf{j}}$.

(b) To verify that this vector is normal, we will compute the direction of the tangent line and verify that the directions of the tangent line and of the gradient are normal. First we find $\frac{dy}{dx}$ using implicit differentiation.

$$\begin{aligned} 8x + 18y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{8x}{18y}. \end{aligned}$$

This means the slope of the tangent line to the curve at $(2, 1)$ is $-\frac{16}{18}$. The direction of the tangent line is then $-16\mathbf{i} + 16\mathbf{j}$. By taking the dot product of this vector and the gradient found in part (a), we will obtain 0 which means the gradient is normal to the curve at $(2, 1)$.

(c) The maximum rate of change at $(2, 1)$ is the magnitude of the gradient, so

$$\|16\mathbf{i} + 18\mathbf{j}\| = \sqrt{16^2 + 18^2} = \boxed{2\sqrt{145}}.$$

54. To verify that the level curves are orthogonal, it is enough to verify that their tangent lines are orthogonal at each point. The slope of the tangent line to the level curve $f(x, y) = x^2 - y^2 = k$ is found using implicit differentiation.

$$\begin{aligned} 2x - 2y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \frac{x}{y} \end{aligned}$$

The tangent line at a general point (x_0, y_0) to this level curve is then parallel to the vector $y_0\mathbf{i} + x_0\mathbf{j}$. The slope of the tangent line to the level curve $f(x, y) = xy = \ell$ is found using implicit differentiation.

$$\begin{aligned} y + x \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{y}{x} \end{aligned}$$

The tangent line at a general point (x_0, y_0) to this level curve is then parallel to the vector $-x_0\mathbf{i} + y_0\mathbf{j}$. To verify that these two vectors are orthogonal, we take their dot product

$$(y_0\mathbf{i} + x_0\mathbf{j}) \cdot (-x_0\mathbf{i} + y_0\mathbf{j}) = 0.$$

55. A general vector that is normal to the level curve of f through the point P is the gradient $\nabla f(1, -2)$. The gradient of f is

$$\nabla f(x, y) = 8xy\mathbf{i} + 4x^2\mathbf{j}$$

so $\nabla f(1, -2) = -16\mathbf{i} + 4\mathbf{j}$. If we want a unit vector $\mathbf{u}$ that is normal to the curve at this point, we will divide by the magnitude.

$$\mathbf{u} = \frac{1}{4\sqrt{17}}(-16\mathbf{i} + 4\mathbf{j}) = \boxed{-\frac{4\sqrt{17}}{17}\mathbf{i} + \frac{\sqrt{17}}{17}\mathbf{j}}$$

Another unit vector that is normal to the curve at the point P is

$$-\mathbf{u} = \boxed{\frac{4\sqrt{17}}{17}\mathbf{i} - \frac{\sqrt{17}}{17}\mathbf{j}}.$$

56. A general vector that is normal to the level curve of f through the point P is the gradient $\nabla f(1, 1)$. The gradient of f is

$$\nabla f(x, y) = 4x\mathbf{i} + 2y\mathbf{j}$$

so $\nabla f(1, 1) = 4\mathbf{i} + 2\mathbf{j}$. If we want a unit vector $\mathbf{u}$ that is normal to the curve at this point, we will divide by the magnitude.

$$\mathbf{u} = \frac{1}{2\sqrt{5}} (4\mathbf{i} + 2\mathbf{j}) = \boxed{\frac{2\sqrt{5}}{5}\mathbf{i} + \frac{\sqrt{5}}{5}\mathbf{j}}$$

Another unit vector that is normal to the curve at the point P is

$$-\mathbf{u} = \boxed{-\frac{2\sqrt{5}}{5}\mathbf{i} - \frac{\sqrt{5}}{5}\mathbf{j}}.$$

57. (a) The level curve for a general $T > 0$ is

$$\begin{aligned} \frac{250}{\sqrt{x^2 + y^2}} &= T \\ \sqrt{x^2 + y^2} &= \frac{250}{T} \\ x^2 + y^2 &= \left(\frac{250}{T}\right)^2 \end{aligned}$$

which is a circle centered at the origin of radius $\frac{250}{T}$.

(b) The level curves are drawn for $T = 25$, 50, and 250 with the smallest circle representing $T = 250$, the middle circle representing $T = 50$, and the largest circle representing $T = 25$.

(c) We have $T(-3, 4) = \frac{250}{\sqrt{(-3)^2 + (4)^2}} = 50$ so the level curve through $(-3, 4)$ is $\frac{250}{\sqrt{x^2 + y^2}} = 50$ or

$$\boxed{x^2 + y^2 = 25}.$$

(d) The gradient of $T(x, y) = 250(x^2 + y^2)^{-1/2}$ is

$$\nabla T(x, y) = -\frac{250x}{(x^2 + y^2)^{3/2}}\mathbf{i} - \frac{250y}{(x^2 + y^2)^{3/2}}\mathbf{j},$$

so

$$\boxed{\nabla T(-3, 4) = 6\mathbf{i} - 8\mathbf{j}}.$$

(e) An isothermal curve is a curve at which the temperature is the same for all points on the curve.

58. (a) The gradient of $z = -x^2 - y^2 + 5x$ is $\nabla z(x, y) = (-2x + 5)\mathbf{i} + (-2y)\mathbf{j}$. The unit vector in the northeast direction is $\mathbf{u} = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}$. The rate of change of altitude $D_{\mathbf{u}}z$ at the point $(1, 1, 3)$ is

$$\begin{aligned} D_{\mathbf{u}}z(1, 1) &= \nabla z(1, 1) \cdot \mathbf{u} = (3\mathbf{i} - 2\mathbf{j}) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j} \right) \\ &= \boxed{\frac{1}{\sqrt{2}}}. \end{aligned}$$

(b) The climber wants to start moving in the direction of maximum ascent from the point $(1, 2, 0)$ which is in the direction of the gradient at that point. So the climber should walk in the direction of

$$\nabla f(1, 2) = \boxed{3\mathbf{i} - 4\mathbf{j}}.$$

(c) To remain at the same altitude, there should be no change in z which means the climber should move in a direction perpendicular to the gradient at $(2, 1)$. The gradient at $(2, 1)$ is

$$\nabla f(2, 1) = \mathbf{i} - 2\mathbf{j}.$$

The directions perpendicular to this direction are $\boxed{\pm(2\mathbf{i} + \mathbf{j})}$.

59. The direction of greatest potential drop (i.e. the direction that a charge moves) from the point $(1, -1, 2)$ is in the opposite direction of the gradient at that point. The gradient is

$\nabla V(x, y, z) = yze^{xyz}\mathbf{i} + xze^{xyz}\mathbf{j} + xye^{xyz}\mathbf{k}$, so the charge moves in the following direction:

$$-\nabla V(1, -1, 2) = -(-2e^{-2}\mathbf{i} + 2e^{-2}\mathbf{j} - e^{-2}\mathbf{k}) = e^{-2}(2\mathbf{i} - 2\mathbf{j} + \mathbf{k}),$$

or, equivalently, in the direction of the unit vector

$$\mathbf{u} = \boxed{\frac{2}{3}\mathbf{i} - \frac{2}{3}\mathbf{j} + \frac{1}{3}\mathbf{k}}.$$

The charge is moving at a speed equal to directional derivative of V at $(1, -1, 2)$ in the direction $\mathbf{u}$, so the electrical potential changes at a rate of

$$\nabla V(1, -1, 2) \cdot \mathbf{u} = (-e^{-2}(2\mathbf{i} - 2\mathbf{j} + \mathbf{k})) \cdot \left(\frac{2}{3}\mathbf{i} - \frac{2}{3}\mathbf{j} + \frac{1}{3}\mathbf{k} \right) = \boxed{-3e^{-2} \text{ volts per unit change}}.$$

60. (a)

$$\begin{aligned} \mathbf{E} &= -\nabla V(x, y, z) = -\left(-\frac{kQx}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{i} - \frac{kQy}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{j} - \frac{kQz}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{k} \right) \\ &= \boxed{\frac{kQx}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{i} + \frac{kQy}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{j} + \frac{kQz}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{k}}. \end{aligned}$$

(b) If r is the distance from the origin to (x, y, z) , then $r^2 = x^2 + y^2 + z^2$. Then

$$\begin{aligned}\|\mathbf{E}\| &= \sqrt{\left(\frac{kQx}{(x^2 + y^2 + z^2)^{3/2}}\right)^2 + \left(\frac{kQy}{(x^2 + y^2 + z^2)^{3/2}}\right)^2 + \left(\frac{kQz}{(x^2 + y^2 + z^2)^{3/2}}\right)^2} \\ &= \sqrt{\frac{(kQ)^2 r^2}{r^6}} = \frac{kQ}{r^2}.\end{aligned}$$

(c) An equipotential surface looks like $\frac{kQ}{\sqrt{x^2 + y^2 + z^2}} = C$ for some constant C , which can be rewritten as

$$x^2 + y^2 + z^2 = \left(\frac{kQ}{C}\right)^2.$$

Let $f(x, y, z) = x^2 + y^2 + z^2 - \left(\frac{kQ}{C}\right)^2$. The tangent plane to f at the point (x_0, y_0, z_0) is given by $\nabla f(x_0, y_0, z_0) \cdot ((x - x_0)\mathbf{i} + (y - y_0)\mathbf{j} + (z - z_0)\mathbf{k}) = 0$, so any vector normal to the surface must be parallel to $\nabla f(x_0, y_0, z_0) = 2x_0\mathbf{i} + 2y_0\mathbf{j} + 2z_0\mathbf{k}$, or $x_0\mathbf{i} + y_0\mathbf{j} + z_0\mathbf{k}$. Note that $(x_0^2 + y_0^2 + z_0^2)^{3/2} = \left(\frac{kQ}{C}\right)^3 = C'$ for some constant C' . From part (a),

$$\mathbf{E}(x_0, y_0, z_0) = \frac{kQ}{C'}(x_0\mathbf{i} + y_0\mathbf{j} + z_0\mathbf{k}),$$

which means $\mathbf{E}(x_0, y_0, z_0)$ is parallel to $\nabla f(x_0, y_0, z_0)$, so $\mathbf{E}$ is normal to the surface at any point.

61. The vector from $(0, 1, 2)$ to the point $(2, 1, 2)$ is $(2, 0, 0)$ and the vector $\mathbf{i}$ is the unit vector in this same direction. So the rate of change of T in this direction is $\nabla T(x, y, z) \cdot \mathbf{i} = T_x(x, y, z) = -\frac{x}{\sqrt{9 - x^2 - y^2 - z^2}}$.

If we go straight from $(0, 1, 2)$ to $(2, 1, 2)$, then every point connecting these two points has $y = 1$ and $z = 2$. So a general point $(x, 1, 2)$ for $0 \leq x \leq 2$ has rate of change

$$\boxed{-\frac{x}{\sqrt{4 - x^2}}}.$$

62. First we find the gradient.

$$\nabla f(x, y, z) = -\frac{2x}{(x^2 + y^2 + z^2)^2}\mathbf{i} - \frac{2y}{(x^2 + y^2 + z^2)^2}\mathbf{j} - \frac{2z}{(x^2 + y^2 + z^2)^2}\mathbf{k}.$$

Since the cell will move in the direction of the gradient, the cell will move in the following direction

$$\nabla f(1, 2, 3) = \boxed{-\frac{1}{98}\mathbf{i} - \frac{1}{49}\mathbf{j} - \frac{3}{98}\mathbf{k}}.$$

63. The function $U_g(x, y, z) = mgz$ has gradient $\nabla U_g = 0\mathbf{i} + 0\mathbf{j} + mg\mathbf{k}$, so

$$\mathbf{F}_g = -\nabla U_g = -mg\mathbf{k}.$$

The gravitational force vector points in the negative z direction (i.e. downward) and has magnitude mg .

64. Since one object is at the origin and the other is at (x, y, z) , we have $r = \sqrt{x^2 + y^2 + z^2}$ so

$U_g = -G\frac{mM}{\sqrt{x^2 + y^2 + z^2}} = -GmM(x^2 + y^2 + z^2)^{-1/2}$. Computing the opposite of the gradient of U_g , we have

$$\begin{aligned}\mathbf{F}_g = -\nabla U_g &= -\frac{GmMx}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{i} - \frac{GmMy}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{j} - \frac{GmMz}{(x^2 + y^2 + z^2)^{3/2}}\mathbf{k} \\ &= -GmM\left(\frac{x}{r^3}\mathbf{i} + \frac{y}{r^3}\mathbf{j} + \frac{z}{r^3}\mathbf{k}\right).\end{aligned}$$

Now we compute the magnitude

$$\begin{aligned}\|\mathbf{F}_g\| &= |-GmM| \sqrt{\frac{x^2}{r^6} + \frac{y^2}{r^6} + \frac{z^2}{r^6}} \\ &= GmM \sqrt{\frac{r^2}{r^6}} = G \frac{mM}{r^2}.\end{aligned}$$

65. Since $\nabla f(x_0, y_0) = f_x(x_0, y_0)\mathbf{i} + f_y(x_0, y_0)\mathbf{j} \neq \mathbf{0}$, the two directions orthogonal to $\nabla f(x_0, y_0)$ are $\pm (f_y(x_0, y_0)\mathbf{i} - f_x(x_0, y_0)\mathbf{j})$. The two unit vectors in these directions are

$$\begin{aligned}\mathbf{u}_1 &= \frac{1}{\|\nabla f(x_0, y_0)\|} (f_y(x_0, y_0)\mathbf{i} - f_x(x_0, y_0)\mathbf{j}) \\ \mathbf{u}_2 &= \frac{1}{\|\nabla f(x_0, y_0)\|} (-f_y(x_0, y_0)\mathbf{i} + f_x(x_0, y_0)\mathbf{j}).\end{aligned}$$

Now we compute the directional derivatives in both unit vectors' directions.

$$\begin{aligned}D_{\mathbf{u}_1}f(x_0, y_0) &= \nabla f(x_0, y_0) \cdot \mathbf{u}_1 = (f_x(x_0, y_0)\mathbf{i} + f_y(x_0, y_0)\mathbf{j}) \cdot \frac{1}{\|\nabla f(x_0, y_0)\|} (f_y(x_0, y_0)\mathbf{i} - f_x(x_0, y_0)\mathbf{j}) \\ &= \frac{1}{\|\nabla f(x_0, y_0)\|} (f_x(x_0, y_0)f_y(x_0, y_0) - f_y(x_0, y_0)f_x(x_0, y_0)) = 0 \\ D_{\mathbf{u}_2}f(x_0, y_0) &= \nabla f(x_0, y_0) \cdot \mathbf{u}_2 = (f_x(x_0, y_0)\mathbf{i} + f_y(x_0, y_0)\mathbf{j}) \cdot \frac{1}{\|\nabla f(x_0, y_0)\|} (-f_y(x_0, y_0)\mathbf{i} + f_x(x_0, y_0)\mathbf{j}) \\ &= \frac{1}{\|\nabla f(x_0, y_0)\|} (-f_x(x_0, y_0)f_y(x_0, y_0) + f_y(x_0, y_0)f_x(x_0, y_0)) = 0\end{aligned}$$

66. (a)

$$\begin{aligned}\nabla(ku) &= \nabla(kf(x, y)) = kf_x(x, y)\mathbf{i} + kf_y(x, y)\mathbf{j} \\ &= k[f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}] = k\nabla u\end{aligned}$$

(b)

$$\begin{aligned}\nabla(u + v) &= \nabla(f(x, y) + g(x, y)) = [f_x(x, y) + g_x(x, y)]\mathbf{i} + [f_y(x, y) + g_y(x, y)]\mathbf{j} \\ &= [f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}] + [g_x(x, y)\mathbf{i} + g_y(x, y)\mathbf{j}] = \nabla u + \nabla v\end{aligned}$$

(c)

$$\begin{aligned}\nabla(uv) &= \nabla(f(x, y) \cdot g(x, y)) = [f_x(x, y) \cdot g(x, y) + f(x, y) \cdot g_x(x, y)]\mathbf{i} + [f_y(x, y) \cdot g(x, y) + f(x, y) \cdot g_y(x, y)]\mathbf{j} \\ &= [f(x, y) \cdot g_x(x, y)\mathbf{i} + f(x, y) \cdot g_y(x, y)\mathbf{j}] + [g(x, y) \cdot f_x(x, y)\mathbf{i} + g(x, y) \cdot f_y(x, y)\mathbf{j}] \\ &= f(x, y) [g_x(x, y)\mathbf{i} + g_y(x, y)\mathbf{j}] + g(x, y) [f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}] \\ &= u\nabla v + v\nabla u\end{aligned}$$

(d)

$$\begin{aligned}\nabla\left(\frac{u}{v}\right) &= \nabla\left(\frac{f(x, y)}{g(x, y)}\right) = \left(\frac{g(x, y)f_x(x, y) - f(x, y)g_x(x, y)}{(g(x, y))^2}\right)\mathbf{i} + \left(\frac{g(x, y)f_y(x, y) - f(x, y)g_y(x, y)}{(g(x, y))^2}\right)\mathbf{j} \\ &= \frac{g(x, y)f_x(x, y)\mathbf{i} - f(x, y)g_x(x, y)\mathbf{i} + g(x, y)f_y(x, y)\mathbf{j} - f(x, y)g_y(x, y)\mathbf{j}}{(g(x, y))^2} \\ &= \frac{g(x, y) [f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}] - f(x, y) [g_x(x, y)\mathbf{i} + g_y(x, y)\mathbf{j}]}{v^2} = \frac{v\nabla u - u\nabla v}{v^2}\end{aligned}$$

(e)

$$\begin{aligned}\nabla u^a &= \nabla (f(x, y))^a = (af(x, y)^{a-1}f_x(x, y))\mathbf{i} + (af(x, y)^{a-1}f_y(x, y))\mathbf{j} \\ &= af(x, y)^{a-1} [f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}] = au^{a-1}\nabla u\end{aligned}$$

67. Using formula (3)

$$\begin{aligned} D_{\mathbf{u}}f(x, y) &= \nabla f(x, y) \cdot \mathbf{u} = \left(\frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} \right) \cdot \frac{1}{\sqrt{a_1^2 + a_2^2}} (a_1 \mathbf{i} + a_2 \mathbf{j}) \\ &= \frac{a_1 \frac{\partial f}{\partial x} + a_2 \frac{\partial f}{\partial y}}{\sqrt{a_1^2 + a_2^2}}. \end{aligned}$$

68. If $F(x, y) = 0$, then taking the derivative with respect to x , we have $F_x(x, y) + F_y(x, y) \frac{dy}{dx} = 0$ so

$$\frac{dy}{dx} = -\frac{F_x(x, y)}{F_y(x, y)}.$$

The slope of the tangent line at (x_0, y_0) is $-\frac{F_x(x_0, y_0)}{F_y(x_0, y_0)}$. One vector that is parallel to the tangent line of $F(x, y) = 0$ at (x_0, y_0) is $F_y(x_0, y_0)\mathbf{i} - F_x(x_0, y_0)\mathbf{j}$. Now we show that the dot product between this vector and $\nabla F(x_0, y_0)$ is 0, which means that $\nabla F(x_0, y_0)$ is normal to $F(x, y) = 0$ at (x_0, y_0) .

$$(F_y(x_0, y_0)\mathbf{i} - F_x(x_0, y_0)\mathbf{j}) \cdot \nabla F(x_0, y_0) = (F_y(x_0, y_0)\mathbf{i} - F_x(x_0, y_0)\mathbf{j}) \cdot (F_x(x_0, y_0)\mathbf{i} + F_y(x_0, y_0)\mathbf{j}) = 0$$

69. In Problem 68, we showed that $F_y(x_0, y_0)\mathbf{i} - F_x(x_0, y_0)\mathbf{j}$ is a vector parallel to the tangent line of $F(x, y) = 0$ at (x_0, y_0) . If $b = F_y(x_0, y_0) \neq 0$, then the slope of this tangent line is $-\frac{F_x(x_0, y_0)}{F_y(x_0, y_0)}$. Using point-slope form, the equation of the tangent line is

$$\begin{aligned} y - y_0 &= -\frac{F_x(x_0, y_0)}{F_y(x_0, y_0)}(x - x_0) \\ F_y(x_0, y_0)(y - y_0) &= -F_x(x_0, y_0)(x - x_0) \\ a(x - x_0) + b(y - y_0) &= 0. \end{aligned}$$

If $b = F_y(x_0, y_0) = 0$, then we know that $a = F_x(x_0, y_0) \neq 0$ so the tangent line is vertical since it must be parallel to the vector $F_y(x_0, y_0)\mathbf{i} - F_x(x_0, y_0)\mathbf{j} = -F_x(x_0, y_0)\mathbf{j}$. This means the tangent line is

$$\begin{aligned} x - x_0 &= 0 \\ a(x - x_0) + 0(y - y_0) &= 0 \\ a(x - x_0) + b(y - y_0) &= 0. \end{aligned}$$

70. (a) Using Problem 69, $F(x, y) = x^2 - y^2 - 16$, so $F_x(x, y) = 2x$ and $F_y(x, y) = -2y$. Then the tangent line is

$$\begin{aligned} F_x(5, 3)(x - 5) + F_y(5, 3)(y - 3) &= 0 \\ 10(x - 5) - 6(y - 3) &= 0 \\ y &= \frac{5}{3}x - \frac{16}{3}. \end{aligned}$$

If we use implicit differentiation, then

$$\begin{aligned} 2x - 2y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \frac{x}{y} \\ \frac{dy}{dx} \Big|_{(5, 3)} &= \frac{5}{3}, \end{aligned}$$

which agrees with the slope we found using Problem 69.

(b) The tangent line is

$$\begin{aligned} F_x(4,0)(x-4) + F_y(4,0)(y-0) &= 0 \\ 8(x-4) &= 0 \\ x &= 4. \end{aligned}$$

71. No, f is not necessarily differentiable. One example of such a function is $f(x, y) = (x^2y)^{1/3}$. Note that $D_{\mathbf{u}}f(0,0)$ in the direction of $\mathbf{u} = \cos\theta\mathbf{i} + \sin\theta\mathbf{j}$ is $(\cos^2\theta\sin\theta)^{1/3}$. Also, $f_x(0,0) = f_y(0,0) = 0$. If f were differentiable at $(0,0)$, then $D_{\mathbf{u}}f(0,0)$ would equal $\nabla f(0,0) \cdot \mathbf{u} = 0$ for every unit vector $\mathbf{u}$. However, $D_{\mathbf{u}}f(0,0) = (\cos^2\theta\sin\theta)^{1/3}$ is not identically zero, so f is not differentiable at the origin.

72. The points on the line $x-1 = y-2 = z-1$ can be parametrized by $(x(t), y(t), z(t)) = (t, t+1, t)$ which points in the direction $\mathbf{i} + \mathbf{j} + \mathbf{k}$. The unit vector in this direction is $\mathbf{u} = \frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k}$. Now the gradient of f is $\nabla f(x, y, z) = 3z\mathbf{i} - 2y\mathbf{j} + (3z^2 + 3x)\mathbf{k}$, so the directional derivative at $(1, 2, 1)$ in the direction of $\mathbf{u}$ is

$$\begin{aligned} D_{\mathbf{u}}f(1, 2, 1) &= \nabla f(1, 2, 1) \cdot \mathbf{u} = (3\mathbf{i} - 4\mathbf{j} + 6\mathbf{k}) \cdot \left(\frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k} \right) \\ &= \boxed{\frac{5}{\sqrt{3}}}. \end{aligned}$$

Similarly, we obtain $\boxed{-\frac{5}{\sqrt{3}}}$ if we use $-\mathbf{u}$ for the direction of the line.

Challenge Problems

73. (a) Since $r = \sqrt{x^2 + y^2} = (x^2 + y^2)^{1/2}$, we have $r^n = (x^2 + y^2)^{n/2}$. Then

$$\begin{aligned} \nabla r^n &= \frac{n}{2} (x^2 + y^2)^{n/2-1} \cdot 2x\mathbf{i} + \frac{n}{2} (x^2 + y^2)^{n/2-1} \cdot 2y\mathbf{j} \\ &= nx \left(\sqrt{x^2 + y^2} \right)^{n-2} \mathbf{i} + ny \left(\sqrt{x^2 + y^2} \right)^{n-2} \mathbf{j} = n \left(\sqrt{x^2 + y^2} \right)^{n-2} (x\mathbf{i} + y\mathbf{j}) \\ &= nr^{n-2} \mathbf{r}. \end{aligned}$$

(b) Using the Chain Rule

$$\begin{aligned} g_x(r) &= g'(r) \cdot r_x = g'(r) \cdot (x^2 + y^2)^{-1/2} \cdot x = \frac{g'(r)}{r} x \\ g_y(r) &= g'(r) \cdot r_y = g'(r) \cdot (x^2 + y^2)^{-1/2} \cdot y = \frac{g'(r)}{r} y. \end{aligned}$$

Then

$$\nabla g(r) = g_x(r)\mathbf{i} + g_y(r)\mathbf{j} = \frac{g'(r)}{r} (x\mathbf{i} + y\mathbf{j}) = \frac{g'(r)}{r} \mathbf{r}.$$

(c) Using formula (3) and part (b)

$$D_{\mathbf{u}}[g(r)] = \nabla g(r) \cdot \mathbf{u} = \frac{g'(r)}{r} \mathbf{r} \cdot \mathbf{u} = \frac{g'(r)}{r} (\mathbf{r} \cdot \mathbf{u}).$$

(d) Let $f(x, y) = \frac{x}{r} = \frac{x}{\sqrt{x^2 + y^2}} = x(x^2 + y^2)^{-1/2}$. Then

$$\begin{aligned} f_x(x, y) &= (x^2 + y^2)^{-1/2} - x^2 (x^2 + y^2)^{-3/2} = (x^2 + y^2)^{-3/2} ((x^2 + y^2) - x^2) \\ &= \frac{y^2}{(x^2 + y^2)^{3/2}} = \frac{y^2}{r^3} \\ f_y(x, y) &= -xy (x^2 + y^2)^{-3/2} = -\frac{xy}{(x^2 + y^2)^{3/2}} = -\frac{xy}{r^3}. \end{aligned}$$

Now,

$$\begin{aligned}
 \frac{\mathbf{i}}{r} - \left(\frac{x}{r}\right) \left(\frac{\mathbf{r}}{r^2}\right) &= \frac{1}{r} \mathbf{i} - \left(\frac{x}{r^3}\right) (x\mathbf{i} + y\mathbf{j}) = \left(\frac{1}{r} - \frac{x^2}{r^3}\right) \mathbf{i} - \frac{xy}{r^3} \mathbf{j} \\
 &= \frac{r^2 - x^2}{r^3} \mathbf{i} - \frac{xy}{r^3} \mathbf{j} = \frac{y^2}{r^3} \mathbf{i} - \frac{xy}{r^3} \mathbf{j} \\
 &= f_x(x, y) \mathbf{i} + f_y(x, y) \mathbf{j} = \nabla f(x, y) \\
 &= \nabla \left(\frac{x}{r}\right).
 \end{aligned}$$

74. To compute the directional derivative at $(0, 0)$, we need to first compute $f_x(0, 0)$ and $f_y(0, 0)$ which we will compute using the definition of the partial derivative. In each step where the equal symbol is labelled with an asterisk (*), we used L'Hopital's Rule.

$$\begin{aligned}
 f_x(0, 0) &= \lim_{h \rightarrow 0} \frac{f(0 + h, 0) - f(0, 0)}{h} = \lim_{h \rightarrow 0} \frac{\frac{\sin(h^2)}{h^2} - 1}{h} \\
 &= \lim_{h \rightarrow 0} \frac{\sin(h^2) - h^2}{h^3} \stackrel{*}{=} \lim_{h \rightarrow 0} \frac{\cos(h^2) \cdot 2h - 2h}{3h^2} = \lim_{h \rightarrow 0} \frac{2\cos(h^2) - 2}{3h} \\
 &\stackrel{*}{=} \lim_{h \rightarrow 0} \frac{-2\sin(h^2) \cdot 2h}{3} = 0
 \end{aligned}$$

Similarly

$$f_y(0, 0) = \lim_{h \rightarrow 0} \frac{f(0, 0 + h) - f(0, 0)}{h} = \lim_{h \rightarrow 0} \frac{\frac{\sin(h^2)}{h^2} - 1}{h} = 0$$

Since $f_x(0, 0) = 0 = f_y(0, 0)$, the directional derivative in any direction at $(0, 0)$ is 0.

75. Since $\nabla f(x, y) = c(x\mathbf{i} + y\mathbf{j})$ we have that $f_x(x, y) = cx$ and $f_y(x, y) = cy$. By integrating f_x with respect to x , we find that $f(x, y) = \frac{1}{2}cx^2 + g(y)$ for some function g depending only on y . Differentiating $f(x, y) = \frac{1}{2}cx^2 + g(y)$ with respect to y gives

$$cy = f_y(x, y) = g'(y)$$

which means $g(y) = \frac{1}{2}cy^2 + C$ for some constant C . Putting this all together, we find that

$$f(x, y) = \frac{1}{2}cx^2 + \frac{1}{2}cy^2 + C = \frac{1}{2}c(x^2 + y^2) + C.$$

If (x_0, y_0) lies on a circle centered at $(0, 0)$ of radius k , then $x_0^2 + y_0^2 = k^2$ so plugging this point into f , we find that

$$f(x_0, y_0) = \frac{1}{2}c(x_0^2 + y_0^2) + C = \frac{1}{2}ck^2 + C,$$

which is a constant.

76. For the gradient to be normal to the level surface f through P_0 means that it is perpendicular to any curve that lies on the surface and goes through P_0 . Suppose that some curve on the surface $f(x, y, z) = k$ goes through P_0 and is represented parametrically by $x = x(t)$, $y = y(t)$, and $z = z(t)$, with $x_0 = x(t_0)$, $y_0 = y(t_0)$, and $z_0 = z(t_0)$. Then

$$f(x(t), y(t), z(t)) = k.$$

Differentiating with respect to t , we get

$$f_x(x(t), y(t), z(t)) \cdot x'(t) + f_y(x(t), y(t), z(t)) \cdot y'(t) + f_z(x(t), y(t), z(t)) \cdot z'(t) = 0,$$

or, equivalently,

$$\nabla f(x, y, z) \cdot [x'(t)\mathbf{i} + y'(t)\mathbf{j} + z'(t)\mathbf{k}] = 0.$$

We know that $x'(t_0)\mathbf{i} + y'(t_0)\mathbf{j} + z'(t_0)\mathbf{k}$ is tangent to the curve at the point P_0 , so $\nabla f(x_0, y_0, z_0)$ is normal to any curve on the surface, which then means it is normal to the surface at point P_0 .

77. Since $g(x, y) = D_{\mathbf{u}}f(x, y)$ we know that

$$g(x, y) = u_1 f_x(x, y) + u_2 f_y(x, y).$$

Then using formula(3) again to compute $D_{\mathbf{u}}g(x, y)$, we have

$$\begin{aligned} D_{\mathbf{u}}g(x, y) &= v_1 g_x(x, y) + v_2 g_y(x, y) \\ &= v_1 (u_1 f_{xx}(x, y) + u_2 f_{yx}(x, y)) + v_2 (u_1 f_{xy}(x, y) + u_2 f_{yy}(x, y)) \\ &= u_1 v_1 f_{xx}(x, y) + (u_1 v_2 + u_2 v_1) f_{xy}(x, y) + u_2 v_2 f_{yy}(x, y) \end{aligned}$$

where in the last step we used that $f_{xy} = f_{yx}$ since f has continuous second-order partial derivatives.

78. In Problem 68, we showed that $F_y(x_0, y_0)\mathbf{i} - F_x(x_0, y_0)\mathbf{j}$ is a vector parallel to the tangent line of $F(x, y) = 0$ at (x_0, y_0) . If $b = F_y(x_0, y_0) \neq 0$, then the slope of the tangent line is $m = -\frac{F_x(x_0, y_0)}{F_y(x_0, y_0)}$.

13.2 Tangent Planes

Concepts and Vocabulary

1. **True**. The tangent plane has equation $\nabla F(x_0, y_0, z_0) \cdot [(x - x_0)\mathbf{i} + (y - y_0)\mathbf{j} + (z - z_0)\mathbf{k}] = 0$.

2. **True**.

Skill Building

3. Using the formula at the end of the section, an equation of the tangent plane is $z - z_0 = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$. The partial derivatives and their values at the given point are as follows

$$\begin{aligned} f_x(x, y) &= -4x & \text{and} & & f_y(x, y) &= -2y \\ f_x(0, 2) &= 0 & \text{and} & & f_y(0, 2) &= -4 \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} z - 6 &= 0(x - 0) - 4(y - 2) \\ 4y + z &= 14. \end{aligned}$$

4. Using the formula at the end of the section, an equation of the tangent plane is $z - z_0 = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$. The partial derivatives and their values at the given point are as follows

$$\begin{aligned} f_x(x, y) &= 2x & \text{and} & & f_y(x, y) &= 2y \\ f_x(1, -2) &= 2 & \text{and} & & f_y(1, -2) &= -4 \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} z - 9 &= 2(x - 1) - 4(y + 2) \\ -2x + 4y + z &= -1. \end{aligned}$$

5. Using the formula at the end of the section, an equation of the tangent plane is $z - z_0 = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$. The partial derivatives and their values at the given point are as follows

$$\begin{aligned} f_x(x, y) &= 8x & \text{and} & & f_y(x, y) &= 18y \\ f_x(1, 1) &= 8 & \text{and} & & f_y(1, 1) &= 18 \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} z - 13 &= 8(x - 1) + 18(y - 1) \\ 8x + 18y - z &= 13. \end{aligned}$$

6. Using the formula at the end of the section, an equation of the tangent plane is $z - z_0 = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$. The partial derivatives and their values at the given point are as follows

$$\begin{aligned} f_x(x, y) &= \frac{x}{\sqrt{x^2 + 3y^2}} & \text{and} & & f_y(x, y) &= \frac{3y}{\sqrt{x^2 + 3y^2}} \\ f_x(1, 1) &= \frac{1}{2} & \text{and} & & f_y(1, 1) &= \frac{3}{2} \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} z - 2 &= \frac{1}{2}(x - 1) + \frac{3}{2}(y - 1) \\ -\frac{1}{2}x - \frac{3}{2}y + z &= 0. \end{aligned}$$

7. (a) To use the theorem from this section with $F(x, y, z) = x^2 + y^2 + z^2 - 14 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(1, -2, 3) = 2 \\ F_y(x, y, z) = 2y & F_y(1, -2, 3) = -4 \\ F_z(x, y, z) = 2z & F_z(1, -2, 3) = 6 \end{array}$$

Then an equation of the tangent plane is

$$2(x - 1) - 4(y + 2) + 6(z - 3) = 0$$

$$\boxed{x - 2y + 3z = 14}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x - 1}{1} = \frac{y + 2}{-2} = \frac{z - 3}{3}}.$$

8. (a) To use the theorem from this section with $F(x, y, z) = 2x^2 + 3y^2 + z^2 - 12 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 4x & F_x(2, 1, -1) = 8 \\ F_y(x, y, z) = 6y & F_y(2, 1, -1) = 6 \\ F_z(x, y, z) = 2z & F_z(2, 1, -1) = -2 \end{array}$$

Then an equation of the tangent plane is

$$8(x - 2) + 6(y - 1) - 2(z + 1) = 0$$

$$\boxed{4x + 3y - z = 12}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x - 2}{4} = \frac{y - 1}{3} = \frac{z + 1}{-1}}.$$

9. (a) To use the theorem from this section with $F(x, y, z) = 4x^2 + y^2 - 2z^2 - 3 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 8x & F_x(1, 1, -1) = 8 \\ F_y(x, y, z) = 2y & F_y(1, 1, -1) = 2 \\ F_z(x, y, z) = -4z & F_z(1, 1, -1) = 4 \end{array}$$

Then an equation of the tangent plane is

$$8(x - 1) + 2(y - 1) + 4(z + 1) = 0$$

$$\boxed{4x + y + 2z = 3}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x - 1}{4} = \frac{y - 1}{1} = \frac{z + 1}{2}}.$$

10. (a) To use the theorem from this section with $F(x, y, z) = x^2 + 3y^2 - z^2 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(1, -1, -2) = 2 \\ F_y(x, y, z) = 6y & F_y(1, -1, -2) = -6 \\ F_z(x, y, z) = -2z & F_z(1, -1, -2) = 4 \end{array}$$

Then an equation of the tangent plane is

$$2(x-1) - 6(y+1) + 4(z+2) = 0$$

$$\boxed{x - 3y + 2z = 0}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-1}{1} = \frac{y+1}{-3} = \frac{z+2}{2}}.$$

11. (a) To use the theorem from this section with $F(x, y, z) = x^2 + y^2 - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(-2, 1, 5) = -4 \\ F_y(x, y, z) = 2y & F_y(-2, 1, 5) = 2 \\ F_z(x, y, z) = -1 & F_z(-2, 1, 5) = -1 \end{array}$$

Then an equation of the tangent plane is

$$-4(x+2) + 2(y-1) - 1(z-5) = 0$$

$$\boxed{4x - 2y + z = -5}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x+2}{-4} = \frac{y-1}{2} = \frac{z-5}{-1}}.$$

12. (a) To use the theorem from this section with $F(x, y, z) = 2x^2 - 3y^2 - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 4x & F_x(2, 1, 5) = 8 \\ F_y(x, y, z) = -6y & F_y(2, 1, 5) = -6 \\ F_z(x, y, z) = -1 & F_z(2, 1, 5) = -1 \end{array}$$

Then an equation of the tangent plane is

$$8(x-2) - 6(y-1) - 1(z-5) = 0$$

$$\boxed{8x - 6y - z = 5}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-2}{8} = \frac{y-1}{-6} = \frac{z-5}{-1}}.$$

13. (a) To use the theorem from this section with $F(x, y, z) = 2x^2 - y^2 - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 4x & F_x(1, 0, 2) = 4 \\ F_y(x, y, z) = -2y & F_y(1, 0, 2) = 0 \\ F_z(x, y, z) = -1 & F_z(1, 0, 2) = -1 \end{array}$$

Then an equation of the tangent plane is

$$4(x-1) + 0(y-0) - 1(z-2) = 0$$

$$\boxed{4x - z = 2}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-1}{4} = \frac{z-2}{-1}; y=0}.$$

14. (a) To use the theorem from this section with $F(x, y, z) = x^2 + y^2 - 2z^2 + 13 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(2, 1, 3) = 4 \\ F_y(x, y, z) = 2y & F_y(2, 1, 3) = 2 \\ F_z(x, y, z) = -4z & F_z(2, 1, 3) = -12 \end{array}$$

Then an equation of the tangent plane is

$$4(x-2) + 2(y-1) - 12(z-3) = 0$$

$$\boxed{2x + y - 6z = -13}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-2}{2} = \frac{y-1}{1} = \frac{z-3}{-6}}.$$

15. (a) To use the theorem from this section with $F(x, y, z) = x^2 - 3y^2 - 4z^2 - 2 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(3, 1, 1) = 6 \\ F_y(x, y, z) = -6y & F_y(3, 1, 1) = -6 \\ F_z(x, y, z) = -8z & F_z(3, 1, 1) = -8 \end{array}$$

Then an equation of the tangent plane is

$$6(x-3) - 6(y-1) - 8(z-1) = 0$$

$$\boxed{3x - 3y - 4z = 2}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-3}{3} = \frac{y-1}{-3} = \frac{z-1}{-4}}.$$

16. (a) To use the theorem from this section with $F(x, y, z) = x^2 + 2y^2 - 5z^2 - 4 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(1, 2, 1) = 2 \\ F_y(x, y, z) = 4y & F_y(1, 2, 1) = 8 \\ F_z(x, y, z) = -10z & F_z(1, 2, 1) = -10 \end{array}$$

Then an equation of the tangent plane is

$$2(x-1) + 8(y-2) - 10(z-1) = 0$$

$$\boxed{x + 4y - 5z = 4}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-1}{1} = \frac{y-2}{4} = \frac{z-1}{-5}}.$$

17. (a) To use the theorem from this section with $F(x, y, z) = \ln(\sec(x^2 + y^2)) - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{aligned} F_x(x, y, z) &= \frac{1}{\sec(x^2 + y^2)} \cdot \sec(x^2 + y^2) \tan(x^2 + y^2) \cdot 2x = 2x \tan(x^2 + y^2) \\ F_x\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}, \ln \sqrt{2}\right) &= 2\sqrt{\frac{\pi}{8}} \tan \frac{\pi}{4} = \frac{\sqrt{\pi}}{\sqrt{2}} \\ F_y(x, y, z) &= \frac{1}{\sec(x^2 + y^2)} \cdot \sec(x^2 + y^2) \tan(x^2 + y^2) \cdot 2y = 2y \tan(x^2 + y^2) \\ F_y\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}, \ln \sqrt{2}\right) &= 2\sqrt{\frac{\pi}{8}} \tan \frac{\pi}{4} = \frac{\sqrt{\pi}}{\sqrt{2}} \\ F_z(x, y, z) &= -1 \\ F_z\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}, \ln \sqrt{2}\right) &= -1 \end{aligned}$$

Then an equation of the tangent plane is

$$\frac{\sqrt{\pi}}{\sqrt{2}} \left(x - \sqrt{\frac{\pi}{8}}\right) + \frac{\sqrt{\pi}}{\sqrt{2}} \left(y - \sqrt{\frac{\pi}{8}}\right) - 1(z - \ln \sqrt{2}) = 0$$

$$\frac{\sqrt{\pi}}{\sqrt{2}}x + \frac{\sqrt{\pi}}{\sqrt{2}}y - z = \frac{\pi}{2} - \ln \sqrt{2}.$$

(b) Symmetric equations of the normal line are

$$\frac{x - \sqrt{\frac{\pi}{8}}}{\frac{\sqrt{\pi}}{\sqrt{2}}} = \frac{y - \sqrt{\frac{\pi}{8}}}{\frac{\sqrt{\pi}}{\sqrt{2}}} = \frac{z - \ln \sqrt{2}}{-1}.$$

18. (a) To use the theorem from this section with $F(x, y, z) = \frac{x^2 - y^2}{x^2 + y^2} - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{aligned} F_x(x, y, z) &= \frac{(x^2 + y^2) \cdot 2x - (x^2 - y^2) \cdot 2x}{(x^2 + y^2)^2} = \frac{4xy^2}{(x^2 + y^2)^2} \\ F_x\left(1, 2, -\frac{3}{5}\right) &= \frac{16}{25} \\ F_y(x, y, z) &= \frac{(x^2 + y^2) \cdot (-2y) - (x^2 - y^2) \cdot 2y}{(x^2 + y^2)^2} = -\frac{4yx^2}{(x^2 + y^2)^2} \\ F_y\left(1, 2, -\frac{3}{5}\right) &= -\frac{8}{25} \\ F_z(x, y, z) &= -1 \\ F_z\left(1, 2, -\frac{3}{5}\right) &= -1 \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} \frac{16}{25}(x - 1) - \frac{8}{25}(y - 2) - \left(z + \frac{3}{5}\right) &= 0 \\ \frac{16}{25}x - \frac{8}{25}y - z &= \frac{3}{5} \\ \boxed{16x - 8y - 25z = 15}. \end{aligned}$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-1}{16} = \frac{y-2}{-8} = \frac{z+\frac{3}{5}}{-25}}.$$

19. (a) To use the theorem from this section with $F(x, y, z) = e^x \cos y - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{aligned} F_x(x, y, z) &= e^x \cos y & F_x\left(0, \frac{\pi}{2}, 0\right) &= 0 \\ F_y(x, y, z) &= -e^x \sin y & F_y\left(0, \frac{\pi}{2}, 0\right) &= -1 \\ F_z(x, y, z) &= -1 & F_z\left(0, \frac{\pi}{2}, 0\right) &= -1 \end{aligned}$$

Then an equation of the tangent plane is

$$0(x-0) - 1\left(y - \frac{\pi}{2}\right) - 1(z-0) = 0$$

$$\boxed{y + z = \frac{\pi}{2}}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{y - \frac{\pi}{2}}{-1} = \frac{z}{-1}; x = 0}.$$

(c)

20. (a) To use the theorem from this section with $F(x, y, z) = \ln(x^2 + y^2) - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{aligned} F_x(x, y, z) &= \frac{2x}{x^2 + y^2} & F_x(1, -1, \ln 2) &= 1 \\ F_y(x, y, z) &= \frac{2y}{x^2 + y^2} & F_y(1, -1, \ln 2) &= -1 \\ F_z(x, y, z) &= -1 & F_z(1, -1, \ln 2) &= -1 \end{aligned}$$

Then an equation of the tangent plane is

$$1(x-1) - 1(y+1) - 1(z - \ln 2) = 0$$

$$\boxed{x - y - z = 2 - \ln 2}.$$

(b) Symmetric equations of the normal line are

$$\frac{x-1}{1} = \frac{y+1}{-1} = \frac{z-\ln 2}{-1}.$$

(c)

21. (a) To use the theorem from this section with $F(x, y, z) = x^{2/3} + y^{2/3} + z^{2/3} - 9 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{aligned} F_x(x, y, z) &= \frac{2}{3}x^{-1/3} & F_x(1, 8, -8) &= \frac{2}{3} \\ F_y(x, y, z) &= \frac{2}{3}y^{-1/3} & F_y(1, 8, -8) &= \frac{1}{3} \\ F_z(x, y, z) &= \frac{2}{3}z^{-1/3} & F_z(1, 8, -8) &= -\frac{1}{3} \end{aligned}$$

Then an equation of the tangent plane is

$$\frac{2}{3}(x-1) + \frac{1}{3}(y-8) - \frac{1}{3}(z+8) = 0$$

$$\boxed{2x + y - z = 18}.$$

(b) Symmetric equations of the normal line are

$$\frac{x-1}{2} = \frac{y-8}{1} = \frac{z+8}{-1}.$$

(c)

22. (a) To use the theorem from this section with $F(x, y, z) = x^{1/2} + y^{1/2} + z^{1/2} - 6 = 0$, we begin by

finding the partial derivatives of F and their values at the given point.

$$\begin{aligned} F_x(x, y, z) &= \frac{1}{2}x^{-1/2} & F_x(1, 4, 9) &= \frac{1}{2} \\ F_y(x, y, z) &= \frac{1}{2}y^{-1/2} & F_y(1, 4, 9) &= \frac{1}{4} \\ F_z(x, y, z) &= \frac{1}{2}z^{-1/2} & F_z(1, 4, 9) &= \frac{1}{6} \end{aligned}$$

Then an equation of the tangent plane is

$$\frac{1}{2}(x-1) + \frac{1}{4}(y-4) + \frac{1}{6}(z-9) = 0$$

$$\boxed{6x + 3y + 2z = 36}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x-1}{6} = \frac{y-4}{3} = \frac{z-9}{2}}.$$

(c)

Applications and Extensions

23. Using $z = f(x, y) = \sqrt{x^2 + y^2 - 24}$, the partial derivatives and their values at the point $(3, -4, 1)$ are as follows

$$\begin{aligned} f_x(x, y) &= \frac{x}{\sqrt{x^2 + y^2 - 24}} & \text{and} & & f_y(x, y) &= \frac{y}{\sqrt{x^2 + y^2 - 24}} \\ f_x(3, -4) &= 3 & \text{and} & & f_y(3, -4) &= -4 \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} z - 1 &= 3(x - 3) - 4(y + 4) \\ 3x - 4y - z &= 24, \end{aligned}$$

which agrees with Example 1.

24. In Problem 23, we found the coefficients of x , y , and z of the tangent plane to be 3, -4 , and -1 , respectively. This means that symmetric equations of the normal line at the point $(3, -4, 1)$ are

$$\frac{x-3}{3} = \frac{y+4}{-4} = \frac{z-1}{-1},$$

which agrees with Example 2.

25. We will use the fact that the tangent plane is parallel to the xy -plane at $P = (x_0, y_0)$ when the normal line at P is perpendicular to the xy -plane, or, equivalently, when $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Finding the partial derivatives of f and setting them equal to 0, we have

$$\begin{aligned} f_x(x, y) &= 6 - 2x = 0 \\ f_y(x, y) &= -4 - 4y = 0. \end{aligned}$$

The only point that simultaneously makes both partial derivatives vanish is $(3, -1)$. This means that $(3, -1, 11)$ is the only point where the tangent plane is parallel to the xy -plane.

26. We will use the fact that the tangent plane is parallel to the xy -plane at $P = (x_0, y_0)$ when the normal line at P is perpendicular to the xy -plane, or, equivalently, when $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Finding the partial derivatives of f and setting them equal to 0, we have

$$\begin{aligned} f_x(x, y) &= 4 + 2x = 0 \\ f_y(x, y) &= -2 + 2y = 0. \end{aligned}$$

The only point that simultaneously makes both partial derivatives vanish is $(-2, 1)$. This means that $(-2, 1, -5)$ is the only point where the tangent plane is parallel to the xy -plane.

27. We will use the fact that the tangent plane is parallel to the xy -plane at $P = (x_0, y_0)$ when the normal line at P is perpendicular to the xy -plane, or, equivalently, when $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Finding the partial derivatives of f and setting them equal to 0, we have

$$\begin{aligned} f_x(x, y) &= 2x + 2y = 0 \\ f_y(x, y) &= 2x + 2y = 0. \end{aligned}$$

Every point $(x, -x)$ makes both partial derivatives vanish. This means that there are an infinite number of points where the tangent plane is parallel to the xy -plane, and they are $(x, -x, 0)$ for any real number x .

28. We will use the fact that the tangent plane is parallel to the xy -plane at $P = (x_0, y_0)$ when the normal line at P is perpendicular to the xy -plane, or, equivalently, when $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Finding the partial derivatives of f and setting them equal to 0, we have

$$\begin{aligned} f_x(x, y) &= 2x - 3y = 0 \\ f_y(x, y) &= -3x + 2y = 0. \end{aligned}$$

Solving the f_x equation for x and substituting it into the f_y equation, we have

$$\begin{aligned} -3\left(\frac{3y}{2}\right) + 2y &= 0 \\ y &= 0, \end{aligned}$$

so $x = 0$ too. This means that $(0, 0, 0)$ is the only point where the tangent plane is parallel to the xy -plane.

29. We will use the fact that the tangent plane is parallel to the xy -plane at $P = (x_0, y_0)$ when the normal line at P is perpendicular to the xy -plane, or, equivalently, when $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Finding the partial derivatives of f and setting them equal to 0, we have

$$\begin{aligned} f_x(x, y) &= 8x^3 - 2x = 0 \\ f_y(x, y) &= -2y - 2 = 0. \end{aligned}$$

Factoring the first equation, we have

$$\begin{aligned} 2x(4x^2 - 1) &= 0 \\ x &= 0, \pm \frac{1}{2}, \end{aligned}$$

and solving the second equation $y = -1$. So the points where the tangent plane is parallel to the x -plane are

$$\left(0, -1, 1\right), \left(\frac{1}{2}, -1, \frac{7}{8}\right), \left(-\frac{1}{2}, -1, \frac{7}{8}\right).$$

30. We will use the fact that the tangent plane is parallel to the xy -plane at $P = (x_0, y_0)$ when the normal line at P is perpendicular to the xy -plane, or, equivalently, when $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Finding the partial derivatives of f and setting them equal to 0, we have

$$\begin{aligned} f_x(x, y) &= 2x - 2 = 0 \\ f_y(x, y) &= 4y^3 - 8y = 0. \end{aligned}$$

From the f_x equation, we see that $x = 1$. Factoring the f_y equation, we have

$$\begin{aligned} 4y(y^2 - 2) &= 0 \\ y &= 0, \pm\sqrt{2}. \end{aligned}$$

So the points where the tangent plane is parallel to the x -plane are $\left(1, 0, -1\right), \left(1, \sqrt{2}, -5\right), \left(1, -\sqrt{2}, -5\right)$.

31. She should bolt the solar panel in the direction of the normal line, which is in the direction of the gradient of $F(x, y, z) = 4 - x^2 - y^2 - z$ at the point $(1, 1, 2)$. Since $\nabla F(x, y, z) = -2x\mathbf{i} - 2y\mathbf{j} - \mathbf{k}$, she should bolt in the direction of $\nabla F(1, 1, 2) = -2\mathbf{i} - 2\mathbf{j} - \mathbf{k}$.

32. (a) To find the tangent plane of the first equation, we will call the left side of the equation $F(x, y, z)$. Now we find the partial derivatives of F and their values at the point $(0, -1, 2)$.

$$\begin{aligned} F_x(x, y, z) &= 2x & F_x(0, -1, 2) &= 0 \\ F_y(x, y, z) &= 4 & F_y(0, -1, 2) &= 4 \\ F_z(x, y, z) &= 2z & F_z(0, -1, 2) &= 4 \end{aligned}$$

The equation of the tangent plane is then

$$\begin{aligned} 0(x - 0) - 4(y + 1) - 4(z - 2) &= 0 \\ 4y + 4z &= 4 \end{aligned}$$

To find the tangent plane of the second equation, we will call the left side of the equation $G(x, y, z)$. Now we find the partial derivatives of F and their values at the point $(0, -1, 2)$.

$$\begin{aligned} G_x(x, y, z) &= 2x & G_x(0, -1, 2) &= 0 \\ G_y(x, y, z) &= 2y & G_y(0, -1, 2) &= -2 \\ G_z(x, y, z) &= 2z - 6 & G_z(0, -1, 2) &= -2 \end{aligned}$$

The equation of the tangent plane is then

$$\begin{aligned} 0(x - 0) - 2(y + 1) - 2(z - 2) &= 0 \\ 2y + 2z &= 2 \end{aligned}$$

Both tangent planes are the same, so the two surfaces are tangent at the common point.

(b)

33. (a) To find the points of intersection, we solve for $x^2 + y^2$ in the first equation and plug it into the second. Then

$$\begin{aligned}(1 - z^2) - z^2 &= 1 \\ z &= 0.\end{aligned}$$

This means the two surfaces intersect in the xy -plane when $x^2 + y^2 = 1$. Let $P = (x_0, y_0, 0)$ be one such point. To find the tangent plane of the first equation at P , we will write it as $F(x, y, z) = x^2 + y^2 + z^2 - 1 = 0$. Now we find the partial derivatives of F and their values at the point P .

$$\begin{aligned}F_x(x, y, z) &= 2x & F_x(x_0, y_0, 0) &= 2x_0 \\ F_y(x, y, z) &= 2y & F_y(x_0, y_0, 0) &= 2y_0 \\ F_z(x, y, z) &= 2z & F_z(x_0, y_0, 0) &= 0\end{aligned}$$

The equation of the tangent plane at (x_0, y_0) is then

$$\begin{aligned}2x_0(x - x_0) + 2y_0(y - y_0) &= 0 \\ x_0x + y_0y &= x_0^2 + y_0^2 = 1.\end{aligned}$$

To find the tangent plane of the second equation at P , we will write it as $G(x, y, z) = x^2 + y^2 - z^2 - 1 = 0$. Now we find the partial derivatives of F and their values at the point P .

$$\begin{aligned}G_x(x, y, z) &= 2x & G_x(x_0, y_0, 0) &= 2x_0 \\ G_y(x, y, z) &= 2y & G_y(x_0, y_0, 0) &= 2y_0 \\ G_z(x, y, z) &= -2z & G_z(x_0, y_0, 0) &= 0\end{aligned}$$

The equation of the tangent plane is then

$$\begin{aligned}2x_0(x - x_0) + 2y_0(y - y_0) &= 0 \\ x_0x + y_0y &= x_0^2 + y_0^2 = 1\end{aligned}$$

Both tangent planes are the same at P , so the two surfaces are tangent at any point of intersection.

(b)

34. (a) If the two surfaces are orthogonal, then their normal lines are orthogonal, which means their gradient vectors are orthogonal. We will show that the gradient vectors to both surfaces at any point of intersection are orthogonal.

To find the points of intersection, we solve for $x^2 + y^2$ in the first equation and plug it into the second. Then

$$\begin{aligned}(4 - z^2) - z^2 &= 0 \\ z^2 &= 2 \\ z &= \pm\sqrt{2}.\end{aligned}$$

This means the two surfaces intersect in the planes $z = \pm\sqrt{2}$ when $x^2 + y^2 = 2$. Let $P = (x_0, y_0, z_0)$ be such a point; that is $x_0^2 + y_0^2 = 2$ and $z_0^2 = 2$. We start by writing the first equation as $F(x, y, z) = x^2 + y^2 + z^2 - 4 = 0$ and find its gradient.

$$\begin{aligned}\nabla F(x, y, z) &= 2x\mathbf{i} + 2y\mathbf{j} + 2z\mathbf{k} \\ \nabla F(x_0, y_0, z_0) &= 2x_0\mathbf{i} + 2y_0\mathbf{j} + 2z_0\mathbf{k}\end{aligned}$$

If we denote the second equation as $G(x, y, z) = x^2 + y^2 - z^2 = 0$, then

$$\begin{aligned}\nabla G(x, y, z) &= 2x\mathbf{i} + 2y\mathbf{j} - 2z\mathbf{k} \\ \nabla G(x_0, y_0, z_0) &= 2x_0\mathbf{i} + 2y_0\mathbf{j} - 2z_0\mathbf{k}.\end{aligned}$$

Now computing the dot product to show the two gradient vectors are orthogonal, we have

$$\begin{aligned}\nabla F(x_0, y_0, z_0) \cdot \nabla G(x_0, y_0, z_0) &= (2x_0\mathbf{i} + 2y_0\mathbf{j} + 2z_0\mathbf{k}) \cdot (2x_0\mathbf{i} + 2y_0\mathbf{j} - 2z_0\mathbf{k}) \\ &= 4(x_0^2 + y_0^2) - 4z_0^2 = 4(2) - 4(2) \\ &= 0.\end{aligned}$$

(b)

35. Denoting the sphere by $F(x, y, z) = x^2 + y^2 + z^2 - R^2 = 0$, the partial derivatives at a general point $P = (x_0, y_0, z_0)$ on the sphere are

$$\begin{aligned}F_x(x_0, y_0, z_0) &= 2x_0 \\ F_y(x_0, y_0, z_0) &= 2y_0 \\ F_z(x_0, y_0, z_0) &= 2z_0.\end{aligned}$$

Then symmetric equations of the normal line are

$$\frac{x - x_0}{2x_0} = \frac{y - y_0}{2y_0} = \frac{z - z_0}{2z_0}.$$

Notice if we plug in the origin $(0, 0, 0)$ to these equations, each fraction simplifies to $-\frac{1}{2}$ (since x_0, y_0, z_0 are all not equal to 0 so they can be cancelled), which means the normal line passes through the origin.

36. From Problem 35, we found the symmetric equations of the normal line to be

$$\frac{x - x_0}{2x_0} = \frac{y - y_0}{2y_0} = \frac{z - z_0}{2z_0}.$$

Plugging in the point $(-x_0, -y_0, -z_0)$ results in each fraction simplifying to -1 , which means the normal line passes through this point.

37. Denote the equation by $F(x, y, z) = \sin(x + y) + \sin(y + z) - 1 = 0$. Now we find the partial derivatives of F and their values at the point $(0, \frac{\pi}{2}, \frac{\pi}{2})$.

$$\begin{aligned} F_x(x, y, z) &= \cos(x + y) & F_x\left(0, \frac{\pi}{2}, \frac{\pi}{2}\right) &= 0 \\ F_y(x, y, z) &= \cos(x + y) + \cos(y + z) & F_y\left(0, \frac{\pi}{2}, \frac{\pi}{2}\right) &= -1 \\ F_z(x, y, z) &= \cos(y + z) & F_z\left(0, \frac{\pi}{2}, \frac{\pi}{2}\right) &= -1 \end{aligned}$$

Then an equation of the tangent plane is

$$0(x - 0) - 1\left(y - \frac{\pi}{2}\right) - \left(z - \frac{\pi}{2}\right) = 0$$

$y + z = \pi.$

Symmetric equations of the normal line are

$\frac{y - \frac{\pi}{2}}{-1} = \frac{z - \frac{\pi}{2}}{-1}; x = 0.$

38. To be parallel to the plane $2x - 3y + z = 4$ at the point $P = (x_0, y_0, z_0)$ means the normal line at P is parallel to the vector $\mathbf{u} = 2\mathbf{i} - 3\mathbf{j} + \mathbf{k}$. The normal line at P has direction $\nabla F(x_0, y_0, z_0)$ where $F(x, y, z) = \frac{x^2}{9} + \frac{y^2}{4} + \frac{z^2}{36} - 1 = 0$. Then

$$\nabla F(x, y, z) = \frac{2}{9}x\mathbf{i} + \frac{1}{2}y\mathbf{j} + \frac{1}{18}z\mathbf{k},$$

So if the normal line at P is parallel to $\mathbf{u}$, then $\nabla F(x_0, y_0, z_0) = c\mathbf{u}$ for some constant c , or

$$\frac{2}{9}x_0 = 2c \quad \frac{1}{2}y_0 = -3c \quad \frac{1}{18}z_0 = c.$$

Solving the first equation for c and plugging it into the second, we have $y_0 = -\frac{2}{3}x_0$. Similarly plugging it into the third equation, we have $z_0 = 2x_0$. If this point must be on the given surface, then

$$\begin{aligned} \frac{x_0^2}{9} + \frac{\left(-\frac{2}{3}x_0\right)^2}{4} + \frac{(2x_0)^2}{36} &= 1 \\ \frac{x_0^2}{3} &= 1 \\ x_0 &= \pm\sqrt{3}. \end{aligned}$$

This means there are two points where the tangent plane is parallel to the plane $2x - 3y + z = 4$, and they

are $\left(\sqrt{3}, -\frac{2}{3}\sqrt{3}, 2\sqrt{3}\right)$ and $\left(-\sqrt{3}, \frac{2}{3}\sqrt{3}, -2\sqrt{3}\right)$.

39. The cylinder can be written as $F(x, y, z) = x^2 + y^2 - a^2 = 0$. Then

$$\begin{aligned} F_x(x, y, z) &= 2x & F_x(x_0, y_0, z_0) &= 2x_0 \\ F_y(x, y, z) &= 2y & F_y(x_0, y_0, z_0) &= 2y_0 \\ F_z(x, y, z) &= 0 & F_z(x_0, y_0, z_0) &= 0 \end{aligned}$$

Then an equation of the tangent plane is

$$2x_0(x - x_0) + 2y_0(y - y_0) + 0(z - z_0) = 0$$

$$\boxed{x_0x + y_0y = x_0^2 + y_0^2 = a^2}.$$

40. The cone can be written as $F(x, y, z) = \frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0$. Then

$$\begin{aligned} F_x(x, y, z) &= \frac{2x}{a^2} & F_x(x_0, y_0, z_0) &= \frac{2x_0}{a^2} \\ F_y(x, y, z) &= \frac{2y}{b^2} & F_y(x_0, y_0, z_0) &= \frac{2y_0}{b^2} \\ F_z(x, y, z) &= -\frac{2z}{c^2} & F_z(x_0, y_0, z_0) &= -\frac{2z_0}{c^2} \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} \frac{2x_0}{a^2}(x - x_0) + \frac{2y_0}{b^2}(y - y_0) - \frac{2z_0}{c^2}(z - z_0) &= 0 \\ \frac{x_0}{a^2}x + \frac{y_0}{b^2}y - \frac{z_0}{c^2}z &= \frac{x_0^2}{a^2} + \frac{y_0^2}{b^2} - \frac{z_0^2}{c^2} = 0 \\ \boxed{\frac{x_0}{a^2}x + \frac{y_0}{b^2}y &= \frac{z_0}{c^2}z}. \end{aligned}$$

The point $(0, 0, 0)$ needs to be treated separately because at this point all the partial derivatives vanish.

41. We begin by finding the partial derivatives of $F(x, y, z) = x^{1/2} + y^{1/2} + z^{1/2} - a^{1/2} = 0$ and their values at a general point (x_0, y_0, z_0) .

$$\begin{aligned} F_x(x, y, z) &= \frac{1}{2}x^{-1/2} & F_x(x_0, y_0, z_0) &= \frac{1}{2\sqrt{x_0}} \\ F_y(x, y, z) &= \frac{1}{2}y^{-1/2} & F_y(x_0, y_0, z_0) &= \frac{1}{2\sqrt{y_0}} \\ F_z(x, y, z) &= \frac{1}{2}z^{-1/2} & F_z(x_0, y_0, z_0) &= \frac{1}{2\sqrt{z_0}} \end{aligned}$$

Then an equation of the tangent plane is

$$\begin{aligned} \frac{1}{2\sqrt{x_0}}(x - x_0) + \frac{1}{2\sqrt{y_0}}(y - y_0) + \frac{1}{2\sqrt{z_0}}(z - z_0) &= 0 \\ \frac{1}{\sqrt{x_0}}(x - x_0) + \frac{1}{\sqrt{y_0}}(y - y_0) + \frac{1}{\sqrt{z_0}}(z - z_0) &= 0. \end{aligned}$$

The intercept on the x -axis is the point where $y = z = 0$, so plugging $y = z = 0$ into the tangent plane, we find that

$$\begin{aligned} \frac{1}{\sqrt{x_0}}(x - x_0) - \frac{y_0}{\sqrt{y_0}} - \frac{z_0}{\sqrt{z_0}} &= 0 \\ \frac{x}{\sqrt{x_0}} &= \frac{x_0}{\sqrt{x_0}} + \frac{y_0}{\sqrt{y_0}} + \frac{z_0}{\sqrt{z_0}} \\ \frac{x}{\sqrt{x_0}} &= x_0^{1/2} + y_0^{1/2} + z_0^{1/2} = a^{1/2}. \end{aligned}$$

So the x -intercept is $a^{1/2}\sqrt{x_0}$. Similarly, the y - and z -intercepts are $a^{1/2}\sqrt{y_0}$ and $a^{1/2}\sqrt{z_0}$, respectively. If we add the three intercepts together, we get

$$a^{1/2}\sqrt{x_0} + a^{1/2}\sqrt{y_0} + a^{1/2}\sqrt{z_0} = a^{1/2}(x_0^{1/2} + y_0^{1/2} + z_0^{1/2}) = a^{1/2}a^{1/2} = a,$$

which is a constant.

Challenge Problems

42. Let $F(x, y, z) = x \sin(yz) - 1 = 0$ and $G(x, y, z) = ze^{y^2-x^2} - \frac{\pi}{2} = 0$. The tangent line at $\left(1, 1, \frac{\pi}{2}\right)$ is perpendicular to both $\nabla F\left(1, 1, \frac{\pi}{2}\right)$ and $\nabla G\left(1, 1, \frac{\pi}{2}\right)$. One vector $\mathbf{v}$ that is perpendicular to both gradient vectors is the cross product

$$\mathbf{v} = \nabla F\left(1, 1, \frac{\pi}{2}\right) \times \nabla G\left(1, 1, \frac{\pi}{2}\right).$$

We now compute the two gradient vectors.

$$\begin{aligned} F_x(x, y, z) &= \sin(yz) & F_x\left(1, 1, \frac{\pi}{2}\right) &= 1 \\ F_y(x, y, z) &= xz \cos(yz) & F_y\left(1, 1, \frac{\pi}{2}\right) &= 0 \\ F_z(x, y, z) &= xy \cos(yz) & F_z\left(1, 1, \frac{\pi}{2}\right) &= 0, \end{aligned}$$

so $\nabla F\left(1, 1, \frac{\pi}{2}\right) = \mathbf{i}$. Also,

$$\begin{aligned} G_x(x, y, z) &= -2xze^{y^2-x^2} & G_x\left(1, 1, \frac{\pi}{2}\right) &= -\pi \\ G_y(x, y, z) &= 2yze^{y^2-x^2} & G_y\left(1, 1, \frac{\pi}{2}\right) &= \pi \\ G_z(x, y, z) &= e^{y^2-x^2} & G_z\left(1, 1, \frac{\pi}{2}\right) &= 1, \end{aligned}$$

so $\nabla G\left(1, 1, \frac{\pi}{2}\right) = -\pi\mathbf{i} + \pi\mathbf{j} + \mathbf{k}$. Then

$$\mathbf{v} = \nabla F\left(1, 1, \frac{\pi}{2}\right) \times \nabla G\left(1, 1, \frac{\pi}{2}\right) = -\mathbf{j} + \pi\mathbf{k}.$$

This means an equation of the tangent line is

$$\boxed{\mathbf{r}(t) = \left(\mathbf{i} + \mathbf{j} + \frac{\pi}{2}\mathbf{k}\right) + t\mathbf{v} = \left(\mathbf{i} + \mathbf{j} + \frac{\pi}{2}\mathbf{k}\right) + t(-\mathbf{j} + \pi\mathbf{k}).}$$

43. Let $F(x, y, z) = (yz)^{xz}$. To find the partial derivatives of F , we will use logarithmic differentiation. Take the natural log of F , so

$$\ln F(x, y, z) = \ln((yz)^{xz}) = xz \ln(yz). \quad (13.1)$$

Now differentiate both sides of (13.1) with respect to x .

$$\begin{aligned} \frac{1}{F(x, y, z)} \cdot F_x(x, y, z) &= z \ln(yz) \\ F_x(x, y, z) &= (yz)^{xz} \cdot z \ln(yz) \end{aligned}$$

Differentiate both sides of (13.1) with respect to y .

$$\begin{aligned} \frac{1}{F(x, y, z)} \cdot F_y(x, y, z) &= xz \cdot \frac{z}{yz} = \frac{xz}{y} \\ F_y(x, y, z) &= (yz)^{xz} \cdot \frac{xz}{y} \end{aligned}$$

Differentiate both sides of (13.1) with respect to z .

$$\begin{aligned} \frac{1}{F(x, y, z)} \cdot F_z(x, y, z) &= x \ln(yz) + xz \cdot \frac{y}{yz} = x \ln(yz) + x \\ F_z(x, y, z) &= (yz)^{xz} (x \ln(yz) + x) \end{aligned}$$

If we plug in the point $(2, 1, 2)$ to each of the partial derivatives, we have

$$\begin{aligned} F_x(2, 1, 2) &= 32 \ln(2) \\ F_y(2, 1, 2) &= 64 \\ F_z(2, 1, 2) &= 32 \ln(2) + 32. \end{aligned}$$

Then an equation of the tangent plane is

$$32 \ln(2)(x - 2) + 64(y - 1) + (32 \ln(2) + 32)(z - 2) = 0$$

$$\boxed{\ln(2)x + 2y + (\ln(2) + 1)z = 4 + 4 \ln(2)}.$$

Symmetric equations of the normal line are

$$\boxed{\frac{x - 2}{\ln(2)} = \frac{y - 1}{2} = \frac{z - 2}{\ln(2) + 1}}.$$

44. No, the two vectors do not necessarily have to be at right angles. For example, take $f(x, y) = x^2 + y^2$ and write the equation of the tangent plane at $\left(\frac{1}{2}, \frac{1}{2}\right)$. The partial derivatives are $f_x(x, y) = 2x$ and $f_y(x, y) = 2y$, so an equation of the tangent plane is

$$\begin{aligned} \left(x - \frac{1}{2}\right) + \left(y - \frac{1}{2}\right) &= z - \frac{1}{2} \\ x + y - z &= \frac{1}{2}. \end{aligned}$$

The two vectors $\mathbf{v}_1 = \mathbf{i} + \mathbf{k}$ and $\mathbf{v}_2 = \mathbf{j} + \mathbf{k}$ both lie in the tangent plane since they are orthogonal to the normal vector $\mathbf{i} + \mathbf{j} - \mathbf{k}$. However $\mathbf{v}_1$ and $\mathbf{v}_2$ are not at a right angle since $\mathbf{v}_1 \cdot \mathbf{v}_2 \neq 0$.

13.3 Extrema of Functions of Two Variables

Concepts and Vocabulary

1. Suppose $z = f(x, y)$ is a function with domain D , and (x_0, y_0) is an interior point of D . If $f(x_0, y_0) \geq f(x, y)$ for all points (x, y) within some disk centered at (x_0, y_0) , then f has **(a) a local maximum** at (x_0, y_0) .
2. If $z = f(x, y)$ is a function of two variables whose domain is an open set D containing the point (x_0, y_0) , then the point (x_0, y_0) is a critical point of f if $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$ or if $f_x(x_0, y_0)$ or $f_y(x_0, y_0)$ does not exist.
3. **False**. See the theorem preceding Example 1.
4. If $f_x(x_0, y_0) = 0$ and $f_y(x_0, y_0) = 0$, but f does not have a local extremum at (x_0, y_0) , then the point $(x_0, y_0, f(x_0, y_0))$ is called **(c) a saddle point**.
5. **True**. See the theorem in subsection 3.
6. If $z = f(x, y)$ is a function of two variables that is continuous on a closed, bounded set D , then the absolute extrema are either at the critical points of f in D or on the **boundary** of D .

Skill Building

7. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 4x^3 - 4x = 0 \\ f_y(x, y) = 2y = 0 \end{cases}$$

From f_y , we see that $y = 0$ and f_x factors as $4x(x^2 - 1) = 0$ so the critical points are $(0, 0), (1, 0), (-1, 0)$.

8. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x + 6 = 0 \\ f_y(x, y) = -2y - 2 = 0 \end{cases}$$

The only critical point is $(-3, -1)$.

9. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 4y - 4x^3 = 0 \\ f_y(x, y) = 4x - 4y^3 = 0 \end{cases}$$

From the first equation, $y = x^3$ and plugging it into the f_y equation, we have

$$\begin{aligned} 4x - 4(x^3)^3 &= 0 \\ x(1 - x^8) &= 0 \\ x &= 0, \pm 1. \end{aligned}$$

This means the critical points are $(0, 0), (1, 1), (-1, -1)$.

10. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3x^2 + 6y = 0 \\ f_y(x, y) = 6x + 6y = 0 \end{cases}$$

From the second equation, $x = -y$ and plugging it into the f_x equation, we have

$$\begin{aligned} 3(-y)^2 + 6y &= 0 \\ 3y(y + 2) &= 0 \\ y &= 0, -2. \end{aligned}$$

This means the critical points are $(0, 0), (2, -2)$.

11. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = -e^{-x}(x^2 + y) + 2xe^{-x} = 0 \\ f_y(x, y) = e^{-x} = 0 \end{cases}$$

Since e^{-x} is never equal to 0, there are no solutions to the bottom equation, which means there are no critical points.

12. First we find the partial derivatives.

$$\begin{cases} f_x(x, y) = y - \frac{2}{x^2} = 0 \\ f_y(x, y) = x - \frac{4}{y^2} = 0 \end{cases}$$

Notice that neither f_x nor f_y are defined when $x = 0$ or $y = 0$, however these values are not in the domain of f , so the only critical points come from solving the system above. Solving for y in the f_x equation and plugging it into the f_y equation, we have

$$\begin{aligned} x - \frac{4}{(2/x^2)^2} &= 0 \\ x - x^4 = x(1 - x^3) &= 0 \\ x &= 1, \end{aligned}$$

where we excluded the solution $x = 0$ since any point with x -coordinate 0 is not in the domain of f . This means the only critical point is (1, 2).

13. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 2 = 0 \\ f_y(x, y) = 2y + 4 = 0 \end{cases}$$

The only solution is $x = 1, y = -2$, so the only critical point is $(1, -2)$. The second-order partial derivatives and their values at $(1, -2)$ are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 2 & A &= f_{xx}(1, -2) = 2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & B &= f_{xy}(1, -2) = 0 \\ f_{yy}(x, y) &= 2 & C &= f_{yy}(1, -2) = 2 \\ AC - B^2 &= 4 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$, $(1, -2)$ is a local minimum. The local minimum is at (1, -2) and the local minimum is $z = -3$.

14. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 4 = 0 \\ f_y(x, y) = 2y + 2 = 0 \end{cases}$$

The only solution is $x = 2, y = -1$, so the only critical point is $(2, -1)$. The second-order partial derivatives and their values at $(2, -1)$ are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 2 & A &= f_{xx}(2, -1) = 2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & B &= f_{xy}(2, -1) = 0 \\ f_{yy}(x, y) &= 2 & C &= f_{yy}(2, -1) = 2 \\ AC - B^2 &= 4 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$, $(2, -1)$ is a local minimum. The local minimum is at (2, -1) and the local minimum is $z = -9$.

15. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 4 = 0 \\ f_y(x, y) = 8y + 8 = 0 \end{cases}$$

The only solution is $x = 2, y = -1$, so the only critical point is $(2, -1)$. The second-order partial derivatives and their values at $(2, -1)$ are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 2 & A &= f_{xx}(2, -1) = 2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & B &= f_{xy}(2, -1) = 0 \\ f_{yy}(x, y) &= 8 & C &= f_{yy}(2, -1) = 8 \\ AC - B^2 &= 16 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$, $(2, -1)$ is a local minimum. The local minimum is at $(2, -1)$ and the local minimum is $z = -9$.

16. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 4x + 4 = 0 \\ f_y(x, y) = -2y - 4 = 0 \end{cases}$$

The only solution is $x = -1, y = -2$, so the only critical point is $(-1, -2)$. The second-order partial derivatives and their values at $(-1, -2)$ are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 4 & A &= f_{xx}(-1, -2) = 4 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & B &= f_{xy}(-1, -2) = 0 \\ f_{yy}(x, y) &= -2 & C &= f_{yy}(-1, -2) = -2 \\ AC - B^2 &= -8 \end{aligned}$$

Since $AC - B^2 < 0$, $(-1, -2, 10)$ is a saddle point.

17. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3x^2 - 6y = 0 \\ f_y(x, y) = -6x + 3y^2 = 0 \end{cases}$$

Solving for y in the f_x equation and substituting it into the f_y equation, we have

$$\begin{aligned} -6x + 3\left(\frac{1}{2}x^2\right)^2 &= 0 \\ -24x + 3x^4 &= 3x(-8 + x^3) = 0 \\ x &= 0, 2. \end{aligned}$$

The two critical points are then $(0, 0), (2, 2)$. The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 6x & f_{xx}(0, 0) &= 0 & f_{xx}(2, 2) &= 12 \\ f_{xy}(x, y) &= f_{yx}(x, y) = -6 & f_{xy}(0, 0) &= -6 & f_{xy}(2, 2) &= -6 \\ f_{yy}(x, y) &= 6y & f_{yy}(0, 0) &= 0 & f_{yy}(2, 2) &= 12 \end{aligned}$$

For the critical point $(0, 0)$, $f_{xx}(0, 0) \cdot f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = -36 < 0$, so $(0, 0, 0)$ is a saddle point.

For the critical point $(2, 2)$, $f_{xx}(2, 2) \cdot f_{yy}(2, 2) - [f_{xy}(2, 2)]^2 = 108 > 0$ and $f_{xx}(2, 2) > 0$, so $(2, 2)$ is a local minimum. The local minimum is at $(2, 2)$ and the local minimum is $z = -8$.

18. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 3y = 0 \\ f_y(x, y) = -3x - 2y = 0 \end{cases}$$

The only solution to this system is $(0, 0)$. The second-order partial derivatives and their values at the critical point are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 2 & A &= f_{xx}(0, 0) = 2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = -3 & B &= f_{xy}(0, 0) = -3 \\ f_{yy}(x, y) &= -2 & C &= f_{yy}(0, 0) = -2 \\ AC - B^2 &= -13 \end{aligned}$$

Since $AC - B^2 < 0$, $\boxed{(0, 0, 0) \text{ is a saddle point}}$.

19. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x + 3y - 6 = 0 \\ f_y(x, y) = 3x - 2y + 4 = 0 \end{cases}$$

Solving for x in f_x and plugging it into f_y , we have

$$\begin{aligned} 3\left(\frac{6-3y}{2}\right) - 2y + 4 &= 0 \\ 18 - 9y - 4y &= -8 \\ y &= 2. \end{aligned}$$

The only critical point is then $(0, 2)$. The second-order partial derivatives and their values at the critical point are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 2 & A &= f_{xx}(0, 2) = 2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 3 & B &= f_{xy}(0, 2) = 3 \\ f_{yy}(x, y) &= -2 & C &= f_{yy}(0, 2) = -2 \\ AC - B^2 &= -13 \end{aligned}$$

Since $AC - B^2 < 0$, $\boxed{(0, 2, 4) \text{ is a saddle point}}$.

20. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 4x + y - 2 = 0 \\ f_y(x, y) = x + 2y + 3 = 0 \end{cases}$$

Solving for y in f_x and plugging it into f_y , we have

$$\begin{aligned} x + 2(2 - 4x) + 3 &= 0 \\ -7x + 7 &= 0 \\ x &= 1. \end{aligned}$$

The only critical point is then $(1, -2)$. The second-order partial derivatives and their values at the critical point are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 4 & A &= f_{xx}(1, -2) = 4 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 1 & B &= f_{xy}(1, -2) = 1 \\ f_{yy}(x, y) &= 2 & C &= f_{yy}(1, -2) = 2 \\ AC - B^2 &= 7 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$, the critical point $(1, -2)$ is a local minimum. The local minimum is at $\boxed{(1, -2)}$ and the local minimum is $\boxed{z = 2}$.

21. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3x^2 + 3y = 0 \\ f_y(x, y) = 3x + 3y^2 = 0 \end{cases}$$

Solving for y in f_x and plugging it into f_y , we have

$$\begin{aligned} 3x + 3(-x^2)^2 &= 0 \\ x(1 + x^3) &= 0 \\ x &= 0, -1. \end{aligned}$$

The two critical points are then $(0, 0)$ and $(-1, -1)$. The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 6x & f_{xx}(0, 0) &= 0 & f_{xx}(-1, -1) &= -6 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 3 & f_{xy}(0, 0) &= 3 & f_{xy}(-1, -1) &= 3 \\ f_{yy}(x, y) &= 6y & f_{yy}(0, 0) &= 0 & f_{yy}(-1, -1) &= -6 \end{aligned}$$

For the critical point $(0, 0)$, $f_{xx}(0, 0) \cdot f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = -9 < 0$, so $(0, 0, 0)$ is a saddle point.

For the critical point $(-1, -1)$, $f_{xx}(-1, -1) \cdot f_{yy}(-1, -1) - [f_{xy}(-1, -1)]^2 = 27 > 0$ and $f_{xx}(-1, -1) < 0$, so $(-1, -1)$ is a local maximum. The local maximum is at $(-1, -1)$ and the local maximum is $z = 1$.

22. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3x^2 - 3y = 0 \\ f_y(x, y) = -3x - 3y^2 = 0 \end{cases}$$

Solving for y in f_x and plugging it into f_y , we have

$$\begin{aligned} -3x - 3(x^2)^2 &= 0 \\ x(1 + x^3) &= 0 \\ x &= 0, -1. \end{aligned}$$

The two critical points are then $(0, 0)$ and $(-1, 1)$. The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 6x & f_{xx}(0, 0) &= 0 & f_{xx}(-1, 1) &= -6 \\ f_{xy}(x, y) &= f_{yx}(x, y) = -3 & f_{xy}(0, 0) &= -3 & f_{xy}(-1, 1) &= -3 \\ f_{yy}(x, y) &= -6y & f_{yy}(0, 0) &= 0 & f_{yy}(-1, 1) &= -6 \end{aligned}$$

For the critical point $(0, 0)$, $f_{xx}(0, 0) \cdot f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = 9 < 0$, so $(0, 0, 0)$ is a saddle point.

For the critical point $(-1, 1)$, $f_{xx}(-1, 1) \cdot f_{yy}(-1, 1) - [f_{xy}(-1, 1)]^2 = 27 > 0$ and $f_{xx}(-1, 1) < 0$, so $(-1, 1)$ is a local maximum. The local maximum is at $(-1, 1)$ and the local maximum is $z = 1$.

23. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3x^2 + 2xy = 0 \\ f_y(x, y) = x^2 + 2y = 0 \end{cases}$$

Solving for y in f_y and plugging it into f_x , we have

$$\begin{aligned} 3x^2 + 2x\left(-\frac{x^2}{2}\right) &= 0 \\ x^2(3 - x) &= 0 \\ x &= 0, 3. \end{aligned}$$

The two critical points are then $(0, 0)$ and $\left(3, -\frac{9}{2}\right)$. The second-order partial derivatives and their values

at the critical points are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 6x + 2y & f_{xx}(0, 0) &= 0 & f_{xx}\left(3, -\frac{9}{2}\right) &= 9 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 2x & f_{xy}(0, 0) &= 0 & f_{xy}\left(3, -\frac{9}{2}\right) &= 6 \\ f_{yy}(x, y) &= 2 & f_{yy}(0, 0) &= 2 & f_{yy}\left(3, -\frac{9}{2}\right) &= 2 \end{aligned}$$

For the critical point $(0, 0)$, $f_{xx}(0, 0) \cdot f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = 0$, so the

second partial derivative test is inconclusive for the point $(0, 0)$

For the critical point $\left(3, -\frac{9}{2}\right)$, $f_{xx}\left(3, -\frac{9}{2}\right) \cdot f_{yy}\left(3, -\frac{9}{2}\right) - [f_{xy}\left(3, -\frac{9}{2}\right)]^2 = -18 < 0$, so

$\left(3, -\frac{9}{2}, \frac{27}{4}\right)$ is a saddle point.

24. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = -2xy + 1 = 0 \\ f_y(x, y) = 9y^2 - x^2 = 0 \end{cases}$$

Note that neither x nor y can be equal to 0 (because of the first equation) so solving for y in f_x and plugging it into f_y , we have

$$\begin{aligned} 9\left(\frac{1}{2x}\right)^2 - x^2 &= 0 \\ \frac{9}{4x^2} - x^2 &= 0 \\ \frac{9}{4} - x^4 &= 0 \\ x &= \pm \sqrt[4]{\frac{9}{4}} = \pm \sqrt{\frac{3}{2}} = \pm \frac{\sqrt{6}}{2}. \end{aligned}$$

Since $y = \frac{1}{2x}$ the two critical points are then $\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right)$ and $\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right)$. The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{aligned} f_{xx}(x, y) &= -2y & f_{xx}\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right) &= -\frac{\sqrt{6}}{3} & f_{xx}\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right) &= \frac{\sqrt{6}}{3} \\ f_{xy}(x, y) &= f_{yx}(x, y) = -2x & f_{xy}\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right) &= -\sqrt{6} & f_{xy}\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right) &= \sqrt{6} \\ f_{yy}(x, y) &= 18y & f_{yy}\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right) &= 3\sqrt{6} & f_{yy}\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right) &= -3\sqrt{6} \end{aligned}$$

For the critical point $\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right)$,

$$f_{xx}\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right) \cdot f_{yy}\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right) - [f_{xy}\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}\right)]^2 = -12 < 0,$$

so $\left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{6}, \frac{\sqrt{6}}{3}\right)$ is a saddle point.

For the critical point $\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right)$, $f_{xx}\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right) \cdot f_{yy}\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right) - \left[f_{xy}\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}\right)\right]^2 = -12 < 0$, so $\left(-\frac{\sqrt{6}}{2}, -\frac{\sqrt{6}}{6}, -\frac{\sqrt{6}}{3}\right)$ is a saddle point.

25. The partial derivatives are

$$\begin{aligned} f_x(x, y) &= \frac{(x+y)(0) - (y)(1)}{(x+y)^2} = -\frac{y}{(x+y)^2} \\ f_y(x, y) &= \frac{(x+y)(1) - (y)(1)}{(x+y)^2} = \frac{x}{(x+y)^2}. \end{aligned}$$

The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = -\frac{y}{(x+y)^2} = 0 \\ f_y(x, y) = \frac{x}{(x+y)^2} = 0 \end{cases}$$

or where f_x or f_y are undefined. However, all points where f_x or f_y are undefined are not in the domain of f , so we need only find solutions of the system to find critical points. The only solution is $x = 0, y = 0$, but this point is not in the domain, so there are no critical points.

26. The partial derivatives are

$$\begin{aligned} f_x(x, y) &= \frac{(x+y)(1) - (x)(1)}{(x+y)^2} = \frac{y}{(x+y)^2} \\ f_y(x, y) &= \frac{(x+y)(0) - (x)(1)}{(x+y)^2} = -\frac{x}{(x+y)^2}. \end{aligned}$$

The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = \frac{y}{(x+y)^2} = 0 \\ f_y(x, y) = -\frac{x}{(x+y)^2} = 0 \end{cases}$$

or where f_x or f_y are undefined. However, all points where f_x or f_y are undefined are not in the domain of f , so we need only find solutions of the system to find critical points. The only solution is $x = 0, y = 0$, but this point is not in the domain, so there are no critical points.

27. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = -\sin x = 0 \\ f_y(x, y) = -\sin y = 0 \end{cases}$$

The critical points are then $(m\pi, n\pi)$ for any integers m, n . The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{array}{lll} f_{xx}(x, y) = -\cos x & f_{xx}(m\pi, n\pi) = 1 \text{ if } m \text{ is odd} & f_{xx}(m\pi, n\pi) = -1 \text{ if } m \text{ is even} \\ f_{xy}(x, y) = f_{yx}(x, y) = 0 & & f_{xy}(m\pi, n\pi) = 0 \\ f_{yy}(x, y) = -\cos y & f_{yy}(m\pi, n\pi) = 1 \text{ if } n \text{ is odd} & f_{yy}(m\pi, n\pi) = -1 \text{ if } n \text{ is even} \end{array}$$

If m and n are odd, then $f_{xx}(m\pi, n\pi) \cdot f_{yy}(m\pi, n\pi) - (f_{xy}(m\pi, n\pi))^2 = 1 > 0$ and $f_{xx}(m\pi, n\pi) > 0$ so $(m\pi, n\pi)$ is a local minimum. The local minimum is at $(m\pi, n\pi)$ for m and n odd and the local minimum is $z = -2$

If m and n are even, then $f_{xx}(m\pi, n\pi) \cdot f_{yy}(m\pi, n\pi) - (f_{xy}(m\pi, n\pi))^2 = 1 > 0$ and $f_{xx}(m\pi, n\pi) < 0$ so $(m\pi, n\pi)$ is a local maximum. The local maximum is at $(m\pi, n\pi)$ for m and n even and the local maximum is $z = 2$.

If exactly one of m or n is odd and the other is even, then

$f_{xx}(m\pi, n\pi) \cdot f_{yy}(m\pi, n\pi) - (f_{xy}(m\pi, n\pi))^2 = -1 < 0$, so $(m\pi, n\pi, 0)$ is a saddle point when exactly one of m or n is odd.

28. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 4 \cos y = 0 \\ f_y(x, y) = 4x \sin y = 0 \end{cases}$$

From the second equation, we see that $x = 0$ or $y = n\pi$ for some integer n . If $x = 0$, then the first equation tells us that $y = m\pi + \frac{\pi}{2}$ for some integer m .

If $y = n\pi$, then the first equation tells us that $x = 2$ when n is even and $x = -2$ when n is odd. So the critical points are

$$\begin{aligned} \text{Case 1 : } & \left(0, m\pi + \frac{\pi}{2}\right) \quad \text{for } m \text{ an integer} \\ \text{Case 2 : } & (2, n\pi) \quad \text{for } n \text{ an even integer} \\ \text{Case 3 : } & (-2, n\pi) \quad \text{for } n \text{ an odd integer.} \end{aligned}$$

The second-order partial derivatives are

$$f_{xx}(x, y) = 2 \quad f_{xy}(x, y) = f_{yx}(x, y) = 4 \sin y \quad f_{yy}(x, y) = 4x \cos y.$$

In Case 1, $f_{xx}\left(0, m\pi + \frac{\pi}{2}\right) \cdot f_{yy}\left(0, m\pi + \frac{\pi}{2}\right) - [f_{xy}\left(0, m\pi + \frac{\pi}{2}\right)]^2 = -16 < 0$ so the points

$\left(0, m\pi + \frac{\pi}{2}, 4\right)$ are saddle points.

In Case 2, $f_{xx}(2, n\pi) \cdot f_{yy}(2, n\pi) - [f_{xy}(2, n\pi)]^2 = 16 > 0$ and $f_{xx}(2, n\pi) > 0$ so these points are local minimums. The local minima are at $(2, n\pi)$ for n an even integer and the local minima is $z = 0$.

In Case 3, $f_{xx}(-2, n\pi) \cdot f_{yy}(-2, n\pi) - [f_{xy}(-2, n\pi)]^2 = 16 > 0$ and $f_{xx}(-2, n\pi) > 0$ so these points are local minimums. The local minima are at $(-2, n\pi)$ for n an odd integer and the local minima is $z = 0$.

29. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 6y \sin x = 0 \\ f_y(x, y) = 2y - 6 \cos x = 0 \end{cases}$$

From the first equation, we see that $y = 0$ or $x = n\pi$ for some integer n . If $y = 0$, then the second equation tells us that $x = m\pi + \frac{\pi}{2}$ for some integer m .

If $x = n\pi$, then the second equation tells us that $y = 3$ when n is even and $y = -3$ when n is odd. So the critical points are

$$\begin{aligned} \text{Case 1 : } & \left(m\pi + \frac{\pi}{2}, 0\right) \quad \text{for } m \text{ an integer} \\ \text{Case 2 : } & (n\pi, 3) \quad \text{for } n \text{ an even integer} \\ \text{Case 3 : } & (n\pi, -3) \quad \text{for } n \text{ an odd integer.} \end{aligned}$$

The second-order partial derivatives are

$$f_{xx}(x, y) = 6y \cos x \quad f_{xy}(x, y) = f_{yx}(x, y) = 6 \sin x \quad f_{yy}(x, y) = 2.$$

In Case 1, $f_{xx}\left(m\pi + \frac{\pi}{2}, 0\right) \cdot f_{yy}\left(m\pi + \frac{\pi}{2}, 0\right) - [f_{xy}\left(m\pi + \frac{\pi}{2}, 0\right)]^2 = -36 < 0$ so the points

$\left(m\pi + \frac{\pi}{2}, 0, 6\right)$ are saddle points.

In Case 2, $f_{xx}(n\pi, 3) \cdot f_{yy}(n\pi, 3) - [f_{xy}(n\pi, 3)]^2 = 36 > 0$ and $f_{xx}(n\pi, 3) = 18 > 0$ so these points are local minimums. The local minima are at $(n\pi, 3)$ for n an even integer and the local minima is $z = -3$.

In Case 3, $f_{xx}(n\pi, -3) \cdot f_{yy}(n\pi, -3) - [f_{xy}(n\pi, -3)]^2 = 16 > 0$ and $f_{xx}(n\pi, -3) = 18 > 0$ so these points are local minimums. The local minima are at $(n\pi, -3)$ for n an odd integer and the local minima is $z = -3$.

30. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 6\sin y = 0 \\ f_y(x, y) = -6x\cos y = 0 \end{cases}$$

From the second equation, we see that $x = 0$ or $y = n\pi + \frac{\pi}{2}$ for some integer n . If $x = 0$, then the first equation tells us that $y = m\pi$ for some integer m .

If $y = n\pi + \frac{\pi}{2}$, then the first equation tells us that $x = 3$ when n is even and $x = -3$ when n is odd. So the critical points are

$$\begin{aligned} \text{Case 1 :} & \quad (0, m\pi) \quad \text{for } m \text{ an integer} \\ \text{Case 2 :} & \quad \left(3, n\pi + \frac{\pi}{2}\right) \quad \text{for } n \text{ an even integer} \\ \text{Case 3 :} & \quad \left(-3, n\pi + \frac{\pi}{2}\right) \quad \text{for } n \text{ an odd integer.} \end{aligned}$$

The second-order partial derivatives are

$$f_{xx}(x, y) = 2 \quad f_{xy}(x, y) = f_{yx}(x, y) = -6\cos y \quad f_{yy}(x, y) = 6x\sin y.$$

In Case 1, $f_{xx}(0, m\pi) \cdot f_{yy}(0, m\pi) - [f_{xy}(0, m\pi)]^2 = -36 < 0$ so the points $(0, m\pi, 2)$ are saddle points.

In Case 2, $f_{xx}\left(3, n\pi + \frac{\pi}{2}\right) \cdot f_{yy}\left(3, n\pi + \frac{\pi}{2}\right) - \left[f_{xy}\left(3, n\pi + \frac{\pi}{2}\right)\right]^2 = 36 > 0$ and $f_{xx}\left(3, n\pi + \frac{\pi}{2}\right) > 0$ so these points are local minimums. The local minima are at $\left(3, n\pi + \frac{\pi}{2}\right)$ for n an even integer and the local minima is $z = -7$.

In Case 3, $f_{xx}\left(-3, n\pi + \frac{\pi}{2}\right) \cdot f_{yy}\left(-3, n\pi + \frac{\pi}{2}\right) - \left[f_{xy}\left(-3, n\pi + \frac{\pi}{2}\right)\right]^2 = 36 > 0$ and $f_{xx}\left(-3, n\pi + \frac{\pi}{2}\right) > 0$ so these points are local minimums. The local minima are at $\left(-3, n\pi + \frac{\pi}{2}\right)$ for n an odd integer and the local minima is $z = -7$.

31. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = ye^{xy} = 0 \\ f_y(x, y) = xe^{xy} = 0 \end{cases}$$

Since e^{xy} is never equal to 0, the only critical point is $(0, 0)$. The second-order partial derivatives and their values at the critical point are as follows.

$$\begin{aligned} f_{xx}(x, y) &= y^2e^{xy} & A &= f_{xx}(0, 0) = 0 \\ f_{xy}(x, y) &= f_{yx}(x, y) = e^{xy} + xye^{xy} & B &= f_{xy}(0, 0) = 1 \\ f_{yy}(x, y) &= x^2e^{xy} & C &= f_{yy}(0, 0) = 0 \\ AC - B^2 &= -1 \end{aligned}$$

Since $AC - B^2 < 0$, $(0, 0, 1)$ is a saddle point.

32. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = ye^{-(x+y)} - xye^{-(x+y)} = 0 \\ f_y(x, y) = xe^{-(x+y)} - xye^{-(x+y)} = 0 \end{cases}$$

Since $e^{-(x+y)}$ is never equal to 0, we can cancel it and obtain the new system to solve.

$$\begin{cases} y - xy = y(1 - x) = 0 \\ x - xy = x(1 - y) = 0 \end{cases}$$

From here, we see the only critical points are $(0,0)$ and $(1,1)$. The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{array}{lll} f_{xx}(x,y) = -2ye^{-(x+y)} + xye^{-(x+y)} & f_{xx}(1,1) = -e^{-2} & f_{xx}(0,0) = 0 \\ f_{xy}(x,y) = f_{yx}(x,y) = e^{-(x+y)} - xe^{-(x+y)} - ye^{-(x+y)} + xye^{-(x+y)} & f_{xy}(1,1) = 0 & f_{xy}(0,0) = 1 \\ f_{yy}(x,y) = -2xe^{-(x+y)} + xye^{-(x+y)} & f_{yy}(1,1) = -e^{-2} & f_{yy}(0,0) = 0 \end{array}$$

For the critical point $(0,0)$, $f_{xx}(0,0) \cdot f_{yy}(0,0) - [f_{xy}(0,0)]^2 = -1 < 0$, so the point $(0,0,0)$ is a saddle point.

For the critical point $(1,1)$, $f_{xx}(1,1) \cdot f_{yy}(1,1) - [f_{xy}(1,1)]^2 = e^{-4} > 0$ and $f_{xx}(1,1) < 0$, so the point $(1,1)$ is a local maximum. The local maximum is at $(1,1)$ and the local maximum is $z = e^{-2}$.

33. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x,y) = 2x - 4y = 0 \\ f_y(x,y) = -4x + 4 = 0 \end{cases}$$

The only critical point is then $\left(1, \frac{1}{2}\right)$. The value of f at this point is

$$f\left(1, \frac{1}{2}\right) = 1.$$

The boundary of D is made up of the four line segments L_1 , L_2 , L_3 , and L_4 as drawn in the following picture.

On L_1 : $y = 0$ and $0 \leq x \leq 2$. The function $f(x,y) = f(x,0) = x^2$ is increasing on $0 \leq x \leq 2$ and its extreme values are $f(0,0) = 0$ and $f(2,0) = 4$.

On L_2 : $x = 2$ and $0 \leq y \leq 1$. The function $f(x,y) = f(2,y) = 4 - 4y$ is decreasing on $0 \leq y \leq 1$ and its extreme values are $f(2,1) = 0$ and $f(2,0) = 4$.

On L_3 : $y = 1$ and $0 \leq x \leq 2$. The function $f(x,y) = f(x,1) = x^2 - 4x + 4$ can be thought of as a function of a single variables, namely $g(x) = x^2 - 4x + 4$. The extreme of this function can be found by finding the critical number(s) of g , namely where $g'(x) = 2x - 4 = 0$, or $x = 2$. This means the extrema occur at the endpoints, and those extreme values are $g(2) = f(2,1) = 0$ and $g(0) = f(0,1) = 4$.

On L_4 : $x = 0$ and $0 \leq y \leq 1$. Then function $f(x,y) = f(0,y) = 4y$ is increasing on $0 \leq y \leq 1$ and its extreme values are $f(0,0) = 0$ and $f(0,1) = 4$.

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is 0 and the absolute maximum is 4.

34. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x,y) = 2x - 4y = 0 \\ f_y(x,y) = -4x + 4 = 0 \end{cases}$$

The only critical point is then $\left(1, \frac{1}{2}\right)$. The value of f at this point is

$$f\left(1, \frac{1}{2}\right) = 1.$$

The boundary of D is made up of the four line segments L_1 , L_2 , L_3 , and L_4 as drawn in the following picture.

On L_1 : $y = 0$ and $0 \leq x \leq 3$. The function $f(x, y) = f(x, 0) = x^2$ is increasing on $0 \leq x \leq 3$ and its extreme values are $f(0, 0) = 0$ and $f(3, 0) = 9$.

On L_2 : $x = 3$ and $0 \leq y \leq 2$. The function $f(x, y) = f(3, y) = 9 - 8y$ is decreasing on $0 \leq y \leq 2$ and its extreme values are $f(3, 2) = -7$ and $f(3, 0) = 9$.

On L_3 : $y = 2$ and $0 \leq x \leq 3$. The function $f(x, y) = f(x, 2) = x^2 - 8x + 8$ can be thought of as a function of a single variable, namely $g(x) = x^2 - 8x + 8$. The extreme of this function can be found by finding the critical number(s) of g , namely where $g'(x) = 2x - 8 = 0$, or $x = 4$. This value is not in the interval $0 \leq x \leq 3$, so the extrema occur at the endpoints, and those extreme values are $g(3) = f(3, 2) = -7$ and $g(0) = f(0, 2) = 8$.

On L_4 : $x = 0$ and $0 \leq y \leq 2$. Then function $f(x, y) = f(0, y) = 4y$ is increasing on $0 \leq y \leq 2$ and its extreme values are $f(0, 0) = 0$ and $f(0, 2) = 8$.

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is -7 and the absolute maximum is 9 .

35. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x + 2 = 0 \\ f_y(x, y) = 2y - 2 = 0 \end{cases}$$

The only critical point is then $(-1, 1)$. The value of f at this critical point is $f(-1, 1) = -2$.

The boundary of D is a circle of radius 2 centered at the origin which can be parameterized by $x(t) = 2 \cos t$ and $y = 2 \sin t$ for $0 \leq t \leq 2\pi$. On the boundary

$$z = f(x, y) = f(2 \cos t, 2 \sin t) = 4 \cos^2 t + 4 \cos t + 4 \sin^2 t - 4 \sin t = 4(\cos t - \sin t + 1).$$

Now we find where $z'(t) = 0$ on $0 \leq t \leq 2\pi$.

$$\begin{aligned} 4(-\sin t - \cos t) &= 0 \\ -\sin t &= \cos t \\ t &= \frac{3\pi}{4}, \frac{7\pi}{4} \end{aligned}$$

At these two critical values and the endpoints $t = 0, 2\pi$, the values of f are

$$\begin{aligned} f\left(2 \cos \frac{3\pi}{4}, 2 \sin \frac{3\pi}{4}\right) &= 4 - 4\sqrt{2} \\ f\left(2 \cos \frac{7\pi}{4}, 2 \sin \frac{7\pi}{4}\right) &= 4 + 4\sqrt{2} \\ f(2 \cos 0, 2 \sin 0) &= 8 \\ f(2 \cos 2\pi, 2 \sin 2\pi) &= 8 \end{aligned}$$

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is -2

and the absolute maximum is $4 + 4\sqrt{2}$.

36. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 4 = 0 \\ f_y(x, y) = 2y - 4 = 0 \end{cases}$$

The only critical point is then $(2, 2)$. The value of f at this critical point is $f(2, 2) = -8$.

The boundary of D is a circle of radius 3 centered at the origin which can be parameterized by $x(t) = 3 \cos t$ and $y = 3 \sin t$ for $0 \leq t \leq 2\pi$. On the boundary

$$z = f(x, y) = f(3 \cos t, 3 \sin t) = 9 \cos^2 t - 12 \cos t + 9 \sin^2 t - 12 \sin t = -12 \cos t - 12 \sin t + 9.$$

Now we find where $z'(t) = 0$ on $0 \leq t \leq 2\pi$.

$$\begin{aligned} 12 \sin t - 12 \cos t &= 0 \\ \sin t &= \cos t \\ t &= \frac{\pi}{4}, \frac{5\pi}{4}. \end{aligned}$$

At these two critical values and the endpoints $t = 0, 2\pi$, the values of f are

$$\begin{aligned} f\left(3 \cos \frac{\pi}{4}, 3 \sin \frac{\pi}{4}\right) &= 9 - 12\sqrt{2} \\ f\left(3 \cos \frac{5\pi}{4}, 3 \sin \frac{5\pi}{4}\right) &= 9 + 12\sqrt{2} \\ f(2 \cos 0, 2 \sin 0) &= -3 \\ f(2 \cos 2\pi, 2 \sin 2\pi) &= -3 \end{aligned}$$

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is -8

and the absolute maximum is $12 + 12\sqrt{2}$.

37. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = y + 4 = 0 \\ f_y(x, y) = x - 3 = 0 \end{cases}$$

The only critical point is then $(3, -4)$. The value of f at this critical point is $f(3, -4) = 17$. The boundary of D is made up of the three line segments L_1 , L_2 , and L_3 as drawn in the following picture.

On L_1 : $x = 0$ and $0 \leq y \leq 4$. The function $f(x, y) = f(0, y) = 5 - 3y$ is decreasing on $0 \leq y \leq 4$ and its extreme values are $f(0, 4) = -7$ and $f(0, 0) = 5$.

On L_2 : $y = 4$ and $0 \leq x \leq 5$. The function $f(x, y) = f(x, 4) = 8x - 7$ is increasing on $0 \leq x \leq 5$ and its extreme values are $f(0, 4) = -7$ and $f(5, 4) = 33$.

On L_3 : $y = \frac{4}{5}x$ and $0 \leq x \leq 5$. The function $f(x, y) = f\left(x, \frac{4}{5}x\right) = \frac{4}{5}x^2 + \frac{8}{5}x + 5$ can be thought of as a function of a single variable, namely $g(x) = \frac{4}{5}x^2 + \frac{8}{5}x + 5$. The extrema of g occur at the endpoints of the interval or at a critical number, which are found by setting $g'(x) = \frac{8}{5}x + \frac{8}{5} = 0$, namely $x = -1$. Since this critical number is not in the interval $0 \leq x \leq 5$ the extreme values are $g(0) = f(0, 0) = 5$ and $g(5) = f(5, 4) = 33$.

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is -7 and the absolute maximum is 33 .

38. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3y - 3 = 0 \\ f_y(x, y) = 3x - 6 = 0 \end{cases}$$

The only critical point is then $(2, 1)$. The value of f at this critical point is $f(2, 1) = -5$. The boundary of D is made up of the three line segments L_1 , L_2 , and L_3 as drawn in the following picture.

On L_1 : $y = 0$ and $0 \leq x \leq 5$. The function $f(x, y) = f(x, 0) = 1 - 3x$ is decreasing on $0 \leq x \leq 5$ and its extreme values are $f(0, 0) = 1$ and $f(5, 0) = -14$.

On L_2 : $y = 3 - \frac{3}{5}x$ and $0 \leq x \leq 5$. The function $f(x, y) = f\left(x, 3 - \frac{3}{5}x\right) = -\frac{9}{5}x^2 + \frac{48}{5}x - 17$ has a maximum when $f'\left(x, 3 - \frac{3}{5}x\right) = -\frac{18}{5}x + \frac{48}{5} = 0$, namely $x = \frac{8}{3}$. The value at this point is $f\left(\frac{8}{3}\right) = -\frac{21}{5}$. Testing the endpoints of the interval $0 \leq x \leq 5$, we find that $f(0, 3) = -17$ and $f(5, 0) = -14$. Then the extreme values on L_2 are $f(0, 3) = -17$ and $f\left(\frac{8}{3}\right) = -\frac{21}{5}$.

On L_3 : $x = 0$ and $0 \leq y \leq 3$. The function $f(x, y) = f(0, y) = 1 - 6y$ is decreasing on $0 \leq y \leq 3$ and its extreme values are $f(0, 3) = -17$ and $f(0, 0) = 1$.

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is -17 and the absolute maximum is 1 .

Applications and Extensions

39. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = \cos x \sin y = 0 \\ f_y(x, y) = \sin x \cos y = 0 \end{cases}$$

From the first equation, we see that $x = n\pi + \frac{\pi}{2}$ or $y = n\pi$ for any integer n .

If $x = n\pi + \frac{\pi}{2}$, then the second equation implies $y = m\pi + \frac{\pi}{2}$ for any integer m .

If $y = n\pi$, then the second equation implies $x = m\pi$ for any integer m .

The second-order partial derivatives are as follows.

$$\begin{aligned} f_{xx}(x, y) &= -\sin x \sin y \\ f_{xy}(x, y) &= f_{yx}(x, y) = \cos x \cos y \\ f_{yy}(x, y) &= -\sin x \sin y \end{aligned}$$

For the critical points $\left(-\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right)$ and $\left(\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right)$, we have that

$$f_{xx}\left(-\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right) \cdot f_{yy}\left(-\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right) - \left[f_{xy}\left(-\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right)\right]^2 = 1 > 0$$

$$f_{xx}\left(\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right) \cdot f_{yy}\left(\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right) - \left[f_{xy}\left(\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right)\right]^2 = 1 > 0$$

$$f_{xx}\left(-\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right) = 1 > 0 \text{ and } f_{xx}\left(\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right) = 1 > 0.$$

This means we have local minima at the points $\left(-\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right)$ and $\left(\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right)$ and

the local minimum is $z = -1$.

For the critical points $\left(-\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right)$ and $\left(\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right)$, we have that

$$f_{xx}\left(-\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right) \cdot f_{yy}\left(-\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right) - \left[f_{xy}\left(-\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right)\right]^2 = 1 > 0$$

$$f_{xx}\left(\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right) \cdot f_{yy}\left(\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right) - \left[f_{xy}\left(\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right)\right]^2 = 1 > 0$$

$$f_{xx}\left(-\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right) = -1 < 0 \text{ and } f_{xx}\left(\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right) = -1 < 0.$$

This means we have local maxima at the points $\left(-\frac{\pi}{2} + 2\pi m, -\frac{\pi}{2} + 2\pi n\right)$ and $\left(\frac{\pi}{2} + 2\pi m, \frac{\pi}{2} + 2\pi n\right)$ and

the local maximum is $z = 1$.

For the critical points $(m\pi, n\pi)$,

$$f_{xx}(m\pi, n\pi) \cdot f_{yy}(m\pi, n\pi) - [f_{xy}(m\pi, n\pi)]^2 = -1 < 0,$$

so the points $(m\pi, n\pi, 0)$ are saddle points.

40. (a) By completing the square for both x and y , the equation becomes

$$\begin{aligned} (x-3)^2 + (y+2)^2 + z &= -12 + 9 + 4 \\ z &= -(x-3)^2 - (y+2)^2 + 1. \end{aligned}$$

The value of z is largest when $x = 3$ and $y = -2$, so the vertex is $(3, -2, 1)$.

(b) To find the vertex, we will find the local maximum. We start by finding the critical point, which is the solution of the system of equations

$$\begin{cases} f_x(x, y) = -2x + 6 = 0 \\ f_y(x, y) = -2y - 4 = 0 \end{cases}$$

The only critical point is then $(3, -2)$. The second-order partial derivatives and their values at $(3, -2)$ are as follows.

$$\begin{aligned} f_{xx}(x, y) &= -2 & A &= f_{xx}(3, -2) = -2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & B &= f_{xy}(3, -2) = 0 \\ f_{yy}(x, y) &= -2 & C &= f_{yy}(3, -2) = -2 \\ AC - B^2 &= 4 \end{aligned}$$

Since $AC - B^2 > 0$ and $f_{xx}(3, -2) < 0$, the point $(3, -2, 1)$ is indeed the local maximum, which is the vertex of the paraboloid.

41. The highest point on the mountain is the vertex, which is the critical point, found by solving the system of equations

$$\begin{cases} f_x(x, y) = 2y - 4x - 8 = 0 \\ f_y(x, y) = 2x - 2y + 6 = 0 \end{cases}$$

Solving for y in the f_x equation and plugging it into the f_y equation, we have

$$\begin{aligned} 2x - 2(2x + 4) + 6 &= 0 \\ -2x &= 2 \\ x &= -1 \end{aligned}$$

so that $y = 2$. This means at its highest peak, the mountain is $\boxed{z(-1, 2) = 14 \text{ kilometers}}$ above sea level.

42. (a) Instead of minimizing the distance from the plane to the origin, we will, equivalently, minimize the *square* of the distance from the plane to the origin. Let (x, y, z) be some point on the plane, so $z = 14 - 3x - 2y$. The square of the distance from (x, y, z) to the origin is

$$f(x, y) = (x - 0)^2 + (y - 0)^2 + (z - 0)^2 = x^2 + y^2 + (14 - 3x - 2y)^2.$$

We now need to find the absolute minimum of f on the real plane. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = 20x + 12y - 84 = 0 \\ f_y(x, y) = 12x + 10y - 56 = 0 \end{cases}$$

Solving for y in the f_y equation and plugging it into the f_x equation, we have

$$\begin{aligned} 20x + 12\left(\frac{56 - 12x}{10}\right) - 84 &= 0 \\ 28x - 84 &= 0 \\ x &= 3, \end{aligned}$$

which means $y = 2$. The only critical point is $(3, 2)$. The second-order partial derivatives and their values at $(3, 2)$ are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 20 & A &= f_{xx}(3, 2) = 20 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 12 & B &= f_{xy}(3, 2) = 12 \\ f_{yy}(x, y) &= 10 & C &= f_{yy}(3, 2) = 10 \\ AC - B^2 &= 56 \end{aligned}$$

Since $AC - B^2 > 0$ and $f_{xx}(3, 2) = 20 > 0$, the point $(3, 2)$ is a local minimum. Since the physical properties of the problem require that the absolute minimum exists, the local minimum is also the absolute minimum. So the point in the plane closest to the origin is $\boxed{(3, 2, 1)}$.

(b) The distance from the origin to the point $(3, 2, 1)$ is

$$\sqrt{3^2 + 2^2 + 1^2} = \boxed{\sqrt{14}}.$$

43. If we let l , w , and h be the length, width, and height of the box, respectively, then on one hand the surface area of the box is S and on the other hand it is $2lh + 2wh + lw$, so

$$S = 2lh + 2wh + lw.$$

The volume of the box is

$$V(l, w, h) = lwh \quad l > 0, \quad w > 0, \quad h > 0.$$

Solving for h in the surface area equation, we have $h = \frac{S - lw}{2l + 2w}$. Plugging this into the volume function, we have

$$V(l, w) = \frac{Slw - l^2w^2}{2l + 2w}.$$

Since $l > 0$ and $w > 0$, the only critical points of V will come from solving the system of equations

$$\begin{cases} V_l(l, w) = \frac{(2l + 2w)(Sw - 2lw^2) - (Slw - l^2w^2)(2)}{(2l + 2w)^2} = \frac{w^2(S - 2lw - l^2)}{2(l + w)^2} = 0 \\ V_w(l, w) = \frac{(2l + 2w)(Sl - 2l^2w) - (Slw - l^2w^2)(2)}{(2l + 2w)^2} = \frac{l^2(S - 2lw - w^2)}{2(l + w)^2} = 0 \end{cases}$$

Since both l and w are positive, we need to solve the system

$$\begin{cases} S - 2lw - l^2 = 0 \\ S - 2lw - w^2 = 0 \end{cases}$$

Subtracting the first equation from the second, we find that $l^2 = w^2$. Again since l and w are both positive, it must be that $l = w$. Then using the first equation in the system and the fact that $l = w$,

$$\begin{aligned} S - 2l^2 - l^2 &= 0 \\ 3l^2 &= S \\ l &= \sqrt{\frac{S}{3}} \\ w &= \sqrt{\frac{S}{3}}. \end{aligned}$$

Then

$$h = \frac{S - l^2}{2l + 2l} = \frac{S - l^2}{4l} = \frac{S - \frac{S}{3}}{4\sqrt{\frac{S}{3}}} = \frac{\sqrt{3S}}{6}.$$

The dimensions that maximize volume are when the length and width are $\sqrt{\frac{S}{3}}$ and the height is $\frac{\sqrt{3S}}{6} = \frac{1}{2}\sqrt{\frac{S}{3}}$.

44. If we let l , w , and h be the length, width, and height of the box, respectively, then on one hand the surface area of the box is S and on the other hand it is $2lh + 2wh + 2lw$, so

$$S = 2lh + 2wh + 2lw.$$

The volume of the box is

$$V(l, w, h) = lwh \quad l > 0, \quad w > 0, \quad h > 0.$$

Solving for h in the surface area equation, we have $h = \frac{S - 2lw}{2l + 2w}$. Plugging this into the volume function, we have

$$V(l, w) = \frac{Slw - 2l^2w^2}{2l + 2w}.$$

Since $l > 0$ and $w > 0$, the only critical points of V will come from solving the system of equations

$$\begin{cases} V_l(l, w) = \frac{(2l + 2w)(Sw - 4lw^2) - (Slw - 2l^2w^2)(2)}{(2l + 2w)^2} = \frac{w^2(S - 4lw - 2l^2)}{2(l + w)^2} = 0 \\ V_w(l, w) = \frac{(2l + 2w)(Sl - 4l^2w) - (Slw - 2l^2w^2)(2)}{(2l + 2w)^2} = \frac{l^2(S - 4lw - 2w^2)}{2(l + w)^2} = 0 \end{cases}$$

Since both l and w are positive, we need to solve the system

$$\begin{cases} S - 4lw - 2l^2 = 0 \\ S - 4lw - 2w^2 = 0 \end{cases}$$

Subtracting the first equation from the second, we find that $2l^2 = 2w^2$. Again since l and w are both positive, it must be that $l = w$. Then using the first equation in the system and the fact that $l = w$,

$$\begin{aligned} S - 4l^2 - 2l^2 &= 0 \\ 6l^2 &= S \\ l &= \sqrt{\frac{S}{6}} \\ w &= \sqrt{\frac{S}{6}}. \end{aligned}$$

Then

$$h = \frac{S - 2l^2}{2l + 2l} = \frac{S - 2l^2}{4l} = \frac{S - 2 \cdot \frac{S}{6}}{4\sqrt{\frac{S}{6}}} = \sqrt{\frac{S}{6}}.$$

The dimensions that maximize volume are when the length, width, and height are all $\sqrt{\frac{S}{6}}$.

45. It will be beneficial to read the solution to Example 7 before reading this solution. Since the box is closed, the surface area S function is now

$$S = 2xy + 2xz + 2yz.$$

The volume V equation is still $V = 500 = xyz$ so $z = \frac{500}{xy}$, making the surface area function

$$S(x, y) = 2xy + \frac{1000}{y} + \frac{1000}{x}.$$

The critical points of S satisfy the system of equations

$$\begin{cases} S_x(x, y) = 2y - \frac{1000}{x^2} = 0 \\ S_y(x, y) = 2x - \frac{1000}{y^2} = 0 \end{cases}$$

Solving for y in the first equation, we have $y = \frac{500}{x^2}$. Plugging this into the second equation, we have

$$\begin{aligned} 2x - \frac{1000}{(500/x^2)^2} &= 0 \\ 2x - \frac{1}{250}x^4 &= 0 \\ 2 - \frac{1}{250}x^3 &= 0 \\ x &= \sqrt[3]{500}, \end{aligned}$$

so $y = \sqrt[3]{500}$ too.

The second-order partial derivatives of S are

$$S_{xx} = \frac{2000}{x^3} \quad S_{xy} = S_{yx} = 2 \quad S_{yy} = \frac{2000}{y^3}.$$

At the critical point $(\sqrt[3]{500}, \sqrt[3]{500})$,

$$A = S_{xx}(\sqrt[3]{500}, \sqrt[3]{500}) = 4 \quad B = S_{xy}(\sqrt[3]{500}, \sqrt[3]{500}) = 2 \quad C = S_{yy}(\sqrt[3]{500}, \sqrt[3]{500}) = 4,$$

so $AC - B^2 > 0$ and $A > 0$ which means $(\sqrt[3]{500}, \sqrt[3]{500})$ is a local minimum. Since the physical properties of the problem require that the absolute minimum exists, the local minimum is the absolute minimum. Using the equation $z = \frac{500}{xy}$, we find that $z = \sqrt[3]{500}$. The dimensions of the box that yield the least possible

amount of material are when $x = y = z = \sqrt[3]{500}$ centimeters.

46. If x, y, z are the length, width, and height of the box, then the cost function is given by

$$C(x, y, z) = 4xy + 3xz + 2(xz + 2yz) = 4xy + 5xz + 4yz,$$

where the side costing \$3 per square meter is the side with area xz . The volume V equation is $V = 80 = xyz$ so $z = \frac{80}{xy}$, making the cost function

$$C(x, y) = 4xy + \frac{400}{y} + \frac{320}{x}.$$

The critical points of C satisfy the system of equations

$$\begin{cases} C_x(x, y) = 4y - \frac{320}{x^2} = 0 \\ C_y(x, y) = 4x - \frac{400}{y^2} = 0 \end{cases}$$

Solving for y in the first equation, we have $y = \frac{80}{x^2}$. Plugging this into the second equation, we have

$$\begin{aligned} 4x - \frac{400}{(80/x^2)^2} &= 0 \\ 4x - \frac{1}{16}x^4 &= 0 \\ 4 - \frac{1}{16}x^3 &= 0 \\ x &= 4, \end{aligned}$$

so this makes $y = 5$.

The second-order partial derivatives of C are

$$C_{xx} = \frac{640}{x^3} \quad C_{xy} = C_{yx} = 4 \quad C_{yy} = \frac{800}{y^3}.$$

At the critical point $(4, 5)$,

$$A = C_{xx}(4, 5) = 10 \quad B = C_{xy}(4, 5) = 4 \quad C = C_{yy}(4, 5) = \frac{32}{5},$$

so $AC - B^2 > 0$ and $A > 0$ which means $(4, 5)$ is a local minimum. Since the physical properties of the problem require that the absolute minimum exists, the local minimum is the absolute minimum. The dimensions of the box that yield the least possible amount of material are when

$$\text{length is } x = 4 \text{ meters, width is } y = 5 \text{ meters, and height is } z = \frac{80}{4 \cdot 5} = 4 \text{ meters}.$$

47. (a) If x, y, z are the length, width, and height of the box, then the length plus the girth is $x + 2y + 2z$. In order to maximize the volume, we want the length plus the girth to be as large as possible, which means $x + 2y + 2z = 130$, or $x = 130 - 2y - 2z$. The volume function V is then

$$\begin{aligned} V(x, y, z) &= xyz \\ V(y, z) &= yz(130 - 2y - 2z) = 130yz - 2zy^2 - 2yz^2. \end{aligned}$$

The critical points of V satisfy the system of equations

$$\begin{cases} V_y(y, z) = 130z - 4yz - 2z^2 = 2z(65 - 2y - z) = 0 \\ V_z(y, z) = 130y - 2y^2 - 4yz = 2y(65 - y - 2z) = 0 \end{cases}$$

Since $y > 0$ and $z > 0$ we need to solve the system

$$\begin{cases} 65 - 2y - z = 0 \\ 65 - y - 2z = 0 \end{cases}$$

Using substitution, $y = z = \frac{65}{3}$. This means $x = \frac{130}{3}$. The second-order partial derivatives of V and their values at the critical point $(y, z) = \left(\frac{65}{3}, \frac{65}{3}\right)$ are

$$\begin{aligned} V_{yy}(y, z) &= -4z & A &= V_{yy}\left(\frac{65}{3}, \frac{65}{3}\right) = -\frac{260}{3} \\ V_{yz}(y, z) &= V_{zy}(y, z) = 130 - 4y - 4z & B &= V_{yz}\left(\frac{65}{3}, \frac{65}{3}\right) = -\frac{130}{3} \\ V_{zz}(y, z) &= -4y & C &= V_{zz}\left(\frac{65}{3}, \frac{65}{3}\right) = -\frac{260}{3} \end{aligned}$$

Since $AC - B^2 = \frac{16900}{3} > 0$ and $A < 0$, the critical point is a local maximum. Since the physical properties of the problem require that the absolute maximum exists, the local maximum is the absolute maximum. This means the dimensions that yield maximum possible volume of a box to be shipped are

$$\boxed{\frac{65}{3} \text{ inches for the width and height, and } \frac{130}{3} \text{ inches for the length.}}$$

(b) If the package is cylindrical, then let x be the length and r the radius of a cross sectional circle. Then the length plus the girth is $x + 2\pi r$. In order to maximize the volume, we want the length plus the girth to be as large as possible, which means $x + 2\pi r = 130$, or $x = 130 - 2\pi r$. The volume function V is then

$$\begin{aligned} V(x, r) &= \pi r^2 x \\ V(r) &= \pi r^2 (130 - 2\pi r) = 130\pi r^2 - 2\pi^2 r^3. \end{aligned}$$

The critical values are the solutions to

$$V'(r) = 260\pi r - 6\pi^2 r^2 = \pi r(260 - 6\pi r) = 0.$$

Since $r > 0$, it must be that $r = \frac{130}{3\pi}$. Now we find the second derivative and it's value at $r = \frac{130}{3\pi}$.

$$V''(r) = 260\pi - 12\pi^2 r \quad V''\left(\frac{130}{3\pi}\right) = -260\pi < 0$$

so by the Second-Derivatives Test, this critical value is a local maximum, but must also be the absolute maximum since it is the only critical value. This means when the

radius of the package is $\frac{130}{3\pi}$ inches and the

length is $130 - \frac{2\pi \cdot 130}{3\pi} = \frac{130}{3}$ inches, the package will have maximum possible volume.

48. The critical points are solutions of the system of equations

$$\begin{cases} y_x(t, x) = 2x(a - x)te^{-t} - x^2te^{-t} = te^{-t}x(-3x + 2a) = 0 \\ y_t(t, x) = x^2(a - x)e^{-t} - x^2(a - x)te^{-t} = x^2(a - x)e^{-t}(1 - t) = 0 \end{cases}$$

From the first equation, we see that either $t = 0$, $x = 0$, or $x = \frac{2a}{3}$.

If $t = 0$, then the y_t equation simplifies to $x^2(a - x) = 0$, which has solutions $x = 0$ and $x = a$. So two critical points are $(0, 0)$ and $(0, a)$. The values of y at these point are $y(0, 0) = 0$ and $y(0, a) = 0$.

If $x = 0$, then the y_t equation is true for any value of t , so the points $(t, 0)$ are critical points for $t \geq 0$. However, $y(t, x) \geq 0$, and if $x = 0$, then $y(t, 0) = 0$, so any point where $x = 0$ cannot maximize y .

If $x = \frac{2a}{3}$, then the y_t equation simplifies to $\frac{4a^3}{27}e^{-t}(1 - t)$, which has solution $t = 1$. So the last critical point is $\left(1, \frac{2a}{3}\right)$. The value of y at this critical point is $y\left(1, \frac{2a}{3}\right) = \frac{4a^3}{27}e^{-1}$. The value $\frac{4a^3}{27}e^{-1}$ is the maximum value of y and can be seen as follows. The function y is the product of $x^2(a - x)$ and te^{-t} , which are two functions independent of each other in terms of the variables t and x . As we found above, the first function $x^2(a - x)$ is maximized when $x = \frac{2a}{3}$ and the second is maximized when $t = 1$.

49. (a) If x is fixed, say at x_0 , then

$$f(y) = R(x_0, y) = x_0^2 y^2 (a - x_0)(b - y).$$

To maximize y , we find f' and set it equal to 0.

$$\begin{aligned} f'(y) &= 2x_0^2 y(a - x_0)(b - y) - x_0^2 y^2(a - x_0) = 0 \\ x_0^2 y(a - x_0)(2(b - y) - y) &= 0 \\ x_0^2 y(a - x_0)(2b - 3y) &= 0 \\ y &= 0, \frac{2b}{3}. \end{aligned}$$

If we plug in $y = 0$, then $R(x_0, 0) = 0$, so the maximum must occur when $y = \frac{2b}{3}$.

(b) By symmetry of the function, it must also be that the maximum must occur when $x = \frac{2a}{3}$.

(c) Since $R(x, y) = (x^2(a - x))(y^2(b - x))$, maximizing R amounts to maximizing $x^2(a - x)$ and $y^2(b - x)$, which we did in parts (a) and (b), so the amount that maximizes the reaction is when $x = \frac{2a}{3}$ and $y = \frac{2b}{3}$.

50. (a) For maximum possible flow, we want the area of the cross section shown in the picture to be maximized. The length of the top is $2b + L - 2x$ where b is labelled in the following picture.

The area of a trapezoid with base lengths b_1 and b_2 and height h is $\frac{1}{2}(b_1 + b_2)h$, so the area of the cross section is

$$A(h, x) = \frac{1}{2}(2b + L - 2x)h = \frac{1}{2}(2\sqrt{x^2 - h^2} + L - 2x)h, \quad h > 0, \quad x > 0.$$

The critical points are solutions of the system of equations

$$\begin{cases} A_x(h, x) = \frac{1}{2} \left(\frac{2x}{\sqrt{x^2 - h^2}} - 4 \right) h = \frac{x - 2\sqrt{x^2 - h^2}}{\sqrt{x^2 - h^2}} \cdot h = 0 \\ A_h(h, x) = -\frac{h^2}{\sqrt{x^2 - h^2}} + \sqrt{x^2 - h^2} + L - 2x = \frac{-2h^2 + x^2 + L\sqrt{x^2 - h^2} - 2x\sqrt{x^2 - h^2}}{\sqrt{x^2 - h^2}} = 0 \end{cases}$$

Since $b = \sqrt{x^2 - h^2}$ could be 0, we have to consider the case $x = h$ separately from $x \neq h$.

If $x = h$ (then the opening is rectangular, and not trapezoidal), then $A(h, x) = xL - 2x^2$ which is maximized when $\frac{d(xL - 2x^2)}{dx} = L - 4x = 0$, or $x = \frac{L}{4}$. In this case $A\left(\frac{L}{4}, \frac{L}{4}\right) = \frac{L^2}{8}$.

If $x \neq h$, then the system above becomes

$$\begin{cases} A_x(h, x) = (x - 2\sqrt{x^2 - h^2}) \cdot h = 0 \\ A_h(h, x) = -2h^2 + x^2 + L\sqrt{x^2 - h^2} - 2x\sqrt{x^2 - h^2} = 0 \end{cases}$$

From the first equation, either $x - 2\sqrt{x^2 - h^2} = 0$ or $h = 0$. Since $h > 0$, we must have

$$\begin{aligned} x - 2\sqrt{x^2 - h^2} &= 0 \\ x &= 2\sqrt{x^2 - h^2} \\ x^2 &= 4x^2 - 4h^2 \\ 3x^2 &= 4h^2 \\ x &= \frac{2}{\sqrt{3}}h. \end{aligned}$$

Plugging this into the second equation

$$\begin{aligned} -2h^2 + x^2 + L\sqrt{x^2 - h^2} - 2x\sqrt{x^2 - h^2} &= 0 \\ -\frac{2}{3}h^2 + \frac{Lh}{\sqrt{3}} - \frac{4}{3}h^2 &= 0 \\ \frac{1}{3}h(-6h + L\sqrt{3}) &= 0 \\ h &= \frac{L\sqrt{3}}{6}, \end{aligned}$$

since $h > 0$. So $x = \frac{2}{\sqrt{3}}h = \frac{1}{3}L$. In this case

$$\begin{aligned} A\left(\frac{L\sqrt{3}}{6}, \frac{1}{3}L\right) &= \frac{1}{2}\left(2\sqrt{\frac{L^2}{9} - \frac{L^2}{12}} + 2\left(L - \frac{2}{3}L\right)\right) \cdot \frac{L\sqrt{3}}{6} \\ &= \frac{L\sqrt{3}}{12}\left(\frac{1}{3}L + \frac{2}{3}L\right) = \frac{\sqrt{3}}{12}L^2 > \frac{L^2}{8}. \end{aligned}$$

Comparing the values of A for the $x = h$ and $x \neq h$ cases, we see that the maximum possible flow is allowed

when $\boxed{h = \frac{L\sqrt{3}}{6}}$ and $\boxed{x = \frac{L}{3}}$.

(b) If we created a semicircular channel, then the length of semicircle would be $L = \pi r$, where r is the radius of the channel. The area of a cross section would be

$$A = \frac{1}{2}\pi\left(\frac{L}{\pi}\right)^2 = \frac{L^2}{2\pi} > \frac{\sqrt{3}}{12}L^2,$$

which means $\boxed{\text{the semicircular shape would be preferable to the trapezoidal shape}}.$

51. We first find the critical points of F , namely the solutions of the system of equations

$$\begin{cases} F_x(x, y) = 12x - 4 = 0 \\ f_y(x, y) = 12y - 6 = 0 \end{cases}$$

The only critical point is then $\left(\frac{1}{3}, \frac{1}{2}\right)$. The second-order partial derivatives and their values at $\left(\frac{1}{3}, \frac{1}{2}\right)$ are

as follows.

$$\begin{aligned} F_{xx}(x, y) &= 12 & A &= F_{xx}\left(\frac{1}{3}, \frac{1}{2}\right) = 12 \\ F_{xy}(x, y) &= F_{yx}(x, y) = 0 & B &= F_{xy}\left(\frac{1}{3}, \frac{1}{2}\right) = 0 \\ F_{yy}(x, y) &= 12 & C &= F_{yy}\left(\frac{1}{3}, \frac{1}{2}\right) = 12 \\ AC - B^2 &= 144 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$, $\left(\frac{1}{3}, \frac{1}{2}\right)$ is a local minimum. Since the physical properties of the problem require that the absolute minimum exists, the local minimum is also the absolute minimum. So the fuel reservoir should be located at the point $\boxed{\left(\frac{1}{3}, \frac{1}{2}\right)}$.

52. If l, w, h represent the length, width, and height of the shipping container, then the top and bottom have surface area lw , two of the sides have surface area lh , and the other two sides have surface area wh . The cost C of the box is then

$$C(l, w, h) = a(2lh + 2wh) + \frac{3}{2}a(2lw).$$

Since the volume is to be $\frac{3}{2}$, we have $lwh = \frac{3}{2}$, or $h = \frac{3}{2lw}$. With this equation, the cost function becomes

$$C(l, w) = \frac{3a}{w} + \frac{3a}{l} + 3alw, \quad w > 0, \quad l > 0.$$

We first find the critical points of C , namely the solutions of the system of equations

$$\begin{cases} C_l(l, w) = -3al^{-2} + 3aw = 0 \\ C_w(l, w) = -3aw^{-2} + 3al = 0 \end{cases}$$

Solving for w in the C_l equation and plugging it into the C_w equation, we have

$$\begin{aligned} -3a\left(\frac{1}{l^2}\right) + 3al &= 0 \\ l &= \frac{1}{l^2} \\ l &= 1, \end{aligned}$$

so $w = 1$. The second-order partial derivatives and their values at $(1, 1)$ are as follows.

$$\begin{aligned} C_{ll}(l, w) &= 6al^{-3} & A &= C_{ll}(1, 1) = 6a \\ C_{lw}(l, w) &= C_{wl} = 3a & B &= C_{lw}(1, 1) = 3a \\ C_{ww}(l, w) &= 6aw^{-3} & C &= C_{ww}(1, 1) = 6a \\ AC - B^2 &= 27a^2 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$ (since $a > 0$), the point $(1, 1)$ is a local minimum. Since the physical properties of the problem require that the absolute minimum exists, the local minimum is also the absolute minimum. The dimensions of the container that yield minimum cost are

$$\boxed{\text{length is 1 foot, width is 1 foot, and height is } \frac{3}{2 \cdot 1 \cdot 1} = \frac{3}{2} \text{ feet}}.$$

53. We first find the critical points of $M(x, y) = yx - yx^2 - y^2$, namely the solutions of the system of equations

$$\begin{cases} M_x(x, y) = y(1 - 2x) = 0 \\ M_y(x, y) = x - x^2 - 2y = 0 \end{cases}$$

Solving for y in the M_y equation and plugging it into the M_x equation, we have

$$\begin{aligned}\left(\frac{x-x^2}{2}\right)(1-2x) &= 0 \\ x(1-x)(1-2x) &= 0 \\ x &= 0, 1, \frac{1}{2}.\end{aligned}$$

This means the critical points are $(0, 0), (1, 0), \left(\frac{1}{2}, \frac{1}{8}\right)$. The values of M at these critical points are

$$M(0, 0) = 0 \quad M(1, 0) = 0 \quad M\left(\frac{1}{2}, \frac{1}{8}\right) = \frac{1}{64}.$$

Along the boundary where $x = 0$ or $y = 0$, $M \leq 0$ so the highest reading has to occur at the point $\boxed{\left(\frac{1}{2}, \frac{1}{8}\right)}$.

54. First,

$$\begin{aligned}P = R - C &= \left(2700x - \frac{3}{20}x^2 + 1000y - y^2 + \frac{1}{2}xy + 10000\right) - \left(\frac{1}{20}x^2 + 700x + y^2 - 150y - \frac{1}{2}xy\right) \\ &= 2000x - \frac{1}{5}x^2 + 1150y - 2y^2 + xy + 10000.\end{aligned}$$

We find the critical points of P , namely the solutions of the system of equations

$$\begin{cases} P_x(x, y) = 2000 - \frac{2}{5}x + y = 0 \\ P_y(x, y) = 1150 - 4y + x = 0 \end{cases}$$

Solving for y in the P_x equation and plugging it into the P_y equation, we have

$$\begin{aligned}1150 - 4\left(\frac{2}{5}x - 2000\right) + x &= 0 \\ x &= 15250,\end{aligned}$$

so $y = 4100$. The second-order partial derivatives and their values at $(15250, 4100)$ are as follows.

$$\begin{aligned}P_{xx}(x, y) &= -\frac{2}{5} & A = P_{xx}(15250, 4100) &= -\frac{2}{5} \\ P_{xy}(x, y) &= P_{yx}(x, y) = 1 & B = P_{xy}(15250, 4100) &= 1 \\ P_{yy}(x, y) &= -4 & C = P_{yy}(15250, 4100) &= -4 \\ AC - B^2 &= \frac{3}{5}\end{aligned}$$

Since $AC - B^2 > 0$ and $A < 0$, the point $(15250, 4100)$ is a local maximum, which is then the absolute maximum based on the nature of the problem. When $\boxed{15250 \text{ kilograms of Grade A steel}}$ and $\boxed{4100 \text{ kilograms of Grade B steel}}$ is used in the manufacturing, the profit will be maximized.

55. The revenue R can be found by multiplying the price of each item by the number of such items sold. That is,

$$R(x, y) = x(12 - x) + y(8 - y) = 12x - x^2 + 8y - y^2.$$

Then the profit function is

$$P(x, y) = R(x, y) - C(x, y) = 12x - 2x^2 + 8y - 4y^2 - 2xy.$$

We find the critical points of P , namely the solutions of the system of equations

$$\begin{cases} P_x(x, y) = 12 - 4x - 2y = 0 \\ P_y(x, y) = 8 - 8y - 2x = 0 \end{cases}$$

Solving for y in the P_x equation and plugging it into the P_y equation, we have

$$\begin{aligned} 8 - 8(6 - 2x) - 2x &= 0 \\ 14x &= 40 \\ x &= \frac{20}{7}, \end{aligned}$$

so $y = \frac{2}{7}$. The second-order partial derivatives and their values at $\left(\frac{20}{7}, \frac{2}{7}\right)$ are as follows.

$$\begin{aligned} P_{xx}(x, y) &= -4 & A = P_{xx}\left(\frac{20}{7}, \frac{2}{7}\right) &= -4 \\ P_{xy}(x, y) = P_{yx}(x, y) &= -2 & B = P_{xy}\left(\frac{20}{7}, \frac{2}{7}\right) &= -2 \\ P_{yy}(x, y) &= -8 & C = P_{yy}\left(\frac{20}{7}, \frac{2}{7}\right) &= -8 \\ AC - B^2 &= 28 \end{aligned}$$

Since $AC - B^2 > 0$ and $A < 0$, the point $\left(\frac{20}{7}, \frac{2}{7}\right)$ is a local maximum, which is then the absolute maximum

based on the nature of the problem. The maximum profit occurs when $x = \frac{20}{7}$ thousand units are sold and

$y = \frac{2}{7}$ thousand units are sold which makes the prices $p = \frac{64}{7}$ thousand dollars and $q = \frac{54}{7}$ thousand dollars, and the maximum profit is

$$P\left(\frac{20}{7}, \frac{2}{7}\right) = \frac{128}{7} \approx \$18,286.$$

56. We find the critical points of Q , namely the solutions of the system of equations

$$\begin{cases} Q_x(x, y) = 2x - y - 3 = 0 \\ Q_y(x, y) = 2y - x - 6 = 0 \end{cases}$$

Solving for y in the Q_x equation and plugging it into the Q_y equation, we have

$$\begin{aligned} 2(2x - 3) - x - 6 &= 0 \\ 3x &= 12 \\ x &= 4, \end{aligned}$$

so $y = 5$. The second-order partial derivatives and their values at $(4, 5)$ are as follows.

$$\begin{aligned} Q_{xx}(x, y) &= 2 & A = Q_{xx}(4, 5) &= 2 \\ Q_{xy}(x, y) = Q_{yx}(x, y) &= -1 & B = Q_{xy}(4, 5) &= -1 \\ Q_{yy}(x, y) &= 2 & C = Q_{yy}(4, 5) &= 2 \\ AC - B^2 &= 3 \end{aligned}$$

Since $AC - B^2 > 0$ and $Q_{xx}(4, 5) > 0$, the point $(4, 5)$ is a local minimum. This means that labor cost is minimized when $x = 4$ and $y = 5$.

57. We find the critical points of g , namely the solutions of the system of equations

$$\begin{cases} g_x(x, y) = 2Ax + 2By = 0 \\ g_y(x, y) = 2Bx + 2Cy = 0 \end{cases}$$

Solving for x in the g_x equation (assuming $A \neq 0$) and plugging it into the g_y equation, we have

$$\begin{aligned} 2B \left(-\frac{By}{A} \right) + 2Cy &= 0 \\ y \left(-\frac{B^2}{A} + C \right) &= 0 \\ y &= 0, \end{aligned}$$

so $x = 0$ too making $(0, 0)$ the only critical point. Now we find the second-order partial derivatives, and their values at $(0, 0)$.

$$\begin{aligned} g_{xx}(x, y) &= 2A & g_{xx}(0, 0) &= 2A \\ g_{xy}(x, y) &= g_{yx}(x, y) = 2B & g_{xy}(0, 0) &= 2B \\ g_{yy}(x, y) &= 2C & g_{yy}(0, 0) &= 2C \end{aligned}$$

Notice that

$$g_{xx}(0, 0) \cdot g_{yy}(0, 0) - (g_{xy}(0, 0))^2 = 4(AC - B^2).$$

Call this quantity D . If $AC - B^2 > 0$ and $A < 0$, then $D > 0$ and $g_{xx}(0, 0) < 0$, so $(0, 0)$ is a local maximum. If $AC - B^2 > 0$ and $A > 0$, then $D > 0$ and $g_{xx}(0, 0) > 0$, so $(0, 0)$ is a local minimum.

(b) If $AC - B^2 < 0$, then $D < 0$ so $(0, 0, 0)$ is a saddle point.

Challenge Problems

58. In this problem, we will, equivalently, minimize the *square* of the distance between the two lines. A general point on L_1 looks like $(t - 6, t, 2t)$ for some value of t and a general point on L_2 looks like $(s, s, -s)$ for some value of s . Then the square of the distance between these general points is

$$f(s, t) = (t - 6 - s)^2 + (t - s)^2 + (2t + s)^2 = 6t^2 - 12t + 36 + 12s + 3s^2.$$

The critical points are solutions of the system of equations

$$\begin{cases} f_s(s, t) = 12 + 6s = 0 \\ f_t(s, t) = 12t - 12 = 0 \end{cases}$$

The only solution is $s = -2, t = 1$, so the only critical point is $(-2, 1)$. The second-order partial derivatives and their values at $(-2, 1)$ are as follows.

$$\begin{aligned} f_{ss}(s, t) &= 6 & A &= f_{ss}(-2, 1) = 6 \\ f_{st}(s, t) &= f_{ts}(s, t) = 0 & B &= f_{st}(-2, 1) = 0 \\ f_{tt}(s, t) &= 12 & C &= f_{tt}(-2, 1) = 12 \\ AC - B^2 &= 72 \end{aligned}$$

Since $AC - B^2 > 0$ and $f_{ss}(-2, 1) > 0$, this critical point is a local minimum, which by the characteristics of the problem guarantee it is also an absolute minimum. This means the distance between the two lines is the distance between the two points: on L_1 when $t = 1$, $(-5, 1, 2)$ and on L_2 when $s = -2$, $(-2, -2, 2)$. The distance between the two lines is then

$$\sqrt{(-5 - (-2))^2 + (1 - (-2))^2 + (2 - 2)^2} = \boxed{3\sqrt{2}}.$$

59. (a) Define

$$f(b, m) = \sum_{k=1}^n (mx_k + b - y_k)^2.$$

In order to minimize f , we will find the critical points by solving the system

$$\begin{cases} f_b(b, m) = \sum_{k=1}^n 2(mx_k + b - y_k) = 0 \\ f_m(b, m) = \sum_{k=1}^n 2x_k(mx_k + b - y_k) = 0 \end{cases}$$

Using properties of summations, we can rewrite these equations

$$\begin{aligned} f_b(b, m) &= 2m \sum_{k=1}^n x_k + 2bn - 2 \sum_{k=1}^n y_k = 0 \\ f_m(b, m) &= 2m \sum_{k=1}^n x_k^2 + 2b \sum_{k=1}^n x_k - 2 \sum_{k=1}^n x_k y_k = 0 \end{aligned}$$

We can cancel the factor of 2 from both equations. Then solving for b in the f_b equation and plugging it into the f_m equation, we have

$$\begin{aligned} m \sum_{k=1}^n x_k^2 + \frac{1}{n} \left(\sum_{k=1}^n y_k - m \sum_{k=1}^n x_k \right) \sum_{k=1}^n x_k - \sum_{k=1}^n x_k y_k &= 0 \\ \frac{m}{n} \left(n \sum_{k=1}^n x_k^2 - \left(\sum_{k=1}^n x_k \right)^2 \right) &= \frac{n \sum_{k=1}^n x_k y_k - \sum_{k=1}^n x_k \sum_{k=1}^n y_k}{n} \\ m &= \frac{n \sum_{k=1}^n x_k y_k - \sum_{k=1}^n x_k \sum_{k=1}^n y_k}{n \sum_{k=1}^n x_k^2 - \left(\sum_{k=1}^n x_k \right)^2}. \end{aligned}$$

Plugging this back into the f_b equation and solving for b , we find that

$$b = \frac{1}{n} \left(\sum_{k=1}^n y_k - m \sum_{k=1}^n x_k \right).$$

To verify that these values of b and m produce a minimum, we find the second order partial derivatives

$$f_{bb}(b, m) = 2n \quad f_{bm}(b, m) = f_{mb}(b, m) = 2 \sum_{k=1}^n x_k \quad f_{mm}(b, m) = 2 \sum_{k=1}^n x_k^2.$$

Then for the values of b and m we found above,

$$f_{bb}(b, m) \cdot f_{mm}(b, m) - (f_{bm}(b, m))^2 = 4 \left(n \sum_{k=1}^n x_k^2 - \left(\sum_{k=1}^n x_k \right)^2 \right) > 0,$$

by the Cauchy-Schwarz inequality (you may want to look at Problem 60 in Section 10.4) and $f_{bb}(b, m) = 2n > 0$, so these values of m and b do yield a local minimum. Based on the physical aspects of the problem, the same values of m and b also produce an absolute minimum.

(b) We start by computing the following quantities.

$$\begin{aligned} n &= 5 \\ \sum_{k=1}^5 x_k &= 0 + 1 + 2 + 3 + 4 = 10 \\ \sum_{k=1}^5 y_k &= 2 + 1 + 2 + 4 + 4 = 13 \\ \sum_{k=1}^5 x_k y_k &= 0 + 1 + 4 + 12 + 16 = 33 \\ \sum_{k=1}^5 x_k^2 &= 0 + 1 + 4 + 9 + 16 = 30. \end{aligned}$$

Then

$$\begin{aligned} m &= \frac{5 \cdot 33 - 10 \cdot 13}{5 \cdot 30 - (10)^2} = \frac{7}{10} \\ b &= \frac{1}{5} \left(13 - \frac{7}{10} \cdot 10 \right) = \frac{6}{5}. \end{aligned}$$

This means the line of best fit is

$$y = \frac{7}{10}x + \frac{6}{5}.$$

60. (a) If $\mathbf{u} = \mathbf{v}$, then $u_1 = v_1$ and $u_2 = v_2$ and the second-order directional derivative at (x_0, y_0) is

$$\begin{aligned} D_{\mathbf{u}}g(x_0, y_0) &= u_1^2 f_{xx}(x_0, y_0) + 2u_1 u_2 f_{xy}(x_0, y_0) + u_2^2 f_{yy}(x_0, y_0) \\ &= u_1^2 A + 2u_1 u_2 B + u_2^2 C. \end{aligned}$$

(b) If we take $Au_1^2 + 2Bu_1u_2 + Cu_2^2$ and complete the square, we have

$$\begin{aligned} A \left(u_1^2 + \frac{2Bu_1u_2}{A} \right) + Cu_2^2 &= A \left(u_1 + \frac{Bu_2}{A} \right)^2 + Cu_2^2 - \frac{B^2}{A} u_2^2 \\ &= A \left(u_1 + \frac{Bu_2}{A} \right)^2 + \frac{u_2^2}{A} (AC - B^2). \end{aligned}$$

If $AC - B^2 > 0$ and $A > 0$, then since f_{xx} and $f_{xx}f_{yy} - f_{xy}^2$ are continuous functions, there is a disk B with center (x_0, y_0) with a positive radius $\delta > 0$ where for any point (x, y) in B , both $f_{xx}(x, y) > 0$ and $f_{xx}(x, y)f_{yy}(x, y) - f_{xy}^2(x, y) > 0$. This means that if C is the curve obtained by intersecting the surface of f with the vertical plane through $(x_0, y_0, f(x_0, y_0))$ in the direction of $\mathbf{u}$, then C is concave upward for all such points. Note that this is true for any direction vector $\mathbf{u}$, so the point (x_0, y_0) must be a local minimum. If $AC - B^2 > 0$ and $A < 0$, then, using the same reasoning as above, every curve C will be concave downward inside the disk B in any direction $\mathbf{u}$, so the point (x_0, y_0) must be a local maximum.

If $AC - B^2 < 0$, then there are two cases. If $A \neq 0$, then we claim that $f(x, y)$ takes both positive and negative values, so cannot be a local minimum nor local maximum. Indeed, if $A \neq 0$, then the quadratic equation $Ax^2 + 2Bx + C = 0$ has two distinct real roots, namely $\frac{-B \pm \sqrt{B^2 - AC}}{A}$, and the graph takes both positive and negative values. If $A = 0$, then $B \neq 0$, and the expression $Ax^2 + 2Bx + C = 2Bx + C$ represents a line with a non-zero slope, so takes positive and negative values, as well. In either case, we have that $(0, 0, 0)$ is a saddle point.

(c) Saddle Point Case: Consider the function $f(x, y) = x^3 + y^3$. Then $f_x(x, y) = 3x^2$ and $f_y(x, y) = 3y^2$ so $(0, 0)$ is a critical point. Note that $f_{xx}(x, y) = 6x$, $f_{yy}(x, y) = 6y$, and $f_{xy}(x, y) = 0$, so

$$f_{xx}(0, 0)f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = 0.$$

We can see that $(0, 0)$ is a saddle point since along the curve $y = 0$, then function becomes $f(x, 0) = x^3$ which no matter the disk chosen around the point $(0, 0)$, there will always be points $(a, 0)$ and $(-a, 0)$ for $a > 0$ where $f(-a, 0) \leq f(0, 0) \leq f(a, 0)$ meaning that $(0, 0)$ is a saddle point.

Local Minimum Case: Consider the function $f(x, y) = x^4 + y^4$. Then $f_x(x, y) = 4x^3$ and $f_y(x, y) = 4y^3$ so $(0, 0)$ is a critical point. Note that $f_{xx}(x, y) = 12x^2$, $f_{yy}(x, y) = 12y^2$, and $f_{xy}(x, y) = 0$, so

$$f_{xx}(0, 0)f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = 0.$$

We can see that $(0, 0)$ is a local minimum because it is actually the absolute minimum. Since $x^4, y^4 \geq 0$ for any point (x, y) , this means $f(0, 0) \leq f(x, y)$ for any point (x, y) , so $f(0, 0) = 0$ is the local minimum.

Local Maximum Case: Consider the function $f(x, y) = -x^4 - y^4$. Then $f_x(x, y) = -4x^3$ and $f_y(x, y) = -4y^3$ so $(0, 0)$ is a critical point. Note that $f_{xx}(x, y) = -12x^2$, $f_{yy}(x, y) = -12y^2$, and $f_{xy}(x, y) = 0$, so

$$f_{xx}(0, 0)f_{yy}(0, 0) - [f_{xy}(0, 0)]^2 = 0.$$

We can see that $(0, 0)$ is a local maximum because it is actually the absolute maximum. Since $-x^4, -y^4 \leq 0$ for any point (x, y) , this means $f(0, 0) \geq f(x, y)$ for any point (x, y) , so $f(0, 0) = 0$ is the local maximum.

13.4 Lagrange Multipliers

Concepts and Vocabulary

1. The number λ in the equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ is called a **(c) Lagrange multiplier**.
2. **True**.
3. **False**. Lagrange multipliers can be used for functions with any number of variables. See the discussion preceding Example 5.
4. **False**. The number of Lagrange multipliers depends on the number of constraint functions.

Skill Building

5. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 3 = y\lambda \\ 1 = x\lambda \\ xy - 8 = 0 \end{cases}$$

Eliminating λ from the first two equations results in $y = 3x$, so the third equation becomes

$$\begin{aligned} x(3x) - 8 &= 0 \\ x &= \pm\sqrt{\frac{8}{3}}. \end{aligned}$$

The test points are then $\left(\sqrt{\frac{8}{3}}, 3\sqrt{\frac{8}{3}}\right)$ and $\left(-\sqrt{\frac{8}{3}}, -3\sqrt{\frac{8}{3}}\right)$. The corresponding values are

$$\begin{aligned} f\left(\sqrt{\frac{8}{3}}, 3\sqrt{\frac{8}{3}}\right) &= 4\sqrt{6} \\ f\left(-\sqrt{\frac{8}{3}}, -3\sqrt{\frac{8}{3}}\right) &= -4\sqrt{6} \end{aligned}$$

Then $4\sqrt{6}$ is the maximum value and $-4\sqrt{6}$ is the minimum value.

6. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 3 = \lambda y \\ 1 = \lambda x \\ xy - 1 = 0 \end{cases}$$

Eliminating λ from the first two equations results in $y = 3x$, so the third equation becomes

$$\begin{aligned} x(3x) - 1 &= 0 \\ x &= \pm\sqrt{\frac{1}{3}} = \pm\frac{\sqrt{3}}{3}. \end{aligned}$$

The test points are then $\left(\frac{\sqrt{3}}{3}, \sqrt{3}\right)$ and $\left(-\frac{\sqrt{3}}{3}, -\sqrt{3}\right)$. The corresponding values are

$$\begin{aligned} f\left(\frac{\sqrt{3}}{3}, \sqrt{3}\right) &= 2\sqrt{3} + 4 \\ f\left(-\frac{\sqrt{3}}{3}, -\sqrt{3}\right) &= -2\sqrt{3} + 4 \end{aligned}$$

Then $2\sqrt{3} + 4$ is the maximum value and $-2\sqrt{3} + 4$ is the minimum value.

7. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 3 = 2x\lambda \\ 1 = 8y\lambda \\ x^2 + 4y^2 - 1 = 0 \end{cases}$$

Eliminating λ from the first two equations results in $x = 12y$, so the third equation becomes

$$\begin{aligned} (12y)^2 + 4y^2 - 1 &= 0 \\ y &= \pm \frac{1}{2} \sqrt{\frac{1}{37}} = \pm \frac{\sqrt{37}}{74}. \end{aligned}$$

The test points are then $\left(\frac{6\sqrt{37}}{37}, \frac{\sqrt{37}}{74}\right)$ and $\left(-\frac{6\sqrt{37}}{37}, -\frac{\sqrt{37}}{74}\right)$. The corresponding values are

$$\begin{aligned} f\left(\frac{6\sqrt{37}}{37}, \frac{\sqrt{37}}{74}\right) &= \frac{1}{2}\sqrt{37} + 4 \\ f\left(-\frac{6\sqrt{37}}{37}, -\frac{\sqrt{37}}{74}\right) &= -\frac{1}{2}\sqrt{37} + 4 \end{aligned}$$

Then $\boxed{4 + \frac{1}{2}\sqrt{37} \text{ is the maximum value}}$ and $\boxed{4 - \frac{1}{2}\sqrt{37} \text{ is the minimum value}}$.

8. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 3 = 2x\lambda \\ 1 = 2y\lambda \\ x^2 + y^2 - 4 = 0 \end{cases}$$

Eliminating λ from the first two equations results in $x = 3y$, so the third equation becomes

$$\begin{aligned} (3y)^2 + y^2 - 4 &= 0 \\ y &= \pm \frac{\sqrt{10}}{5}. \end{aligned}$$

The test points are then $\left(\frac{3\sqrt{10}}{5}, \frac{\sqrt{10}}{5}\right)$ and $\left(-\frac{3\sqrt{10}}{5}, -\frac{\sqrt{10}}{5}\right)$. The corresponding values are

$$\begin{aligned} f\left(\frac{3\sqrt{10}}{5}, \frac{\sqrt{10}}{5}\right) &= 2\sqrt{10} \\ f\left(-\frac{3\sqrt{10}}{5}, -\frac{\sqrt{10}}{5}\right) &= -2\sqrt{10} \end{aligned}$$

Then $\boxed{2\sqrt{10} \text{ is the maximum value}}$ and $\boxed{-2\sqrt{10} \text{ is the minimum value}}$.

9. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 1 = 2x\lambda \\ -4y = 2y\lambda \\ x^2 + y^2 - 1 = 0 \end{cases}$$

From the second equation, either $y = 0$, or $\lambda = -2$. If $y = 0$, then the third equation gives us $x = \pm 1$, yielding two test points $(1, 0)$ and $(-1, 0)$. If $\lambda = -2$, then the first equation implies that $x = -\frac{1}{4}$. In this

case, the third equation becomes

$$\begin{aligned}\frac{1}{16} + y^2 - 1 &= 0 \\ y &= \pm \frac{\sqrt{15}}{4},\end{aligned}$$

which yields two more test points $\left(-\frac{1}{4}, \frac{\sqrt{15}}{4}\right)$ and $\left(-\frac{1}{4}, -\frac{\sqrt{15}}{4}\right)$. The corresponding values are

$$\begin{aligned}f(1, 0) &= 1 \\ f(-1, 0) &= -1 \\ f\left(-\frac{1}{4}, \frac{\sqrt{15}}{4}\right) &= -\frac{17}{8} \\ f\left(-\frac{1}{4}, -\frac{\sqrt{15}}{4}\right) &= -\frac{17}{8}\end{aligned}$$

Then 1 is the maximum value and $-\frac{17}{8}$ is the minimum value.

10. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2x = 2x\lambda \\ 12y^2 = 4y\lambda \\ x^2 + 2y^2 - 2 = 0 \end{cases}$$

From the first equation, either $x = 0$, or $\lambda = 1$. If $x = 0$, then the third equation gives us $y = \pm 1$, yielding two test points $(0, 1)$ and $(0, -1)$. If $\lambda = 1$, then the second equation implies that $y = 0$ or $y = \frac{1}{3}$. For $y = 0$, the third equation means $x = \pm\sqrt{2}$ leading to the two test points $(\sqrt{2}, 0)$ and $(-\sqrt{2}, 0)$. For $y = \frac{1}{3}$, the third equation means $x = \pm\frac{4}{3}$ leading to the two test points $\left(\frac{4}{3}, \frac{1}{3}\right)$ and $\left(-\frac{4}{3}, \frac{1}{3}\right)$. The corresponding values are

$$\begin{aligned}f(0, 1) &= 4 \\ f(0, -1) &= -4 \\ f(\sqrt{2}, 0) &= 2 \\ f(-\sqrt{2}, 0) &= 2 \\ f\left(\frac{4}{3}, \frac{1}{3}\right) &= \frac{52}{27} \\ f\left(-\frac{4}{3}, \frac{1}{3}\right) &= \frac{52}{27}\end{aligned}$$

Then 4 is the maximum value and -4 is the minimum value.

11. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2y = 2x\lambda \\ 2x = 2y\lambda \\ x^2 + y^2 - 2 = 0 \end{cases}$$

Eliminating λ from the first two equations, we have $x^2 = y^2$ for $x, y \neq 0$. Notice if either $x = 0$ or $y = 0$, then the other must also be 0 by the first two equations, but then the third equation would not be satisfied.

So neither x nor y can be equal to 0. Plugging $x^2 = y^2$ into the third equation, we find that

$$\begin{aligned}x^2 + x^2 - 2 &= 0 \\x &= \pm 1\end{aligned}$$

These values yield four test points: $(1, 1), (1, -1), (-1, 1), (-1, -1)$. The corresponding values are

$$\begin{aligned}f(1, 1) &= 2 \\f(1, -1) &= -2 \\f(-1, 1) &= -2 \\f(-1, -1) &= 2\end{aligned}$$

Then 2 is the maximum value and -2 is the minimum value.

12. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} y = \lambda 18x \\ x = \lambda 8y \\ 9x^2 + 4y^2 - 36 = 0 \end{cases}$$

Eliminating λ from the first two equations, we have $9x^2 = 4y^2$ for $x, y \neq 0$. Notice if either $x = 0$ or $y = 0$, then the other must also be 0 by the first two equations, but then the third equation would not be satisfied. So neither x nor y can be equal to 0. Plugging $9x^2 = 4y^2$ into the third equation, we find that

$$\begin{aligned}9x^2 + 9x^2 - 36 &= 0 \\x &= \pm\sqrt{2}\end{aligned}$$

Since $y^2 = \frac{9}{4}x^2$, the values for x we found yield four test points:

$\left(\sqrt{2}, \frac{3\sqrt{2}}{2}\right), \left(\sqrt{2}, -\frac{3\sqrt{2}}{2}\right), \left(-\sqrt{2}, \frac{3\sqrt{2}}{2}\right), \left(-\sqrt{2}, -\frac{3\sqrt{2}}{2}\right)$. The corresponding values are

$$\begin{aligned}f\left(\sqrt{2}, \frac{3\sqrt{2}}{2}\right) &= 3 \\f\left(\sqrt{2}, -\frac{3\sqrt{2}}{2}\right) &= -3 \\f\left(-\sqrt{2}, \frac{3\sqrt{2}}{2}\right) &= -3 \\f\left(-\sqrt{2}, -\frac{3\sqrt{2}}{2}\right) &= 3\end{aligned}$$

Then 3 is the maximum value and -3 is the minimum value.

13. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2x - 4y = 2x\lambda \\ -4x + 8y = 2y\lambda \\ x^2 + y^2 - 4 = 0 \end{cases}$$

Eliminating λ from the first two equations, we have

$$\begin{aligned}\frac{2x - 4y}{2x} &= \frac{-4x + 8y}{2y} \\4xy - 8y^2 &= -8x^2 + 16xy \\2x^2 - 5xy - 2y^2 &= 0.\end{aligned}$$

Using the Quadratic Formula with $a = 2$, $b = -5y$, and $c = -2y^2$, we have

$$x = \frac{-(-5y) \pm \sqrt{(-5y)^2 - 4(2)(-2y^2)}}{2(2)} = \frac{5y \pm \sqrt{9y^2}}{4}$$

$$x = 2y \quad \text{or} \quad x = \frac{1}{2}y$$

Plugging $x = 2y$ into the third equation, we have

$$4y^2 + y^2 - 4 = 0$$

$$y = \pm \frac{2}{\sqrt{5}},$$

which yield the two test points $\left(\frac{4}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right)$ and $\left(-\frac{4}{\sqrt{5}}, -\frac{2}{\sqrt{5}}\right)$. Plugging $x = -\frac{1}{2}y$ into the third equation, we have

$$\frac{1}{4}y^2 + y^2 - 4 = 0$$

$$y = \pm \frac{4}{\sqrt{5}},$$

which yield the other two test points $\left(-\frac{2}{\sqrt{5}}, \frac{4}{\sqrt{5}}\right)$ and $\left(\frac{2}{\sqrt{5}}, -\frac{4}{\sqrt{5}}\right)$. The corresponding values are

$$f\left(\frac{4}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right) = 0$$

$$f\left(-\frac{4}{\sqrt{5}}, -\frac{2}{\sqrt{5}}\right) = 0$$

$$f\left(-\frac{2}{\sqrt{5}}, \frac{4}{\sqrt{5}}\right) = 20$$

$$f\left(\frac{2}{\sqrt{5}}, -\frac{4}{\sqrt{5}}\right) = 20$$

Then 20 is the maximum value and 0 is the minimum value.

14. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 18x - 6y = 2x\lambda \\ -6x + 2y = 2y\lambda \\ x^2 + y^2 - 25 = 0 \end{cases}$$

Eliminating λ from the first two equations, we have

$$\frac{18x - 6y}{2x} = \frac{-6x + 2y}{2y}$$

$$36xy - 12y^2 = -12x^2 + 4xy$$

$$3x^2 + 8xy - 3y^2 = 0.$$

Using the Quadratic Formula with $a = 3$, $b = 8y$, and $c = -3y^2$, we have

$$x = \frac{-(8y) \pm \sqrt{(8y)^2 - 4(3)(-3y^2)}}{2(3)} = \frac{-8y \pm \sqrt{100y^2}}{6}$$

$$x = \frac{1}{3}y \quad \text{or} \quad x = -3y$$

Plugging $x = \frac{1}{3}y$ into the third equation, we have

$$\begin{aligned}\frac{1}{9}y^2 + y^2 - 25 &= 0 \\ y &= \pm \frac{3\sqrt{10}}{2},\end{aligned}$$

which yield the two test points $\left(\frac{\sqrt{10}}{2}, \frac{3\sqrt{10}}{2}\right)$ and $\left(-\frac{\sqrt{10}}{2}, -\frac{3\sqrt{10}}{2}\right)$. Plugging $x = -3y$ into the third equation, we have

$$\begin{aligned}9y^2 + y^2 - 25 &= 0 \\ y &= \pm \frac{\sqrt{10}}{2},\end{aligned}$$

which yield the other two test points $\left(-\frac{3\sqrt{10}}{2}, \frac{\sqrt{10}}{2}\right)$ and $\left(\frac{3\sqrt{10}}{2}, -\frac{\sqrt{10}}{2}\right)$. The corresponding values are

$$\begin{aligned}f\left(\frac{\sqrt{10}}{2}, \frac{3\sqrt{10}}{2}\right) &= 0 \\ f\left(-\frac{\sqrt{10}}{2}, -\frac{3\sqrt{10}}{2}\right) &= 0 \\ f\left(-\frac{3\sqrt{10}}{2}, \frac{\sqrt{10}}{2}\right) &= 250 \\ f\left(\frac{3\sqrt{10}}{2}, -\frac{\sqrt{10}}{2}\right) &= 250\end{aligned}$$

Then 250 is the maximum value and 0 is the minimum value.

15. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 4 = 2x\lambda \\ -3 = 2y\lambda \\ 2 = -6\lambda \\ x^2 + y^2 - 6z = 0 \end{cases}$$

From the third equation, we find that $\lambda = -\frac{1}{3}$ so from the first two equations, we have $x = -6$ and $y = \frac{9}{2}$.

Plugging these values into the fourth equation, we find that $z = \frac{75}{8}$ so the only test point is $\left(-6, \frac{9}{2}, \frac{75}{8}\right)$.

The value of the function at this point is

$$f\left(-6, \frac{9}{2}, \frac{75}{8}\right) = -\frac{75}{4}.$$

Since there is only one test point, there is either no maximum or no minimum. Since $\left(0, 0, -\frac{1}{6}\right)$ is on the constraint curve and $f\left(0, 0, -\frac{1}{6}\right) = -\frac{1}{3}$, we know that $-\frac{75}{4}$ is not the maximum. This means there is

no maximum and $-\frac{75}{4}$ is the minimum.

16. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 2x = 2\lambda \\ 4y = -3\lambda \\ 2z = \lambda \\ 2x - 3y + z - 6 = 0 \end{cases}$$

From the first equations, we see that $x = \lambda, y = -\frac{3}{4}\lambda, z = \frac{1}{2}\lambda$. Plugging these into the fourth equation, we have

$$\begin{aligned} 2\lambda + \frac{9}{4}\lambda + \frac{1}{2}\lambda - 6 &= 0 \\ \lambda &= \frac{24}{19}, \end{aligned}$$

which means the only test point is $\left(\frac{24}{19}, -\frac{18}{19}, \frac{12}{19}\right)$. The value of the function at this point is

$$f\left(\frac{24}{19}, -\frac{18}{19}, \frac{12}{19}\right) = \frac{72}{19}.$$

Since there is only one test point, there is either no maximum or no minimum. Since $(0, 0, 6)$ is on the constraint curve and $f(0, 0, 6) = 36$, we know that $\frac{72}{19}$ is not the maximum. This means there is no maximum

and $\frac{72}{19}$ is the minimum.

17. From the Extreme Value Theorem, f has both an absolute maximum and an absolute minimum on the closed, bounded set $x^2 + y^2 \leq 2$. The critical points are the solutions to the system

$$\begin{cases} f_x(x, y) = 2x + 4y = 0 \\ f_y(x, y) = 2y + 4x = 0 \end{cases}$$

Using elimination, the only critical point, $(0, 0)$, lies inside the constraint set. The only other place extrema can occur is on the boundary $g(x, y) = x^2 + y^2 - 2 = 0$. We use Lagrange multipliers to find the extrema of f subject to the constraint curve $g(x, y) = 0$. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2x + 4y = 2x\lambda \\ 2y + 4x = 2y\lambda \\ x^2 + y^2 - 2 = 0 \end{cases}$$

Eliminating λ from the first two equations, we find that

$$\begin{aligned} \frac{2x + 4y}{2x} &= \frac{2y + 4x}{2y} \\ 1 + \frac{2y}{x} &= 1 + \frac{2x}{y} \\ x^2 &= y^2. \end{aligned}$$

Plugging this into the third equation, we have

$$\begin{aligned} x^2 + x^2 - 2 &= 0 \\ x &= \pm 1 \end{aligned}$$

These yield the four test points $(1, 1), (1, -1), (-1, 1), (-1, -1)$. Now we plug the critical points and test

points into f .

$$\begin{aligned} f(0,0) &= 0 \\ f(1,1) &= 6 \\ f(1,-1) &= -2 \\ f(-1,1) &= -2 \\ f(-1,-1) &= 6 \end{aligned}$$

Then 6 is the absolute maximum and -2 is the absolute minimum.

18. From the Extreme Value Theorem, f has both an absolute maximum and an absolute minimum on the closed, bounded set $x^2 + y^2 \leq 4$. The critical points are the solutions to the system

$$\begin{cases} f_x(x, y) = 4x = 0 \\ f_y(x, y) = 2y = 0 \end{cases}$$

The only critical point, $(0,0)$, lies inside the constraint set. The only other place extrema can occur is on the boundary $g(x, y) = x^2 + y^2 - 4 = 0$. We use Lagrange multipliers to find the extrema of f subject to the constraint curve $g(x, y) = 0$. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 4x = 2x\lambda \\ 2y = 2y\lambda \\ x^2 + y^2 - 4 = 0 \end{cases}$$

If $x = 0$, then $y = \pm 2$, so two test points are $(0, 2)$ and $(0, -2)$. If $x \neq 0$, then the first equation implies that $\lambda = 2$ which means, from the second equation, we find that $y = 0$. This means the only other critical points are $(2, 0)$ and $(-2, 0)$. Now we plug the critical points and test points into f .

$$\begin{aligned} f(0,0) &= 0 \\ f(0,2) &= 4 \\ f(0,-2) &= 4 \\ f(2,0) &= 8 \\ f(-2,0) &= 8 \end{aligned}$$

Then 8 is the absolute maximum and 0 is the absolute minimum.

19. We introduce two Lagrange multipliers λ_1 and λ_2 and solve the system

$$\nabla f(x, y, z) = \lambda_1 \nabla g(x, y, z) + \lambda_2 \nabla h(x, y, z), \quad g(x, y, z) = x^2 + y^2 - z^2 = 0, \quad h(x, y, z) = x + y - z + 1 = 0.$$

$$\begin{cases} 2x = \lambda_1 2x + \lambda_2 \\ 2y = \lambda_1 2y + \lambda_2 \\ 2z = -\lambda_1 2z - \lambda_2 \\ x^2 + y^2 - z^2 = 0 \\ x + y - z + 1 = 0 \end{cases}$$

From the first equation, $\lambda_2 = 2x - 2x\lambda_1$, and plugging this into the second equation, we have

$$\begin{aligned} 2y &= 2y\lambda_1 + 2x - 2x\lambda_1 \\ 2y + 2x &= \lambda_1(2y + 2x). \end{aligned}$$

If $x \neq y$, then $\lambda_1 = 1$ which means $\lambda_2 = 0$ from either the first or second equation. The third equation then means that $z = 0$. If $z = 0$, then the final two equations do not have a real solution. So going back, we see that it must be the case that $x = y$. In this case, the final two equations become

$$\begin{cases} 2x^2 - z^2 = 0 \\ 2x - z + 1 = 0 \end{cases}$$

which, using substitution, has solutions $x = -1 + \frac{\sqrt{2}}{2}, z = \sqrt{2} - 1$ and $x = -1 - \frac{\sqrt{2}}{2}, z = -\sqrt{2} - 1$. Then the test points are $\left(-1 + \frac{\sqrt{2}}{2}, -1 + \frac{\sqrt{2}}{2}, \sqrt{2} - 1\right)$ and $\left(-1 - \frac{\sqrt{2}}{2}, -1 - \frac{\sqrt{2}}{2}, -\sqrt{2} - 1\right)$. The corresponding values at the test points are

$$\begin{aligned} f\left(-1 + \frac{\sqrt{2}}{2}, -1 + \frac{\sqrt{2}}{2}, \sqrt{2} - 1\right) &= 6 - 4\sqrt{2} \\ f\left(-1 - \frac{\sqrt{2}}{2}, -1 - \frac{\sqrt{2}}{2}, -\sqrt{2} - 1\right) &= 6 + 4\sqrt{2}. \end{aligned}$$

Then $\boxed{6 + 4\sqrt{2} \text{ is the absolute maximum value}}$ and $\boxed{6 - 4\sqrt{2} \text{ is the absolute minimum value}}$.

20. We introduce two Lagrange multipliers λ_1 and λ_2 and solve the system

$$\nabla w(x, y, z) = \lambda_1 \nabla g(x, y, z) + \lambda_2 \nabla h(x, y, z), \quad g(x, y, z) = 2x + y + 2z - 9 = 0, \quad h(x, y, z) = 5x + 5y + 7z - 29 = 0.$$

$$\begin{cases} 2x = 2\lambda_1 + 5\lambda_2 \\ 2y = \lambda_1 + 5\lambda_2 \\ 2z = 2\lambda_1 + 7\lambda_2 \\ 2x + y + 2z - 9 = 0 \\ 5x + 5y + 7z - 29 = 0 \end{cases}$$

Solving for λ_1 in the second equation and plugging it into the first equation, we have

$$\begin{aligned} 2x &= 2(2y - 5\lambda_2) + 5\lambda_2 \\ \lambda_2 &= \frac{2x - 4y}{-5}. \end{aligned}$$

Plugging this into the third equation (along with λ_1 from the third equation), we have

$$\begin{aligned} 2z &= 2(2y - 5\lambda_2) + 7\lambda_2 \\ 2z &= 4y - 3\lambda_2 \\ 2z &= 4y - 3\left(\frac{2x - 4y}{-5}\right) \\ -3x - 4y + 5z &= 0. \end{aligned}$$

Then using substitution to solve the system including this equation and the last two from the system above, we find the only solution is $(2, 1, 2)$. Then the $\boxed{\text{absolute minimum is } w(2, 1, 2) = 9}$.

Applications and Extensions

21. We will minimize the *square* of the distance between a point (x, y) on the given line and the origin. That is, we will minimize $f(x, y) = x^2 + y^2$ subject to the constraint $g(x, y) = x - 3y - 6 = 0$. We will use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2x = \lambda \\ 2y = -3\lambda \\ x - 3y - 6 = 0 \end{cases}$$

Eliminating λ in the first two equations, we have $y = -3x$. Plugging this into the third equation, we find that

$$x = \frac{3}{5}, \text{ so } y = -\frac{9}{5}. \text{ This means that point } \boxed{\left(\frac{3}{5}, -\frac{9}{5}\right) \text{ is the point closest to the origin on the given line.}}$$

22. We will minimize the *square* of the distance between a point (x, y, z) on the given plane and the origin. That is, we will minimize $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint $g(x, y, z) = 2x + y - 3z - 6 = 0$. We will use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$

and $g(x, y, z) = 0$, namely

$$\begin{cases} 2x = 2\lambda \\ 2y = \lambda \\ 2z = -3\lambda \\ 2x + y - 3z - 6 = 0 \end{cases}$$

Eliminating λ in the first three equations, we have $x = 2y$ and $z = -3y$. Plugging these into the fourth equation, we find that $y = \frac{3}{7}$, so $x = \frac{6}{7}$ and $z = -\frac{9}{7}$. This means that point

$$\left(\frac{6}{7}, \frac{3}{7}, -\frac{9}{7}\right) \text{ is the point closest to the origin on the given plane.}$$

23. We need to minimize $f(x, y) = xy$ subject to the constraint $g(x, y) = x + 2y - 21 = 0$. We will use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} y = \lambda \\ x = 2\lambda \\ x + 2y - 21 = 0 \end{cases}$$

Eliminating λ from the first two equations, we find that $x = 2y$. Plugging this into the third equation, we find that $y = \frac{21}{4}$, so $x = \frac{21}{2}$. The maximum product is $\frac{441}{8}$.

24. We will minimize the quotient $f(x, y) = \frac{x}{y}$ subject to the constraint curve $g(x, y) = 4x + 2y - 100 = 0$. We will use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} \frac{1}{y} = 4\lambda \\ -xy^{-2} = 2\lambda \\ 4x + 2y - 100 = 0 \end{cases}$$

Solving for λ in the first two equations and equating them, we find that

$$\begin{aligned} \frac{1}{4y} &= -\frac{x}{2y^2} \\ 2y^2 &= -4xy \\ y &= -2x. \end{aligned}$$

Plugging this into the third equation, we have that $4x + 2(-2x) - 100 = 0$, which does not have any solutions. This means Lagrange multipliers is not applicable for this problem.

25. (a) To be on the plane $3 - y = 0$, it must be that $y = 3$. So a point on the intersection of the two surfaces must satisfy $g(x, z) = 4x^2 + (3)^2 + z^2 - 16 = 0$. We will minimize the *square* of the distance between a point on this curve and the origin. For such a point $(x, 3, z)$, we seek to minimize $f(x, z) = x^2 + 9 + z^2$ subject to $g(x, z) = 0$. We will use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, z) = \lambda \nabla g(x, z)$ and $g(x, z) = 0$, namely

$$\begin{cases} 2x = 8x\lambda \\ 2z = 2z\lambda \\ 4x^2 + z^2 - 7 = 0 \end{cases}$$

If $z \neq 0$, then the second equation implies that $\lambda = 1$, so that the first equation then yields $x = 0$. If $x = 0$, then from the third equation, we find that $z = \pm\sqrt{7}$ to give us two test points $(0, \sqrt{7}), (0, -\sqrt{7})$.

If $z = 0$, then the third equation gives us $x = \pm\frac{\sqrt{7}}{2}$ which gives two more test points: $(\frac{\sqrt{7}}{2}, 0), (-\frac{\sqrt{7}}{2}, 0)$.

Plugging these into we find that

$$\begin{aligned} f(0, \sqrt{7}) &= 16 \\ f(0, -\sqrt{7}) &= 16 \\ f\left(\frac{\sqrt{7}}{2}, 0\right) &= \frac{43}{4} \\ f\left(\frac{-\sqrt{7}}{2}, 0\right) &= \frac{43}{4} \end{aligned}$$

The points that are farthest from the origin are $\boxed{(0, 3, \sqrt{7}), (0, 3, -\sqrt{7})}$.

(b) The points that are closest to the origin are $\boxed{\left(\frac{\sqrt{7}}{2}, 3, 0\right), \left(-\frac{\sqrt{7}}{2}, 3, 0\right)}$.

26. We will maximize and minimize the *square* of the distance between the origin and the intersection of the surfaces. We want to find the extrema of $f(x, y, z) = x^2 + y^2 + z^2$ subject to $g(x, y, z) = x^2 + 2x + y^2 + z^2 - 16 = 0$ and $h(x, y, z) = 3x + y - z = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda_1 \nabla g(x, y, z) + \lambda_2 \nabla h(x, y, z)$, $g(x, y, z) = 0$, and $h(x, y, z) = 0$, namely

$$\begin{cases} 2x = (2x + 2)\lambda_1 + 3\lambda_2 \\ 2y = 2y\lambda_1 + \lambda_2 \\ 2z = 2z\lambda_1 - \lambda_2 \\ x^2 + 2x + y^2 + z^2 - 16 = 0 \\ 3x + y - z = 0 \end{cases}$$

By adding the second and third equations together, we find that $2y + 2z = \lambda_1(2y + 2z)$, or $y + z = \lambda_1(y + z)$. If $y + z \neq 0$, then $\lambda_1 = 1$. If $\lambda_1 = 1$, then from the first equation, we have $0 = 2 + 3\lambda_2$, or $\lambda_2 = -\frac{2}{3}$. But from the second equation, we find that $\lambda_2 = 0$. So it must be that $\lambda_1 \neq 1$, which means $y + z = 0$, or $y = -z$. Plugging this into the fourth and fifth equations, we have the system

$$\begin{cases} x^2 + 2x + 2y^2 - 16 = 0 \\ 3x + 2y = 0 \end{cases}$$

Solving for x in the second equation and substituting it into the first, we have

$$\begin{aligned} \left(-\frac{2}{3}y\right)^2 + 2\left(-\frac{2}{3}y\right) + 2y^2 - 16 &= 0 \\ \frac{22}{9}y^2 - \frac{4}{3}y - 16 &= 0 \\ 11y^2 - 6y - 72 &= 0 \\ y &= \frac{3 \pm 3\sqrt{89}}{11}. \end{aligned}$$

This means our two test points are

$$\left(\frac{-2 + 2\sqrt{89}}{11}, \frac{3 - 3\sqrt{89}}{11}, \frac{-3 + 3\sqrt{89}}{11}\right) \quad \text{and} \quad \left(\frac{-2 - 2\sqrt{89}}{11}, \frac{3 + 3\sqrt{89}}{11}, \frac{-3 - 3\sqrt{89}}{11}\right).$$

Plugging these point into f , we find the values $\frac{180 - 4\sqrt{89}}{11}$ and $\frac{180 + 4\sqrt{89}}{11}$, respectively. This means that

the point $\boxed{\left(\frac{-2 - 2\sqrt{89}}{11}, \frac{3 + 3\sqrt{89}}{11}, \frac{-3 - 3\sqrt{89}}{11}\right)}$ is farthest from the origin and the point

$$\left(\frac{-2 + 2\sqrt{89}}{11}, \frac{3 - 3\sqrt{89}}{11}, \frac{-3 + 3\sqrt{89}}{11} \right) \text{ is closest to the origin.}$$

27. We use Lagrange multipliers to maximize $f(x, y) = xy$ subject to $g(x, y) = x^2 + 2y^2 - 2 = 0$. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} y = 2x\lambda \\ x = 4y\lambda \\ x^2 + 2y^2 - 2 = 0 \end{cases}$$

Substituting the first equation into the second, we have

$$\begin{aligned} x &= 8x\lambda^2 \\ x = 0 \quad \text{or} \quad \lambda &= \pm \sqrt{\frac{1}{8}} = \pm \frac{\sqrt{2}}{4}. \end{aligned}$$

If $x = 0$, then the first equation says $y = 0$, but the point $(0, 0)$ does not satisfy the third equation so there are no test points in this case. If $\lambda = \pm \frac{\sqrt{2}}{4}$, then the first two equations yield $y^2 = 4x^2\lambda^2 = \frac{1}{2}x^2$. Plugging this into the third equation, we have

$$\begin{aligned} x^2 + x^2 - 2 &= 0 \\ x &= \pm 1. \end{aligned}$$

Using the third equation to find the corresponding y -values, we find that the four test points are then

$$\left(1, \frac{\sqrt{2}}{2}\right), \left(1, -\frac{\sqrt{2}}{2}\right), \left(-1, \frac{\sqrt{2}}{2}\right), \left(-1, -\frac{\sqrt{2}}{2}\right). \text{ The maximum product is then } \frac{\sqrt{2}}{2} \text{ at the points } \left(1, \frac{\sqrt{2}}{2}\right)$$

and $\left(-1, -\frac{\sqrt{2}}{2}\right).$

28. If x, y, z represent the length, width, and height, respectively, for the box, then we look to maximize $V(x, y, z) = xyz$ where $x, y, z > 0$ subject to $SA(x, y, z) = xy + 2xz + 2yz - 48 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla V(x, y, z) = \lambda \nabla SA(x, y, z)$ and $SA(x, y, z) = 0$, namely

$$\begin{cases} yz = \lambda(y + 2z) \\ xz = \lambda(x + 2z) \\ xy = \lambda(2x + 2y) \\ xy + 2xz + 2yz - 48 = 0 \end{cases}$$

Eliminating λ in the first three equations, we have

$$\frac{yz}{y + 2z} = \frac{xz}{x + 2z} = \frac{xy}{2x + 2y}.$$

From the left-most equality, we cross multiply to get that $xyz + 2yz^2 = xyz + 2xz^2$, or $x = y$. Then from the third equation, we have $x^2 = 4x\lambda$, or $x = 4\lambda$. Plugging this into the second equation

$$\begin{aligned} 4\lambda z &= \lambda(4\lambda + 2z) \\ 4z &= 4\lambda + 2z \\ z &= 2\lambda = \frac{1}{2}x = \frac{1}{2}y. \end{aligned}$$

Plugging this all into the fourth equation,

$$\begin{aligned} x^2 + x^2 + x^2 - 48 &= 0 \\ x &= 4, \end{aligned}$$

so $y = 4$ and $z = 2$. The dimensions that maximize the volume are the box with square base and dimensions $\boxed{4 \text{ cm} \times 4 \text{ cm} \times 2 \text{ cm}}$.

29. The surface area of a cylindrical can of radius r and height h is $SA(r, h) = 2\pi r^2 + 2\pi rh$ where $r, h > 0$. We need to maximize this subject to the volume equation $V(r, h) = \pi r^2 h - V = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla SA(r, h) = \lambda \nabla V(r, h)$ and $V(r, h) = 0$, namely

$$\begin{cases} 4\pi r + 2\pi h = 2\pi rh\lambda \\ 2\pi r = \pi r^2\lambda \\ \pi r^2 h - V = 0 \end{cases}$$

From the second equation, $\lambda = \frac{2}{r}$. Plugging this into the first equation, we have

$$\begin{aligned} 4\pi r + 2\pi h &= 4\pi h \\ 2r + h &= 2h \\ 2r &= h. \end{aligned}$$

Then, from the third equation, we have

$$\begin{aligned} 2\pi r^3 &= V \\ r &= \sqrt[3]{\frac{V}{2\pi}}. \end{aligned}$$

If the dimensions of the can are $r = \sqrt[3]{\frac{V}{2\pi}}$ and $h = 2\sqrt[3]{\frac{V}{2\pi}}$, then the surface area will be minimized.

30. If x, y, z represent the length, width, and height, respectively, of the container, then we look to minimize the surface area $SA(x, y, z) = 2(xy + xz + yz)$ subject to the volume being fixed at 216, namely $V(x, y, z) = xyz - 216 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla SA(x, y, z) = \lambda \nabla V(x, y, z)$ and $V(x, y, z) = 0$, namely

$$\begin{cases} 2(y + z) = \lambda yz \\ 2(x + z) = \lambda xz \\ 2(x + y) = \lambda xy \\ xyz - 216 = 0 \end{cases}$$

Eliminating λ in the first three equations, we find that

$$\frac{2(y + z)}{yz} = \frac{2(x + z)}{xz} = \frac{2(x + y)}{xy}.$$

Cross multiplying in the first equality, we have $xyz + xz^2 = xyz + yz^2$, or $x = y$. Similarly, cross multiplying in the second equality results in $y = z$, so $x = y = z$. Plugging these into the fourth equation, we find that $x^3 - 216 = 0$, or $x = 6$, so $x = y = z = 6$. The dimensions that will minimize the amount of material are $\boxed{6 \text{ m} \times 6 \text{ m} \times 6 \text{ m}}$.

31. If x, y, z represent the length, width, and height, respectively, of the box, then the cost function we seek to minimize is $C(x, y, z) = \$1(xy + 2xz + 2yz) = xy + 2xz + 2yz$. Since the volume is fixed at 12, we must have $V(x, y, z) = xyz - 12 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla C(x, y, z) = \lambda \nabla V(x, y, z)$ and $V(x, y, z) = 0$, namely

$$\begin{cases} y + 2z = \lambda yz \\ x + 2z = \lambda xz \\ 2x + 2y = \lambda xy \\ xyz - 12 = 0 \end{cases}$$

Eliminating λ from the first three equations, we have

$$\frac{y + 2z}{yz} = \frac{x + 2z}{xz} = \frac{2x + 2y}{xy}.$$

Cross multiplying the first equality, we have $xyz + 2xz^2 = xyz + 2yz^2$, or $x = y$. Similarly, cross multiplying the second equality, we have $2x^2z + 2xyz = x^2y + 2xyz$, or $y = 2z$. Plugging these into the fourth equation, we have $\frac{1}{2}y^3 - 12 = 0$, or $y = 2\sqrt[3]{3}$. Then the box with square base and dimensions $\boxed{2\sqrt[3]{3} \text{ m} \times 2\sqrt[3]{3} \text{ m} \times \sqrt[3]{3} \text{ m}}$ will minimize the cost of the material.

32. If x, y, z represent the length, width, and height, respectively, of the box, then the cost function we seek to minimize is $C(x, y, z) = \$2xy + \$1(xy + 2xz + 2yz) = 3xy + 2xz + 2yz$ subject to the constraint $V(x, y, z) = xyz - 18 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla C(x, y, z) = \lambda \nabla V(x, y, z)$ and $V(x, y, z) = 0$, namely

$$\begin{cases} 3y + 2z = \lambda yz \\ 3x + 2z = \lambda xz \\ 2x + 2y = \lambda xy \\ xyz - 18 = 0 \end{cases}$$

Eliminating λ from the first three equations, we have

$$\frac{3y + 2z}{yz} = \frac{3x + 2z}{xz} = \frac{2x + 2y}{xy}.$$

Cross multiplying the first equality, we have $3xyz + 2xz^2 = 3xyz + 2yz^2$, or $x = y$. Similarly, cross multiplying the second equality, we have $3x^2y + 2xyz = 2x^2z + 2xyz$, or $z = \frac{3}{2}y$. Plugging these into the fourth equation, we have $\frac{3}{2}y^3 - 18 = 0$, or $y = \sqrt[3]{12}$. Then the box with square base and dimensions

$\boxed{\sqrt[3]{12} \text{ m} \times \sqrt[3]{12} \text{ m} \times \frac{3}{2}\sqrt[3]{12} \text{ m}}$ will minimize the cost of the material.

33. If x, y, z represent the length, width, and height, respectively, of the box, then we look to maximize the volume $V(x, y, z) = xyz$ subject to the constraint $g(x, y, z) = x + y + z - 45 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla V(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} yz = \lambda \\ xz = \lambda \\ xy = \lambda \\ x + y + z - 45 = 0 \end{cases}$$

Eliminating λ from the first three equations, we have $x = y = z$. Plugging this into the fourth equation, we have $3x - 45 = 0$, or $x = 15$. Then the luggage with maximum possible volume is a cube with dimensions $\boxed{15 \text{ in} \times 15 \text{ in} \times 15 \text{ in}}$.

34. We look to maximize $T(x, y, z) = 100x^2yz$ subject to the constraint $g(x, y, z) = x^2 + y^2 + z^2 - 1 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla T(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 200xyz = 2x\lambda \\ 100x^2z = 2y\lambda \\ 100x^2y = 2z\lambda \\ x^2 + y^2 + z^2 - 1 = 0 \end{cases}$$

Subtracting the third equation from the second, we find that $50x^2(z - y) = \lambda(y - z)$. This gives the following possibilities:

(1) $\lambda = x = 0$, so $T = 0$;

(2) $\lambda = -50x^2 \neq 0$, so $y = -z$ from the third equation and $\lambda = 100yz = -100y^2$ from the first, and $x^2 = 2y^2$ from these two λ -values. The last equation then gives $4y^2 = 1$, or $y = \pm \frac{1}{2}$, so we have the test points

$$\left(\pm \frac{\sqrt{2}}{2}, \pm \frac{1}{2}, \mp \frac{1}{2} \right);$$

(3) $\lambda = z = 0$, so $T = 0$;

(4) $y = z \neq 0$, so $\lambda = 50x^2$ from the second equation with $\lambda \neq 0$ (or we again have case (1)), thus $100xy^2 = 50x^3$ from the first equation, or $x^2 = 2y^2$, giving test points $\left(\pm\frac{\sqrt{2}}{2}, \pm\frac{1}{2}, \pm\frac{1}{2}\right)$ just like case (2).

From the test points, we see that T has a maximum of 12.5 degrees Celsius at $\left(\pm\frac{\sqrt{2}}{2}, \frac{1}{2}, \frac{1}{2}\right)$ and $\left(\pm\frac{\sqrt{2}}{2}, -\frac{1}{2}, -\frac{1}{2}\right)$ and a minimum of -12.5 degrees Celsius at $\left(\pm\frac{\sqrt{2}}{2}, \frac{1}{2}, -\frac{1}{2}\right)$ and $\left(\pm\frac{\sqrt{2}}{2}, -\frac{1}{2}, \frac{1}{2}\right)$.

35. (a) The area of the rectangle is $x \cdot 2x = 2x^2$. If the area of the rectangle must be at least 800, then $2x^2 \geq 800$, which means $x \geq 20$ meters. Similarly, if y represents the side length of the square field, then the area of the square is $y \cdot y = y^2$, and the area of the square must be at least 100, so $y^2 \geq 100$, which means $y \geq 10$. To find the maximum value of x , it must occur when y is minimized, namely $y = 10$. The total fencing is 340 meters, so if we add the perimeter of both fields, we find that

$$\begin{aligned} 2(x + 2x) + 4(y) &= 340 \\ x &= \frac{170}{3} - \frac{2}{3}y. \end{aligned}$$

This means the maximum value of x is $x = \frac{170}{3} - \frac{2}{3} \cdot 10 = 50$ meters. Putting both answers together, $20 \leq x \leq 50$.

(b) To maximize enclosed area, we look to maximize $A(x, y) = 2x^2 + y^2$ subject to the fencing constraint $g(x, y) = 6x + 4y - 340 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla A(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 4x = 6\lambda \\ 2y = 4\lambda \\ 6x + 4y - 340 = 0 \end{cases}$$

Eliminating λ from the first two equations, we find that $y = \frac{4}{3}x$. Plugging this into the third equation, we find that $x = 30$, so $y = 40$. The greatest number of square meters that can be enclosed by the two fields is $A(30, 40) = \text{3400 m}^2$. [Answer does not match BoB.]

36. If x and y represent the length and width, respectively, of the garden, then we seek to maximize $A(x, y) = xy$ subject to the constraint $g(x, y) = \$21.53(2x + 2y) - 5000 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla A(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} y = 43.06\lambda \\ x = 43.06\lambda \\ 21.53(2x + 2y) - 5000 = 0 \end{cases}$$

From the first two equations, we see that $x = y$, so from the third equation, we have $x = \frac{500}{4 \cdot 21.53} \approx 58.058$ feet. The largest area that can be enclosed is approximately $A(58.058, 58.058) \approx \text{3370.731 square feet}$.

37. Let $C(x, y) = 18x^2 + 9y^2$ and $g(x, y) = x + y - 5400$. Using Lagrange multipliers, the test points satisfy the system of equations $\nabla C(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 36x = \lambda \\ 18y = \lambda \\ x + y - 5400 = 0 \end{cases}$$

The first two equations imply that $y = 2x$, so plugging this into the third equation, we find that $x = 1800$ which means $y = 3600$. Production levels of $x = 1800$ thousand units and $y = 3600$ thousand units will minimize production cost.

38. Let $P(x, y) = x^2 + 3xy - 6x$ and $g(x, y) = x + y - 40$. Using Lagrange multipliers, the test points satisfy the system of equations $\nabla P(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2x + 3y - 6 = \lambda \\ 3x = \lambda \\ x + y - 40 = 0 \end{cases}$$

The first two equations imply that $x = 3y - 6$, so plugging this into the third equation, we find that $y = \frac{23}{2}$

which means $x = \frac{57}{2}$. The production levels that maximize production are $\boxed{x = \frac{57}{2}}$ and $\boxed{y = \frac{23}{2}}$.

39. (a) Adding the total cost of capital and labor must be \$51,000 which means $g(K, L) = 175K + 125L - 175000 = 0$. We now seek to maximize $P(K, L) = 1.01K^{0.25}L^{0.75}$ subject to the constraint curve g . Using Lagrange multipliers, the test points satisfy the system of equations $\nabla P(K, L) = \lambda \nabla g(K, L)$ and $g(K, L) = 0$, namely

$$\begin{cases} 0.2525K^{-0.75}L^{0.75} = 175\lambda \\ 0.7575K^{0.25}L^{-0.25} = 125\lambda \\ 175K + 125L - 175000 = 0 \end{cases}$$

Eliminating λ in the first two equations, we find that

$$\begin{aligned} \frac{0.2525K^{-0.75}L^{0.75}}{175} &= \frac{0.7575K^{0.25}L^{-0.25}}{125} \\ L &= \frac{132.5625}{31.5625}K. \end{aligned}$$

Plugging this into the third equation, we solve for K and get $K = 250$, which means $L = 1050$. Total production is maximized when units of $\boxed{\text{capital is 250}}$ and units of $\boxed{\text{labor is 1050}}$.

(b) Under these conditions, the maximum number of units of production that could be generated is $P(250, 1050) \approx 740.8$.

40. We will use Lagrange multipliers to minimize and maximize the *square* of the distance between a point (x, y, z) on the two surfaces and the origin. That is, we will minimize and maximize the function $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint curves $g(x, y, z) = xyz + 1 = 0$ and $h(x, y, z) = x + y + z - 1 = 0$. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda_1 \nabla g(x, y, z) + \lambda_2 \nabla h(x, y, z)$, $g(x, y, z) = 0$, and $h(x, y, z) = 0$, namely

$$\begin{cases} 2x = yz\lambda_1 + \lambda_2 \\ 2y = xz\lambda_1 + \lambda_2 \\ 2z = xy\lambda_1 + \lambda_2 \\ xyz + 1 = 0 \\ x + y + z - 1 = 0 \end{cases}$$

Eliminating λ_2 from the first three equations, we have

$$2x - yz\lambda_1 = 2y - xz\lambda_1 = 2z - xy\lambda_1. \quad (13.2)$$

The first equality can be written as

$$2(x - y) = -z\lambda_1(x - y). \quad (13.3)$$

If $x = y$, then the last two equations of the original system become $x^2z + 1 = 0$ and $2x + z - 1 = 0$. Using substitution, we find that $x = 1, z = -1$. This means one test point is $(1, 1, -1)$. Going back to equation (13.3), now we assume $x \neq y$. In this case, $2 = -z\lambda_1$. Plugging this in to the right-most equality in (13.2), we have that $2(y - z) = -\frac{2}{z}x(y - z)$. If $y \neq z$, then $z = -x$ and the last two equations in the original system become $-x^2y + 1 = 0$ and $y - 1 = 0$. The only two solutions here are $y = 1$ and $x = \pm 1$. Since we assumed that $x \neq y$ in this case, the only test point in this case is then $(-1, 1, 1)$. Finally, if $y = z$, then just as above, the last two equations of the original system yield the final test point $(1, -1, 1)$. Each of the test

points $(-1, 1, 1)$, $(1, -1, 1)$, $(1, 1, -1)$ are the same distance from the origin, so they are the points on the two surfaces closest to the origin. However, there is no point that is farther from the origin than all other points.

41. Refer to the solution of Problem 20.

42. Let the fixed surface area of the box be S and the length, width, and height of the box be x, y, z , respectively. We look to maximize $V(x, y, z) = xyz$ subject to $SA(x, y, z) = 2(xy + xz + yz) - S = 0$. Using Lagrange multipliers, the test points satisfy the system of equations $\nabla V(x, y, z) = \lambda \nabla SA(x, y, z)$ and $SA(x, y, z) = 0$, namely

$$\begin{cases} yz = 2(y + z)\lambda \\ xz = 2(x + z)\lambda \\ xy = 2(x + y)\lambda \\ 2(xy + xz + yz) - S = 0 \end{cases}$$

Eliminating λ in the first three equations, we find that

$$\frac{2(y + z)}{yz} = \frac{2(x + z)}{xz} = \frac{2(x + y)}{xy}.$$

Cross multiplying in the first equality, we have $xyz + xz^2 = xyz + yz^2$, or $x = y$. Similarly, cross multiplying in the second equality results in $y = z$, so $x = y = z$. This means the maximum volume of a box with fixed surface area is obtained from a box where the length, width, and height are all the same, namely a cube.

43. If r and h denote the radius and height, respectively, of the cylindrical can and S the fixed surface area, then we look to maximize $V(r, h) = \pi r^2 h$ subject to $SA(r, h) = 2\pi r^2 + 2\pi r h - S = 0$. The test points satisfy the system of equations $\nabla V(r, h) = \lambda \nabla SA(r, h)$ and $SA(r, h) = 0$, namely

$$\begin{cases} 2\pi r h = (4\pi r + 2\pi h)\lambda \\ \pi r^2 = 2\pi r \lambda \\ 2\pi r^2 + 2\pi r h - S = 0 \end{cases}$$

Eliminating λ from the first two equations implies that

$$\begin{aligned} \frac{2\pi r h}{4\pi r + 2\pi h} &= \frac{\pi r^2}{2\pi r} \\ \frac{rh}{2r + h} &= \frac{r}{2} \\ h &= 2r. \end{aligned}$$

So since the only test point occurs when the height is double the radius, we see that the can of maximum volume occurs when the height of the can equals the diameter.

44. We will minimize the *square* of the distance between a point (x, y, z) on the intersection of the surfaces and the origin. That is, we will minimize $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint functions $g(x, y, z) = x + y + z - 1 = 0$ and $h(x, y, z) = x^2 + y^2 - z^2 - 1 = 0$. Using Lagrange multipliers, the test points satisfy the system of equations

$$\begin{cases} 2x = 2x\lambda_1 + \lambda_2 \\ 2y = 2y\lambda_1 + \lambda_2 \\ 2z = -2z\lambda_1 + \lambda_2 \\ x + y + z - 1 = 0 \\ x^2 + y^2 - z^2 - 1 = 0 \end{cases}$$

Eliminating λ_2 from the first three equations, we have

$$x(1 - \lambda_1) = y(1 - \lambda_1) = z(1 + \lambda_1).$$

If $\lambda_1 = 1$, then $z = 0$. In this case, the last two equations become $x + y = 1$ and $x^2 + y^2 = 1$. Solving the first equation for y and plugging it into the second, we have

$$\begin{aligned} x^2 + (1 - x)^2 &= 1 \\ 2x(x - 1) &= 0 \\ x &= 0, 1. \end{aligned}$$

In this case the two test points are $(0, 1, 0)$ and $(1, 0, 0)$.

If $\lambda_1 \neq 1$, then $x = y$ and the last two equations of the original system become $2x + z = 1$ and $2x^2 - z^2 = 1$. Solving the first equation for z and plugging it into the second, we have

$$\begin{aligned} 2x^2 - (1 - 2x)^2 &= 1 \\ -2(x - 1)^2 &= 0 \\ x &= 1. \end{aligned}$$

In this case, the only test point is $(1, 1, -1)$.

The two points closest to the origin are $\boxed{(0, 1, 0)}$ and $\boxed{(1, 0, 0)}$.

45. To be on the union of the two curves means you are one or the other, or both. So we will find the extrema of f on both curves separately and then find the extrema of f by comparing both sets of extrema on both curves.

Let $g(x, y) = x^2 + y^2 - 1 = 0$. To find the extrema of f on the constraint curve $g(x, y) = 0$, we use Lagrange multipliers. The test points satisfy the system of equations

$$\begin{cases} 4x^3 = 2x\lambda \\ 4y^3 = 2y\lambda \\ x^2 + y^2 - 1 = 0 \end{cases}$$

From the first equation, we see that either $x = 0$, or $\lambda = 2x^2$. If $x = 0$, then from the third equation we see that $y = \pm 1$, so two test points are $(0, \pm 1)$. If $x \neq 0$, then $\lambda = 2x^2$ so $\lambda \neq 0$. Plugging this into the second equation, we have $4y^3 = 4yx^2$. From here, either $y = 0$, or $y^2 = x^2$, so $x = \pm y$. If $y = 0$, then from the third equation we see that $x = \pm 1$, so two more test points are $(\pm 1, 0)$. If $x = \pm y$, then from the third equation we see that

$$\begin{aligned} 2y^2 &= 1 \\ y &= \pm \frac{\sqrt{2}}{2}, \end{aligned}$$

which leads to the four test points $\left(\frac{\sqrt{2}}{2}, \pm \frac{\sqrt{2}}{2}\right)$ and $\left(-\frac{\sqrt{2}}{2}, \pm \frac{\sqrt{2}}{2}\right)$.

Now let the constraint curve be $h(x, y) = x^3 + y^3 - 1 = 0$. To find the extrema of f when $h(x, y) = 0$, we use Lagrange multipliers again. The test points satisfy the system of equations

$$\begin{cases} 4x^3 = 3x^2\lambda \\ 4y^3 = 3y^2\lambda \\ x^3 + y^3 - 1 = 0 \end{cases}$$

From the first equation, we see that either $x = 0$, or $\lambda = \frac{4}{3}x$. If $x = 0$, then from the third equation we see that $y = 1$, so one test point is $(0, 1)$. If $x \neq 0$, then $\lambda = \frac{4}{3}x$. Plugging this into the second equation, we find that $4y^3 = 4xy^2$. From here, either $y = 0$, or $x = y$. If $y = 0$, then from the third equation we see that $x = 1$, so another test point is $(1, 0)$. If $x = y$, then the third equation becomes

$$\begin{aligned} 2x^3 &= 1 \\ x &= \frac{1}{\sqrt[3]{2}}, \end{aligned}$$

which leads to the final test point $\left(\frac{1}{\sqrt[3]{2}}, \frac{1}{\sqrt[3]{2}}\right)$.

Plugging each of the test points into $f(x, y)$ we have

$$\begin{aligned} f(\pm 1, 0) = f(0, \pm 1) &= 5 \\ f\left(\frac{\sqrt{2}}{2}, \pm \frac{\sqrt{2}}{2}\right) = f\left(-\frac{\sqrt{2}}{2}, \pm \frac{\sqrt{2}}{2}\right) &= \frac{9}{2} \\ f\left(\frac{1}{\sqrt[3]{2}}, \frac{1}{\sqrt[3]{2}}\right) &= \frac{1}{\sqrt[3]{2}} + 4 \approx 4.794. \end{aligned}$$

Then f attains its maximum value at the points $\left(\frac{\sqrt{2}}{2}, \pm \frac{\sqrt{2}}{2}\right)$ and $\left(-\frac{\sqrt{2}}{2}, \pm \frac{\sqrt{2}}{2}\right)$ and its minimum value at the points $(\pm 1, 0)$ and $(0, \pm 1)$

46. Let $g(x, y, z) = x^2 + y^2 + z^2 - 1$. First note that the extreme values must occur where all of $x, y, z \neq 0$ since the function value at such a point would be 0, however the points $(\pm 1, 0, 0)$ yield values above and below 0, so 0 cannot be an extrema. So for the remainder of the problem, we assume $x, y, z \neq 0$. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} yz = 2x\lambda \\ xz = 2y\lambda \\ xy = 2z\lambda \\ x^2 + y^2 + z^2 - 1 = 0 \end{cases}$$

Eliminating λ from the first three equations, we find that $\frac{yz}{2x} = \frac{xz}{2y} = \frac{xy}{2z}$. Cross multiplying in the first equality, we have $2y^2z = 2x^2z$, or $y = \pm x$. Similarly, the second equality yields $y = \pm z$. Plugging these into the fourth equation, we have

$$\begin{aligned} (\pm y)^2 + y^2 + (\pm y)^2 - 1 &= 0 \\ y &= \pm \frac{\sqrt{3}}{3}. \end{aligned}$$

So $x = \pm \frac{\sqrt{3}}{3}$ and $z = \pm \frac{\sqrt{3}}{3}$.

The maximum value of the product of x, y , and z occurs when their product is positive, and the minimum value occurs when their product is negative. So the

absolute maximum is $\left(\frac{\sqrt{3}}{3}\right)^3 = \frac{\sqrt{3}}{9}$ and the

absolute minimum is $-\left(\frac{\sqrt{3}}{3}\right)^3 = -\frac{\sqrt{3}}{9}$.

Challenge Problems

47. To minimize $f(x, y, z) = x^4 + y^4 + z^4$ subject to the constraint curve $g(x, y, z) = Ax + By + Cz - D = 0$, we use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 4x^3 = \lambda A \\ 4y^3 = \lambda B \\ 4z^3 = \lambda C \\ Ax + By + Cz - D = 0 \end{cases}$$

Solving for λ in the first three equations, we find that

$$\frac{4x^3}{A} = \frac{4y^3}{B} = \frac{4z^3}{C}$$

so that $y = \sqrt[3]{\frac{B}{A}}x$ and $z = \sqrt[3]{\frac{C}{A}}x$. Plugging these into the fourth equation, we have

$$Ax + B \cdot \sqrt[3]{\frac{B}{A}}x + C \cdot \sqrt[3]{\frac{C}{A}}x - D = 0$$

$$x = \frac{A^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}}.$$

Using this value of x to find y and z , we have the single test point

$$\left(\frac{A^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}}, \frac{B^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}}, \frac{C^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}} \right).$$

The minimum value is then

$$f\left(\frac{A^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}}, \frac{B^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}}, \frac{C^{1/3}D}{A^{4/3} + B^{4/3} + C^{4/3}}\right) = \boxed{\frac{D^4}{\left(A^{4/3} + B^{4/3} + C^{4/3}\right)^3}}.$$

48. Consider a triangle inscribed in a circle of radius $R > 0$ with side lengths a, b, c (see the picture below).

Let the central angles corresponding to sides a, b, c be α, β, γ , respectively. Then using the Law of Cosines, we have

$$\begin{aligned} a^2 &= 2R^2 - 2R^2 \cos \alpha = 2R^2 (1 - \cos \alpha) \\ b^2 &= 2R^2 (1 - \cos \beta) \\ c^2 &= 2R^2 (1 - \cos \gamma). \end{aligned}$$

These equations imply that

$$a = \sqrt{2}R(1 - \cos \alpha)^{1/2} \quad a = \sqrt{2}R(1 - \cos \beta)^{1/2} \quad a = \sqrt{2}R(1 - \cos \gamma)^{1/2}.$$

We're looking to minimize

$$P(\alpha, \beta, \gamma) = a + b + c = \sqrt{2}R \left((1 - \cos \alpha)^{1/2} + (1 - \cos \beta)^{1/2} + (1 - \cos \gamma)^{1/2} \right),$$

subject to the constraint $g(\alpha, \beta, \gamma) = \alpha + \beta + \gamma - 2\pi = 0$. Throughout the remainder of the problem, we also assume that $\alpha, \beta, \gamma > 0$. Using Lagrange multipliers, the test points satisfy the system of equations $\nabla P(\alpha, \beta, \gamma) = \lambda \nabla g(\alpha, \beta, \gamma)$ and $g(\alpha, \beta, \gamma) = 0$, namely

$$\begin{cases} \frac{\sqrt{2}}{2}R(1 - \cos \alpha)^{-1/2} \cdot \sin \alpha = \lambda \\ \frac{\sqrt{2}}{2}R(1 - \cos \beta)^{-1/2} \cdot \sin \beta = \lambda \\ \frac{\sqrt{2}}{2}R(1 - \cos \gamma)^{-1/2} \cdot \sin \gamma = \lambda \\ \alpha + \beta + \gamma - 2\pi = 0 \end{cases}$$

Eliminating λ in the first three equations, we have

$$\begin{aligned}\frac{\sin \alpha}{\sqrt{1 - \cos \alpha}} &= \frac{\sin \beta}{\sqrt{1 - \cos \beta}} = \frac{\sin \gamma}{\sqrt{1 - \cos \gamma}} \\ \frac{\sin^2 \alpha}{1 - \cos \alpha} &= \frac{\sin^2 \beta}{1 - \cos \beta} = \frac{\sin^2 \gamma}{1 - \cos \gamma} \\ \frac{1 - \cos^2 \alpha}{1 - \cos \alpha} &= \frac{1 - \cos^2 \beta}{1 - \cos \beta} = \frac{1 - \cos^2 \gamma}{1 - \cos \gamma} \\ 1 + \cos \alpha &= 1 + \cos \beta = 1 + \cos \gamma \\ \cos \alpha &= \cos \beta = \cos \gamma \\ \alpha &= \beta = \gamma.\end{aligned}$$

Since all the inscribed angles are equal, it must be that $a = b = c$, which means the triangle with maximum perimeter is an equilateral triangle.

49. To find the point closest to the paraboloid, we will minimize the *square* of the distance between a point on the paraboloid and $(1, 1, 2)$. For a point (x, y, z) on the paraboloid, the square of the distance between itself at $(1, 1, 2)$ is

$$f(x, y, z) = (x - 1)^2 + (y - 1)^2 + (z - 2)^2.$$

We need to minimize f subject to $g(x, y, z) = x^2 + y^2 + z - 2 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 2(x - 1) = 2x\lambda \\ 2(y - 1) = 2y\lambda \\ 2(z - 2) = \lambda \\ x^2 + y^2 + z - 2 = 0 \end{cases}$$

Solving for λ in the first three equations, we find that

$$\frac{2x - 2}{2x} = \frac{2y - 2}{2y} = 2z - 4$$

so that $y = x$ and $z = \frac{10x - 2}{4x}$. Plugging these into the fourth equation, we find that

$$\begin{aligned}x^2 + x^2 + \frac{10x - 2}{4x} - 2 &= 0 \\ 4x^3 + x - 1 &= 0 \\ (2x - 1)(2x^2 + x + 1) &= 0\end{aligned}$$

for which the only real solution is $x = \frac{1}{2}$. The only test point is then $\left(\frac{1}{2}, \frac{1}{2}, \frac{3}{2}\right)$, making it the minimum based on the physical properties of the problem.

50. To find the point closest to the origin, we will minimize the *square* of the distance between a point on the surface and the origin. For a point (x, y, z) on the curve, the square of the distance between itself and the origin is

$$f(x, y, z) = x^2 + y^2 + z^2.$$

We need to minimize f subject to $g(x, y, z) = xy - z^2 - 6y + 36 = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 2x = y\lambda \\ 2y = (x - 6)\lambda \\ 2z = -2z\lambda \\ xy - z^2 - 6y + 36 = 0 \end{cases}$$

Case 1 $z \neq 0$: From the third equation, if $z \neq 0$, then $\lambda = -1$. In this case, the first two equations become $2x = -y$ and $2y = 6 - x$. Using substitution the solution to this system is $x = -2, y = 4$. Plugging these values into the fourth equation, we find that $z = \pm 2$. Both points $\boxed{(-2, 4, 2)}$ and $\boxed{(-2, 4, -2)}$ have the same distance from the origin, namely $2\sqrt{6}$.

Case 2 $z = 0$: From the last equation, it must be that $xy - 6y + 36 = 0$. Writing this equation as $y = \frac{36}{6-x}$. To find the minimum distance between a point on this hyperbola and the origin (since $z = 0$), we need to minimize $x^2 + y^2 = x^2 + \left(\frac{36}{6-x}\right)^2$. Setting the derivative equal to 0 reduces to the quartic equation $x(x-6)^3 = (36)^2$. Using a CAS (or calculator), we find that $x \approx -2.2817$ and $x \approx 10.915$. The corresponding points are then approximately $(-2.2817, 4.347, 0)$ and $(10.915, -7.324, 0)$, which are farther from the origin than those in case 1.

This means the points $\boxed{(-2, 4, \pm 2)}$ are a minimum distance on the surface to the origin.

Chapter Review

1. Since

$$f_x(x, y) = \frac{1}{\sec(x^2 + y^2)} \cdot \sec(x^2 + y^2) \tan(x^2 + y^2) \cdot 2x = 2x \tan(x^2 + y^2)$$

$$f_y(x, y) = \frac{1}{\sec(x^2 + y^2)} \cdot \sec(x^2 + y^2) \tan(x^2 + y^2) \cdot 2y = 2y \tan(x^2 + y^2)$$

the gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = 2x \tan(x^2 + y^2)\mathbf{i} + 2y \tan(x^2 + y^2)\mathbf{j}.$$

The gradient of f at the point $\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right)$ is

$$\boxed{\nabla f\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right) = \sqrt{\frac{\pi}{2}}\mathbf{i} + \sqrt{\frac{\pi}{2}}\mathbf{j}}.$$

The unit vector in the direction of $\mathbf{a} = \mathbf{i} + \mathbf{j}$ is $\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}$, so the directional derivative of f at the given point in the direction of $\mathbf{a}$ is

$$D_{\mathbf{u}}f\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right) = \nabla f\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right) \cdot \mathbf{u} = \left(\sqrt{\frac{\pi}{2}}\mathbf{i} + \sqrt{\frac{\pi}{2}}\mathbf{j}\right) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}\right)$$

$$= \frac{\sqrt{\pi}}{2} + \frac{\sqrt{\pi}}{2} = \boxed{\sqrt{\pi}}.$$

2. Since

$$f_x(x, y) = \frac{(x^2 + y^2)(2x) - (x^2 - y^2)(2x)}{(x^2 + y^2)^2} = \frac{4xy^2}{(x^2 + y^2)^2}$$

$$f_y(x, y) = \frac{(x^2 + y^2)(-2y) - (x^2 - y^2)(2y)}{(x^2 + y^2)^2} = -\frac{4x^2y}{(x^2 + y^2)^2}$$

the gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = \frac{4xy^2}{(x^2 + y^2)^2}\mathbf{i} - \frac{4x^2y}{(x^2 + y^2)^2}\mathbf{j}.$$

The gradient of f at the point $(1, 1)$ is

$$\boxed{\nabla f(1, 1) = \mathbf{i} - \mathbf{j}}.$$

The unit vector in the direction of $\mathbf{a} = \mathbf{i} - \mathbf{j}$ is $\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j}$, so the directional derivative of f at the given point in the direction of $\mathbf{a}$ is

$$D_{\mathbf{u}}f(1, 1) = \nabla f(1, 1) \cdot \mathbf{u} = (\mathbf{i} - \mathbf{j}) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j}\right)$$

$$= \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} = \boxed{\sqrt{2}}.$$

3. Since

$$f_x(x, y) = \frac{y}{\sqrt{1 - x^2}}$$

$$f_y(x, y) = \sin^{-1} x$$

the gradient of f at (x, y) is

$$\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j} = \frac{y}{\sqrt{1-x^2}}\mathbf{i} + \sin^{-1}(x)\mathbf{j}.$$

The gradient of f at the point $(0, 1)$ is

$$\boxed{\nabla f(0, 1) = \mathbf{i}}.$$

The unit vector in the direction of $\mathbf{a} = 3\mathbf{i} + \mathbf{j}$ is $\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{3}{\sqrt{10}}\mathbf{i} + \frac{1}{\sqrt{10}}\mathbf{j}$, so the directional derivative of f at the given point in the direction of $\mathbf{a}$ is

$$\begin{aligned} D_{\mathbf{u}}f(0, 1) &= \nabla f(0, 1) \cdot \mathbf{u} = (\mathbf{i}) \cdot \left(\frac{3}{\sqrt{10}}\mathbf{i} + \frac{1}{\sqrt{10}}\mathbf{j} \right) \\ &= \boxed{\frac{3\sqrt{10}}{10}}. \end{aligned}$$

4. Since $f(x, y, z) = \ln x + \ln y + \ln z$ and

$$\begin{aligned} f_x(x, y, z) &= \frac{1}{x} \\ f_y(x, y, z) &= \frac{1}{y} \\ f_z(x, y, z) &= \frac{1}{z} \end{aligned}$$

the gradient of f at (x, y, z) is

$$\nabla f(x, y, z) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = \frac{1}{x}\mathbf{i} + \frac{1}{y}\mathbf{j} + \frac{1}{z}\mathbf{k}.$$

The gradient of f at the point $(1, 1, 3)$ is

$$\boxed{\nabla f(1, 1, 3) = \mathbf{i} + \mathbf{j} + \frac{1}{3}\mathbf{k}}.$$

The unit vector in the direction of $\mathbf{a} = \mathbf{i} + \mathbf{j} + 3\mathbf{k}$ is $\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{1}{\sqrt{11}}\mathbf{i} + \frac{1}{\sqrt{11}}\mathbf{j} + \frac{3}{\sqrt{11}}\mathbf{k}$, so the directional derivative of f at the given point in the direction of $\mathbf{a}$ is

$$\begin{aligned} D_{\mathbf{u}}f(1, 1, 3) &= \nabla f(1, 1, 3) \cdot \mathbf{u} = \left(\mathbf{i} + \mathbf{j} + \frac{1}{3}\mathbf{k} \right) \cdot \left(\frac{1}{\sqrt{11}}\mathbf{i} + \frac{1}{\sqrt{11}}\mathbf{j} + \frac{3}{\sqrt{11}}\mathbf{k} \right) \\ &= \boxed{\frac{3\sqrt{11}}{11}}. \end{aligned}$$

5. Since

$$\begin{aligned} f_x(x, y, z) &= -ye^{-x}(x^2 + y^2 + z^2 + 1) + 2xye^{-x} = ye^{-x}(2x - x^2 - y^2 - z^2 - 1) \\ f_y(x, y, z) &= e^{-x}(x^2 + y^2 + z^2 + 1) + 2y^2e^{-x} = e^{-x}(x^2 + 3y^2 + z^2 + 1) \\ f_z(x, y, z) &= 2zye^{-x} \end{aligned}$$

the gradient of f at (x, y, z) is

$$\nabla f(x, y, z) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = ye^{-x}(2x - x^2 - y^2 - z^2 - 1)\mathbf{i} + e^{-x}(x^2 + 3y^2 + z^2 + 1)\mathbf{j} + 2zye^{-x}\mathbf{k}.$$

The gradient of f at the point $(0, 0, 0)$ is

$$\boxed{\nabla f(0, 0, 0) = \mathbf{j}}.$$

The unit vector in the direction of $\mathbf{a} = 2\mathbf{i} + \mathbf{j} + 2\mathbf{k}$ is $\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = \frac{2}{3}\mathbf{i} + \frac{1}{3}\mathbf{j} + \frac{2}{3}\mathbf{k}$, so the directional derivative of f at the given point in the direction of $\mathbf{a}$ is

$$\begin{aligned} D_{\mathbf{u}}f(0, 0, 0) &= \nabla f(0, 0, 0) \cdot \mathbf{u} = (\mathbf{j}) \cdot \left(\frac{2}{3}\mathbf{i} + \frac{1}{3}\mathbf{j} + \frac{2}{3}\mathbf{k} \right) \\ &= \boxed{\frac{1}{3}}. \end{aligned}$$

6. Since

$$\begin{aligned} f_x(x, y, z) &= 2(2x + y + z) \cdot 2 + yz = 8x + 4y + 4z + yz \\ f_y(x, y, z) &= 2(2x + y + z) + xz = 4x + 2y + 2z + xz \\ f_z(x, y, z) &= 2(2x + y + z) + xy = 4x + 2y + 2z + xy \end{aligned}$$

the gradient of f at (x, y, z) is

$$\nabla f(x, y) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k} = (8x + 4y + 4z + yz)\mathbf{i} + (4x + 2y + 2z + xz)\mathbf{j} + (4x + 2y + 2z + xy)\mathbf{k}.$$

The gradient of f at the point $(1, 1, 1)$ is

$$\boxed{\nabla f(1, 1, 1) = 17\mathbf{i} + 9\mathbf{j} + 9\mathbf{k}}.$$

The unit vector in the direction of $\mathbf{a} = -\mathbf{i} - \mathbf{j} - \mathbf{k}$ is $\mathbf{u} = \frac{\mathbf{a}}{\|\mathbf{a}\|} = -\frac{1}{\sqrt{3}}\mathbf{i} - \frac{1}{\sqrt{3}}\mathbf{j} - \frac{1}{\sqrt{3}}\mathbf{k}$, so the directional derivative of f at the given point in the direction of $\mathbf{a}$ is

$$\begin{aligned} D_{\mathbf{u}}f(1, 1, 1) &= \nabla f(1, 1, 1) \cdot \mathbf{u} = (17\mathbf{i} + 9\mathbf{j} + 9\mathbf{k}) \cdot \left(-\frac{1}{\sqrt{3}}\mathbf{i} - \frac{1}{\sqrt{3}}\mathbf{j} - \frac{1}{\sqrt{3}}\mathbf{k} \right) \\ &= \boxed{-\frac{35\sqrt{3}}{3}}. \end{aligned}$$

7. (a) We recall that the direction in which the directional derivative is maximized is the one in the direction of the gradient at the given point. Also, the maximum value of the directional derivative is the magnitude of the gradient, and the minimum value is the opposite of the magnitude of the gradient. The gradient of f and its value at the given point are

$$\begin{aligned} \nabla f(x, y) &= 2x \sec(x^2 + y^2) \tan(x^2 + y^2)\mathbf{i} + 2y \sec(x^2 + y^2) \tan(x^2 + y^2)\mathbf{j} \\ \nabla f\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right) &= \sqrt{\pi}\mathbf{i} + \sqrt{\pi}\mathbf{j}. \end{aligned}$$

The direction for which the directional derivative is maximized is then $\boxed{\frac{\sqrt{2}}{2}\mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j}}.$

(b) The maximum value of the directional derivative is

$$\left\| \nabla f\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right) \right\| = \sqrt{\pi + \pi} = \boxed{\sqrt{2\pi}}$$

and the minimum value of the directional derivative is

$$-\left\| \nabla f\left(\sqrt{\frac{\pi}{8}}, \sqrt{\frac{\pi}{8}}\right) \right\| = \boxed{-\sqrt{2\pi}}.$$

8. (a) We recall that the direction in which the directional derivative is maximized is the one in the direction of the gradient at the given point. Also, the maximum value of the directional derivative is the magnitude

of the gradient, and the minimum value is the opposite of the magnitude of the gradient. The gradient of f (see Problem 2 above) and its value at the given point are

$$\begin{aligned}\nabla f(x, y) &= \frac{4xy^2}{(x^2 + y^2)^2} \mathbf{i} - \frac{4x^2y}{(x^2 + y^2)^2} \mathbf{j} \\ \nabla f(1, 1) &= \mathbf{i} - \mathbf{j}.\end{aligned}$$

The direction for which the directional derivative is maximized is then $\boxed{\frac{\sqrt{2}}{2} \mathbf{i} - \frac{\sqrt{2}}{2} \mathbf{j}}$.

(b) The maximum value of the directional derivative is

$$\|\nabla f(1, 1)\| = \sqrt{1 + 1} = \boxed{\sqrt{2}}$$

and the minimum value of the directional derivative is

$$-\|\nabla f(1, 1)\| = \boxed{-\sqrt{2}}.$$

9. (a) We recall that the direction in which the directional derivative is maximized is the one in the direction of the gradient at the given point. Also, the maximum value of the directional derivative is the magnitude of the gradient, and the minimum value is the opposite of the magnitude of the gradient. The gradient of f (see Problem 3 above) and its value at the given point are

$$\begin{aligned}\nabla f(x, y) &= \frac{y}{\sqrt{1 - x^2}} \mathbf{i} + \sin^{-1}(x) \mathbf{j} \\ \nabla f(0, 1) &= \mathbf{i}.\end{aligned}$$

The direction for which the directional derivative is maximized is then $\boxed{\mathbf{i}}$.

(b) The maximum value of the directional derivative is

$$\|\nabla f(0, 1)\| = \boxed{1}$$

and the minimum value of the directional derivative is

$$-\|\nabla f(0, 1)\| = \boxed{-1}.$$

10. (a) To use the theorem from this section with $F(x, y, z) = x^2 - y^2 + z^2 - 4 = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 2x & F_x(-1, 1, 2) = -2 \\ F_y(x, y, z) = -2y & F_y(-1, 1, 2) = -2 \\ F_z(x, y, z) = 2z & F_z(-1, 1, 2) = 4 \end{array}$$

Then an equation of the tangent plane is

$$\begin{aligned}-2(x + 1) - 2(y - 1) + 4(z - 2) &= 0 \\ \boxed{-2x - 2y + 4z} &= 8.\end{aligned}$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x + 1}{-2} = \frac{y - 1}{-2} = \frac{z - 2}{4}}.$$

11. (a) To use the theorem from this section with $F(x, y, z) = 2x^2 + y^2 - z = 0$, we begin by finding the partial derivatives of F and their values at the given point.

$$\begin{array}{ll} F_x(x, y, z) = 4x & F_x(1, 0, 2) = 4 \\ F_y(x, y, z) = 2y & F_y(1, 0, 2) = 0 \\ F_z(x, y, z) = -1 & F_z(1, 0, 2) = -1 \end{array}$$

Then an equation of the tangent plane is

$$4(x - 1) + 0(y - 0) - 1(z - 2) = 0$$

$$\boxed{4x - z = 2}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x - 1}{4} = \frac{z - 2}{-1}; y = 0}.$$

12. (a) To use the theorem from this section with $F(x, y, z) = y \sin^{-1} x - z = 0$, we begin by finding the partial derivatives of F and their values at the point $(0, 1, 0)$.

$$\begin{array}{l} F_x(x, y, z) = \frac{y}{\sqrt{1 - x^2}} \\ F_x(0, 1, 0) = 1 \\ F_y(x, y, z) = \sin^{-1} x \\ F_y(0, 1, 0) = 0 \\ F_z(x, y, z) = -1 \\ F_z(0, 1, 0) = -1 \end{array}$$

Then an equation of the tangent plane is

$$(x - 0) + 0(y - 1) - (z - 0) = 0$$

$$\boxed{x - z = 0}.$$

(b) Symmetric equations of the normal line are

$$\boxed{\frac{x}{1} = \frac{z}{-1}; y = 1}.$$

13. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x + y + 6 = 0 \\ f_y(x, y) = x + 2y = 0 \end{cases}$$

From the second equation, $x = -2y$, so substituting this into the first equation, we have

$$\begin{array}{rcl} 2(-2y) + y + 6 & = & 0 \\ y & = & 2. \end{array}$$

The only solution is then $x = -4, y = 2$, so the only critical point is $\boxed{(-4, 2)}$.

14. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3x^2 + 3y = 0 \\ f_y(x, y) = -3y^2 + 3x = 0 \end{cases}$$

From the second equation, $x = y^2$, so substituting this into the first equation, we have

$$\begin{aligned} 3(y^2)^2 + 3y &= 0 \\ y(y^3 + 1) &= 0 \\ y &= 0, -1. \end{aligned}$$

The critical points are then $\boxed{(0, 0)}$ and $\boxed{(1, -1)}$.

15. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = y = 0 \\ f_y(x, y) = x = 0 \end{cases}$$

The only critical point is then $\boxed{(0, 0)}$.

16. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = e^{xy} + xy e^{xy} = 0 \\ f_y(x, y) = x^2 e^{xy} = 0 \end{cases}$$

Since e^{xy} is never equal to 0, the second equation tells us that $x = 0$. From the first equation, we have $1 + xy = 0$, but this cannot hold if $x = 0$. This means there are $\boxed{\text{no critical points}}$.

17. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = \cos x = 0 \\ f_y(x, y) = \cos y = 0 \end{cases}$$

The critical points are then $\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right)$ for any integers m, n . The second-order partial derivatives and their values at the critical points are as follows.

$$\begin{aligned} f_{xx}(x, y) &= -\sin x & f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) &= 1 \text{ if } m \text{ is odd} & f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) &= -1 \text{ if } m \text{ is even} \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & f_{xy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) &= 0 \\ f_{yy}(x, y) &= -\sin y & f_{yy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) &= 1 \text{ if } n \text{ is odd} & f_{yy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) &= -1 \text{ if } n \text{ is even} \end{aligned}$$

If m and n are odd, then

$$f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) \cdot f_{yy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) - \left(f_{xy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right)\right)^2 = 1 > 0$$

and $f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) > 0$ so $\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right)$ is a local minimum. The local minimum is

$$\boxed{f\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) = -2 \text{ for } m \text{ and } n \text{ odd}}.$$

If m and n are even, then

$$f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) \cdot f_{yy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) - \left(f_{xy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right)\right)^2 = 1 > 0$$

and $f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) < 0$ so $\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right)$ is a local maximum. The local maximum is

$$\boxed{f\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) = 2 \text{ for } m \text{ and } n \text{ even}}.$$

If exactly one of m or n is odd and the other is even, then

$$f_{xx}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) \cdot f_{yy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right) - \left(f_{xy}\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi\right)\right)^2 = -1 < 0, \text{ so}$$

$$\boxed{\left(\frac{\pi}{2} + m\pi, \frac{\pi}{2} + n\pi, 0\right) \text{ is a saddle point when exactly one of } m \text{ or } n \text{ is odd}}.$$

18. The critical points are solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x = 0 \\ f_y(x, y) = -9 + 2y = 0 \end{cases}$$

The only critical point is then $\left(0, \frac{9}{2}\right)$. The second-order partial derivatives and their values at the critical point are as follows.

$$\begin{aligned} f_{xx}(x, y) &= 2 & A = f_{xx}\left(0, \frac{9}{2}\right) &= 2 \\ f_{xy}(x, y) &= f_{yx}(x, y) = 0 & B = f_{xy}\left(0, \frac{9}{2}\right) &= 0 \\ f_{yy}(x, y) &= 2 & C = f_{yy}\left(0, \frac{9}{2}\right) &= 2 \\ AC - B^2 &= 4 \end{aligned}$$

Since $AC - B^2 > 0$ and $A > 0$, the critical point $\left(0, \frac{9}{2}\right)$ is a local minimum. The local minimum is

$$\boxed{f\left(0, \frac{9}{2}\right) = -\frac{81}{4}}.$$

19. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = 2x - 2y = 0 \\ f_y(x, y) = -2x + 2 = 0 \end{cases}$$

The only critical point is then $(1, 1)$. The value of f at this point is

$$f(1, 1) = 1.$$

The boundary of D is made up of the four line segments L_1 , L_2 , L_3 , and L_4 as drawn in the following picture.

On L_1 : $y = 0$ and $0 \leq x \leq 3$. The function $f(x, y) = f(x, 0) = x^2$ is increasing on $0 \leq x \leq 3$ and its extreme values are $f(0, 0) = 0$ and $f(3, 0) = 9$.

On L_2 : $x = 3$ and $0 \leq y \leq 4$. The function $f(x, y) = f(3, y) = 9 - 4y$ is decreasing on $0 \leq y \leq 4$ and its extreme values are $f(3, 4) = -7$ and $f(3, 0) = 9$.

On L_3 : $y = 4$ and $0 \leq x \leq 3$. The function $f(x, y) = f(x, 4) = x^2 - 8x + 8$ can be thought of as a function of a single variable, namely $g(x) = x^2 - 8x + 8$. The extrema of this function can be found by finding the critical number(s) of g , namely where $g'(x) = 2x - 8 = 0$, or $x = 4$. Since this value is not in the interval $0 \leq x \leq 3$, the extreme values occur at the endpoints $x = 0$ and $x = 3$. The extreme values of f on L_3 are $g(0) = f(0, 4) = 8$ and $g(3) = f(3, 4) = -7$.

On L_4 : $x = 0$ and $0 \leq y \leq 4$. Then function $f(x, y) = f(0, y) = 2y$ is increasing on $0 \leq y \leq 4$ and its extreme values are $f(0, 0) = 0$ and $f(0, 4) = 8$.

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is -7 and the absolute maximum is 9 .

20. The function f is continuous on its domain, which is a closed, bounded set. To find the absolute extrema, we first find the critical points of f , namely the solutions of the system of equations

$$\begin{cases} f_x(x, y) = 3y^2 = 0 \\ f_y(x, y) = 6xy = 0 \end{cases}$$

From the first equation, we see that $y = 0$, and x can be any value. So $(a, 0)$ is a critical point for any value $-3 \leq a \leq 3$ since the point must lie in D . The value of f at a critical point $(a, 0)$ is $f(a, 0) = 0$.

The boundary of D is a circle of radius 3 centered at the origin which can be parameterized by $x(t) = 3 \cos t$ and $y = 3 \sin t$ for $0 \leq t \leq 2\pi$. On the boundary

$$z = f(x, y) = f(3 \cos t, 3 \sin t) = 81 \cos t \sin^2 t.$$

Now we find where $z'(t) = 0$ on $0 \leq t \leq 2\pi$.

$$\begin{aligned} -81 \sin^3 t + 162 \cos^2 t \sin t &= 0 \\ 81 \sin t (-1 + 3 \cos^2 t) &= 0 \end{aligned}$$

$$t = 0, \pi, 2\pi, \cos^{-1}\left(\frac{\sqrt{3}}{3}\right), \pi - \cos^{-1}\left(\frac{\sqrt{3}}{3}\right).$$

The values of f at these points are

$$\begin{aligned} f(3 \cos 0, 3 \sin 0) &= f(3 \cos \pi, 3 \sin \pi) = f(3 \cos 2\pi, 3 \sin 2\pi) = 0 \\ f\left(3 \cos \cos^{-1}\left(\frac{\sqrt{3}}{3}\right), 3 \sin \cos^{-1}\left(\frac{\sqrt{3}}{3}\right)\right) &= f\left(\sqrt{3}, \frac{\sqrt{6}}{3}\right) = 2\sqrt{3} \\ f\left(3 \cos\left(\pi - \cos^{-1}\left(\frac{\sqrt{3}}{3}\right)\right), 3 \sin\left(\pi - \cos^{-1}\left(\frac{\sqrt{3}}{3}\right)\right)\right) &= f\left(-\sqrt{3}, \frac{\sqrt{6}}{3}\right) = -2\sqrt{3} \end{aligned}$$

Comparing the values of f at the critical points and on the boundary, we see that the absolute minimum is $-2\sqrt{3}$

and the absolute maximum is $2\sqrt{3}$.

21. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 10x + y = 2\lambda \\ 6y + x = -\lambda \\ 2x - y - 20 = 0 \end{cases}$$

Solving for λ in the second equation, and plugging it into the first equation, we have

$$\begin{aligned} 10x + y &= 2(-6y - x) \\ y &= -\frac{12}{13}x. \end{aligned}$$

Plugging this into the third equation, we find that $2x + \frac{12}{13}x - 20 = 0$, or $x = \frac{130}{19}$. The only test point is

then $\left(\frac{130}{19}, -\frac{120}{19}\right)$. The minimum value is $f\left(\frac{130}{19}, -\frac{120}{19}\right) = \frac{5900}{19}$.

22. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} \sqrt{y} = 2\lambda \\ \frac{1}{2}xy^{-1/2} = \lambda \\ 2x + y - 3000 = 0 \end{cases}$$

Solving for λ in the first two equations and equating them yields

$$\begin{aligned} \frac{1}{2}y^{1/2} &= \frac{1}{2}xy^{-1/2} \\ y &= x. \end{aligned}$$

Then the third equation becomes

$$\begin{aligned} 2x + x - 3000 &= 0 \\ x &= 1000. \end{aligned}$$

The only test point is then $(1000, 1000)$. The minimum value is $f(1000, 1000) = 10000\sqrt{10}$.

23. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} 2x = 2\lambda \\ 2y = \lambda \\ 2x + y - 4 = 0 \end{cases}$$

Eliminating λ in the first two equations yields $x = 2y$. Plugging this into the third equation yields $4y + y - 4 = 0$, or $y = \frac{4}{5}$. The only test point is then $\left(\frac{8}{5}, \frac{4}{5}\right)$. The minimum value is $f\left(\frac{8}{5}, \frac{4}{5}\right) = \frac{16}{5}$.

24. The test points satisfy the system of equations $\nabla f(x, y) = \lambda \nabla g(x, y)$ and $g(x, y) = 0$, namely

$$\begin{cases} y^2 = 2x\lambda \\ 2xy = 2y\lambda \\ x^2 + y^2 - 1 = 0 \end{cases}$$

From the second equation, we see that $2y(x - \lambda) = 0$, so that either $y = 0$, or $x = \lambda$. If $y = 0$, then the third equation implies that $x = \pm 1$, so two test points are $(1, 0)$ and $(-1, 0)$. If $x = \lambda$, then the first equation says that $y^2 = 2x^2$. Plugging this into the third equation, we find that $x^2 + 2x^2 - 1 = 0$, or $x = \pm \frac{\sqrt{3}}{3}$. Then using $y^2 = 2x^2$, we find the four test points

$$\left(\frac{\sqrt{3}}{3}, \frac{\sqrt{6}}{3}\right), \left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{6}}{3}\right), \left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{6}}{3}\right), \left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{6}}{3}\right).$$

The corresponding values are

$$\begin{aligned} f(1, 0) &= f(-1, 0) &= 0 \\ f\left(\frac{\sqrt{3}}{3}, \frac{\sqrt{6}}{3}\right) &= f\left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{6}}{3}\right) &= \frac{2\sqrt{3}}{9} \\ f\left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{6}}{3}\right) &= f\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{6}}{3}\right) &= -\frac{2\sqrt{3}}{9} \end{aligned}$$

Then $-\frac{2\sqrt{3}}{9}$ is the minimum value and $\frac{2\sqrt{3}}{9}$ is the maximum value.

25. (a) The rate of change in temperature at $(0, 0)$ is $D_{\mathbf{u}}T(0, 0)$ where $\mathbf{u}$ is the unit vector in the direction of $4\mathbf{i} + 3\mathbf{j}$. That is, $\mathbf{u} = \frac{4}{5}\mathbf{i} + \frac{3}{5}\mathbf{j}$. To compute the directional derivative, we first compute the gradient of T .

$$\begin{aligned} T_x(x, y) &= e^y(\sin x + \sin y) + e^y(\cos x) \\ T_y(x, y) &= e^y \cos y, \end{aligned}$$

so

$$\nabla T(x, y) = (e^y(\sin x + \sin y) + e^y(\cos x))\mathbf{i} + e^y \cos y \mathbf{j}.$$

Then

$$\begin{aligned} D_{\mathbf{u}}T(0, 0) &= \nabla T(0, 0) \cdot \mathbf{u} = (\mathbf{i} + \mathbf{j}) \cdot \left(\frac{4}{5}\mathbf{i} + \frac{3}{5}\mathbf{j}\right) \\ &= \frac{7}{5}. \end{aligned}$$

The rate of change in temperature at $(0, 0)$ in the direction of $4\mathbf{i} + 3\mathbf{j}$ is $\frac{7}{5}^\circ\text{C}$.

(b) The greatest temperature increase at $(0, 0)$ occurs in the direction of the gradient at $(0, 0)$, namely

$$\nabla T(0, 0) = \mathbf{i} + \mathbf{j},$$

which is the same direction as the unit vector $\mathbf{u} = \frac{\sqrt{2}}{2}\mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j}$.

(c) The greatest temperature decrease at $(0, 0)$ occurs in the opposite direction of the gradient at $(0, 0)$, namely

$$-\nabla T(0, 0) = -\mathbf{i} - \mathbf{j},$$

which is the same direction as the unit vector $-\mathbf{u} = -\frac{\sqrt{2}}{2}\mathbf{i} - \frac{\sqrt{2}}{2}\mathbf{j}$.

(d) The rate of change in T at $(0, 0)$ remains the same for directions orthogonal to the gradient $\nabla T(0, 0) = \mathbf{i} + \mathbf{j}$. Those two directions are $\pm(\mathbf{i} - \mathbf{j})$, which are the same directions as the unit vectors $\pm\left(\frac{\sqrt{2}}{2}\mathbf{i} - \frac{\sqrt{2}}{2}\mathbf{j}\right)$.

26. (a) The profit function $P(x, y) = R(x, y) - C(x, y)$ is

$$P(x, y) = -3x^2 - 2y^2 + 2xy + 1800x.$$

The critical points are solutions of the system of equations

$$\begin{cases} P_x(x, y) = -6x + 2y + 1800 = 0 \\ f_y(x, y) = -4y + 2x = 0 \end{cases}$$

From the last equation, we see that $x = 2y$, so plugging this into the first equation, we have

$$\begin{aligned} -6(2y) + 2y + 1800 &= 0 \\ y &= 180, \end{aligned}$$

so $x = 360$. The second-order partial derivatives and their values at $(360, 180)$ are as follows.

$$\begin{aligned} P_{xx}(x, y) &= -6 & A &= P_{xx}(360, 180) = -6 \\ P_{xy}(x, y) &= P_{yx}(x, y) = 2 & B &= P_{xy}(360, 180) = 2 \\ P_{yy}(x, y) &= -4 & C &= P_{yy}(360, 180) = -4 \\ AC - B^2 &= 20 \end{aligned}$$

Since $AC - B^2 > 0$ and $A < 0$, the point $(360, 180)$ is a local maximum, which is then the absolute maximum based on the nature of the problem. When the number of units of $x = 360$ and the number of units of $y = 180$ the profit will be maximized.

(b) The maximum profit is $P(360, 180) = 324000$.

27. (a) Adding the total value of capital and labor must be \$51,000 which means $g(K, L) = 50K + 100L - 51000 = 0$. We now seek to maximize $P(K, L) = 10K^{0.3}L^{0.7}$ subject to the constraint curve g . Using Lagrange multipliers, the test points satisfy the system of equations $\nabla P(K, L) = \lambda \nabla g(K, L)$ and $g(K, L) = 0$, namely

$$\begin{cases} 3K^{-0.7}L^{0.7} = 50\lambda \\ 7K^{0.3}L^{-0.3} = 100\lambda \\ 50K + 100L - 51000 = 0 \end{cases}$$

Solving for λ in the first two equations and equating them, we have

$$\begin{aligned} \frac{3L^{0.7}}{50K^{0.7}} &= \frac{7K^{0.3}}{100L^{0.3}} \\ L &= \frac{7}{6}K. \end{aligned}$$

Plugging this into the third equation, we solve for K and get $K = 306$, which means $L = 357$. Total production is maximized when units of capital is 306 and units of labor is 357.

(b) Under these conditions, the maximum number of units of production that could be generated is $P(306, 357)$ ≈ 3408.7 .

28. If (x, y, z) is some point on the given surface that is also a vertex of the rectangular solid where each of $x, y, z > 0$, then the other eight vertices of the solid are $(\pm x, \pm y, \pm z)$. This means the length of the solid is $2x$, the width is $2y$, and the height is $2z$. So we are trying to maximize $f(x, y, z) = 8xyz$ subject to the constraint that $g(x, y, z) = \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} - 1 = 0$. Using Lagrange multipliers, the test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 8yz = \frac{2x}{a^2}\lambda \\ 8xz = \frac{2y}{b^2}\lambda \\ 8xy = \frac{2z}{c^2}\lambda \\ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} - 1 = 0 \end{cases}$$

Eliminating λ from the first three equations, we find that

$$\begin{aligned} \frac{8yza^2}{2x} &= \frac{8xzb^2}{2y} = \frac{8xyc^2}{2z} \\ \frac{yza^2}{x} &= \frac{xzb^2}{y} = \frac{xyz^2}{z} \end{aligned}$$

Cross multiplying in the first equality, we have $y^2za^2 = x^2zb^2$, or $x = \frac{a}{b}y$ since $x, y > 0$. Similarly, the second equality yields $z = \frac{c}{b}y$. Plugging these into the fourth equation, we have

$$\begin{aligned} \frac{\frac{a^2}{b^2}y^2}{a^2} + \frac{y^2}{b^2} + \frac{\frac{c^2}{b^2}y^2}{c^2} - 1 &= 0 \\ \frac{3y^2}{b^2} &= 1 \\ y &= \frac{b}{\sqrt{3}}. \end{aligned}$$

So $x = \frac{a}{\sqrt{3}}$ and $z = \frac{c}{\sqrt{3}}$.

The maximum volume is then $f\left(\frac{a}{\sqrt{3}}, \frac{b}{\sqrt{3}}, \frac{c}{\sqrt{3}}\right) = \frac{8}{3\sqrt{3}}abc$.

29. We will use Lagrange multipliers to minimize the *square* of the distance between a point (x, y, z) on the surface and the origin. That is, we will minimize the function $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint curve $g(x, y, z) = xyz - 1 = 0$. The test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$, $g(x, y, z) = 0$, namely

$$\begin{cases} 2x = yz\lambda \\ 2y = xz\lambda \\ 2z = xy\lambda \\ xyz - 1 = 0 \end{cases}$$

Noting that $x, y, z \neq 0$ for otherwise the fourth equation could never hold, we solve for λ in the first three equations and equate them

$$\frac{2x}{yz} = \frac{2y}{xz} = \frac{2z}{xy}.$$

Cross multiplying the first equality results in $2x^2z = 2y^2z$, or $x = \pm y$. Similarly, the second equality yields $z = \pm y$. Plugging these into the fourth equation, we find that $(\pm y) \cdot y \cdot (\pm y) = 1$, or $\pm y^3 = 1$. This equation can only hold if $y = \pm 1$. This means the points on the surface closest to the origin are

$$\boxed{(1, 1, 1), (-1, 1, -1), (-1, -1, 1), (1, -1, -1)}.$$

[Note, for example, that the point $(1, 1, -1)$ is not one of the points since this point is not on the surface $xyz = 1$.]

30. Let (x, y, z) be the point on the plane that is also the vertex of the rectangular solid where $x, y, z > 0$. The volume of the rectangular solid is then $f(x, y, z) = xyz$. So we are trying to maximize $f(x, y, z) = xyz$ subject to the constraint that $g(x, y, z) = \frac{x}{a} + \frac{y}{b} + \frac{z}{c} - 1 = 0$. Using Lagrange multipliers, the test points satisfy the system of equations $\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} yz = \frac{1}{a}\lambda \\ xz = \frac{1}{b}\lambda \\ xy = \frac{1}{c}\lambda \\ \frac{x}{a} + \frac{y}{b} + \frac{z}{c} - 1 = 0 \end{cases}$$

Eliminating λ from the first three equations, we find that $ayz = bxz = cxy$. In the first equality, we have $x = \frac{a}{b}y$ since $x, y > 0$. Similarly, the second equality yields $z = \frac{c}{b}y$. Plugging these into the fourth equation, we have

$$\begin{aligned} \frac{\frac{a}{b}y}{a} + \frac{y}{b} + \frac{\frac{c}{b}y}{c} - 1 &= 0 \\ \frac{3y}{b} &= 1 \\ y &= \frac{b}{3}. \end{aligned}$$

So $x = \frac{a}{3}$ and $z = \frac{c}{3}$.

The maximum volume is then $f\left(\frac{a}{3}, \frac{b}{3}, \frac{c}{3}\right) = \boxed{\frac{abc}{27}}$.

31. If x, y, z represent the length, width, and height, respectively, of the box, then the cost function we seek to minimize is $C(x, y, z) = 5xy + 1 \cdot (xy + 2xz + 2yz) = 6xy + 2xz + 2yz$ subject to the constraint $g(x, y, z) = xyz - V = 0$. We use Lagrange multipliers. The test points satisfy the system of equations $\nabla C(x, y, z) = \lambda \nabla g(x, y, z)$ and $g(x, y, z) = 0$, namely

$$\begin{cases} 6y + 2z = \lambda yz \\ 6x + 2z = \lambda xz \\ 2x + 2y = \lambda xy \\ xyz - V = 0 \end{cases}$$

Eliminating λ from the first three equations, we have

$$\frac{6y + 2z}{yz} = \frac{6x + 2z}{xz} = \frac{2x + 2y}{xy}.$$

Cross multiplying the first equality, we have $6xyz + 2xz^2 = 6xyz + 2yz^2$, or $x = y$. Similarly, cross multiplying the second equality, we have $6x^2y + 2xyz = 2x^2z + 2xyz$, or $z = 3y$. Plugging these into the fourth equation,

we have $3y^3 - V = 0$, or $y = \sqrt[3]{\frac{V}{3}}$. Then the box with square base and dimensions $\sqrt[3]{\frac{V}{3}} \times \sqrt[3]{\frac{V}{3}} \times 3\sqrt[3]{\frac{V}{3}}$ will minimize the cost of the material.

32. We introduce two Lagrange multipliers λ_1 and λ_2 and solve the system

$$\nabla f(x, y, z) = \lambda_1 \nabla g(x, y, z) + \lambda_2 \nabla h(x, y, z), \quad g(x, y, z) = x^2 + y^2 - 1 = 0, \quad h(x, y, z) = y - 3z = 0.$$

$$\begin{cases} yz = 2x\lambda_1 \\ xz = 2y\lambda_1 + \lambda_2 \\ xy = -3\lambda_2 \\ x^2 + y^2 - 1 = 0 \\ y - 3z = 0 \end{cases}$$

If $x = 0$, then from the fourth equation, we see that $y = \pm 1$ and then from the first equation, we see that $z = 0$. But this cannot be since $y = 3z$ from the fifth equation. This means $x \neq 0$. Solving for λ_1 in the first equation and λ_2 in the third equation, and plugging them into the second equation, we have

$$\begin{aligned} xz &= 2y \left(\frac{yz}{2x} \right) - \frac{xy}{3} \\ x^2 z &= y^2 z - \frac{x^2 y}{3} \\ x^2 z &= 9z^3 - x^2 z && \text{using } y = 3z \text{ from the fifth equation} \\ z(2x^2 - 9z^2) &= 0. \end{aligned}$$

If $z = 0$, then $y = 0$ too from equation five, which means $x = \pm 1$ from the fourth equation. So two test points are $(\pm 1, 0, 0)$. Now if $z \neq 0$, then it must be that $2x^2 = 9z^2$, or $z = \pm \frac{\sqrt{2}}{3}x$. From the fifth equation, $y = 3z = \pm\sqrt{2}x$. Plugging $y = \pm\sqrt{2}x$ into the fourth equation, we have

$$\begin{aligned} x^2 + \left(\pm\sqrt{2}x \right)^2 &= 1 \\ 3x^2 &= 1 \\ x &= \pm \frac{1}{\sqrt{3}}. \end{aligned}$$

This gives us four more test points

$$\left(\frac{1}{\sqrt{3}}, \frac{\sqrt{2}}{\sqrt{3}}, \frac{\sqrt{6}}{9} \right), \left(\frac{1}{\sqrt{3}}, -\frac{\sqrt{2}}{\sqrt{3}}, -\frac{\sqrt{6}}{9} \right), \left(-\frac{1}{\sqrt{3}}, \frac{\sqrt{2}}{\sqrt{3}}, \frac{\sqrt{6}}{9} \right), \left(-\frac{1}{\sqrt{3}}, -\frac{\sqrt{2}}{\sqrt{3}}, -\frac{\sqrt{6}}{9} \right).$$

Plugging each of the test points into f , we find that

$$\begin{aligned} f(1, 0, 0) &= f(-1, 0, 0) = 0 \\ f\left(\frac{1}{\sqrt{3}}, \frac{\sqrt{2}}{\sqrt{3}}, \frac{\sqrt{6}}{9}\right) &= f\left(\frac{1}{\sqrt{3}}, -\frac{\sqrt{2}}{\sqrt{3}}, -\frac{\sqrt{6}}{9}\right) = \frac{2\sqrt{3}}{27} \\ f\left(-\frac{1}{\sqrt{3}}, \frac{\sqrt{2}}{\sqrt{3}}, \frac{\sqrt{6}}{9}\right) &= f\left(-\frac{1}{\sqrt{3}}, -\frac{\sqrt{2}}{\sqrt{3}}, -\frac{\sqrt{6}}{9}\right) = -\frac{2\sqrt{3}}{27} \end{aligned}$$

Then $\frac{2\sqrt{3}}{27}$ is the absolute maximum and $-\frac{2\sqrt{3}}{27}$ is the absolute minimum.

Multiple Integrals

14.1 The Double Integral over a Rectangular Region

Concepts and Vocabulary

1. True. First, we integrate partially with respect to y ; since x is treated as a constant with respect to y , by properties of definite integrals we can factor it out:

$$\int_0^2 \left[\int_0^1 xy^2 dy \right] dx = \int_0^2 x \left[\int_0^1 y^2 dy \right] dx.$$

Now in the integral with respect to x , the value of $\left[\int_0^1 y^2 dy \right]$ is a numerical constant, which can be factored out, yielding

$$\int_0^2 x \left[\int_0^1 y^2 dy \right] dx = \left[\int_0^2 x dx \right] \cdot \left[\int_0^1 y^2 dy \right].$$

2. False. If a function f is continuous on a closed rectangular region R defined by $a \leq x \leq b$ and $c \leq y \leq d$, then according to Fubini's Theorem: $\int_c^d \left[\int_a^b f(x, y) dx \right] dy = \int_a^b \left[\int_c^d f(x, y) dy \right] dx$.
3. $\int_1^4 x^2 \sqrt{y} dy$ is a partial integral with respect to y , whose output is (d) a function of x .
4. True. According to the Existence of the Double Integral Theorem, for a function $z = f(x, y)$ that is continuous on a closed rectangular region R , the double integral $\iint_R f(x, y) dA$ exists.

Skill Building

5. Let $f(x, y) = x(3 - y)$, and let R be the closed rectangular region defined by $0 \leq x \leq 3$, $0 \leq y \leq 3$. Partition R into nine congruent subsquares with sides $\Delta x_i = 1$, $i = 1, 2, 3$, and $\Delta y_j = 1$, $j = 1, 2, 3$, each with area $\Delta A_k = 1$, as shown in the figure in Problem 5.
 - (a) Choose (u_k, v_k) , $k = 1, 2, \dots, 9$, as the lower right corner of the k th subsquare: $(u_1, v_1) = (1, 0)$, $(u_2, v_2) = (2, 0)$, $(u_3, v_3) = (3, 0)$, $(u_4, v_4) = (1, 1)$, $(u_5, v_5) = (2, 1)$, $(u_6, v_6) = (3, 1)$, $(u_7, v_7) = (1, 2)$, $(u_8, v_8) = (2, 2)$, and $(u_9, v_9) = (3, 2)$. Then the corresponding Riemann sum is:

$$\begin{aligned} \sum_{k=1}^9 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_9, v_9) \Delta A_9 \\ &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_9, v_9)] \cdot 1 \\ &= [f(1, 0) + f(2, 0) + f(3, 0) + f(1, 1) + f(2, 1) \\ &\quad + f(3, 1) + f(1, 2) + f(2, 2) + f(3, 2)] \cdot 1 \\ &= (3 + 6 + 9 + 2 + 4 + 6 + 1 + 2 + 3) \cdot 1 = \boxed{36}. \end{aligned}$$

- (b) Choose (u_k, v_k) , $k = 1, 2, \dots, 9$, as the upper left corner of the k th subsquare: $(u_1, v_1) = (0, 1)$, $(u_2, v_2) = (1, 1)$, $(u_3, v_3) = (2, 1)$, $(u_4, v_4) = (0, 2)$, $(u_5, v_5) = (1, 2)$, $(u_6, v_6) = (2, 2)$, $(u_7, v_7) = (0, 3)$, $(u_8, v_8) = (1, 3)$, and $(u_9, v_9) = (2, 3)$. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^9 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_9, v_9) \Delta A_9 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_9, v_9)] \cdot 1 \\
 &= [f(0, 1) + f(1, 1) + f(2, 1) + f(0, 2) + f(1, 2) \\
 &\quad + f(2, 2) + f(0, 3) + f(1, 3) + f(2, 3)] \cdot 1 \\
 &= (0 + 2 + 4 + 0 + 1 + 2 + 0 + 0 + 0) \cdot 1 = \boxed{9}.
 \end{aligned}$$

6. Let $f(x, y) = 3xy^2$, and let R be the closed rectangular region defined by $0 \leq x \leq 6$, $0 \leq y \leq 4$. Partition R into six congruent subsquares with sides $\Delta x_i = 2$, $i = 1, 2, 3$, and $\Delta y_j = 2$, $j = 1, 2$, each with area $\Delta A_k = 4$.

- (a) Choose (u_k, v_k) , $k = 1, 2, \dots, 6$, as the lower left corner of the k th subsquare: $(u_1, v_1) = (0, 0)$, $(u_2, v_2) = (2, 0)$, $(u_3, v_3) = (4, 0)$, $(u_4, v_4) = (0, 2)$, $(u_5, v_5) = (2, 2)$, and $(u_6, v_6) = (4, 2)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^6 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_6, v_6) \Delta A_6 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_6, v_6)] \cdot 4 \\
 &= [f(0, 0) + f(2, 0) + f(4, 0) + f(0, 2) + f(2, 2) + f(4, 2)] \cdot 4 \\
 &= (0 + 0 + 0 + 0 + 24 + 48) \cdot 4 = \boxed{288}.
 \end{aligned}$$

- (b) Choose (u_k, v_k) , $k = 1, 2, \dots, 6$, as the lower right corner of the k th subsquare: $(u_1, v_1) = (2, 0)$, $(u_2, v_2) = (4, 0)$, $(u_3, v_3) = (6, 0)$, $(u_4, v_4) = (2, 2)$, $(u_5, v_5) = (4, 2)$, and $(u_6, v_6) = (6, 2)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^6 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_6, v_6) \Delta A_6 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_6, v_6)] \cdot 4 \\
 &= [f(2, 0) + f(4, 0) + f(6, 0) + f(2, 2) + f(4, 2) + f(6, 2)] \cdot 4 \\
 &= (0 + 0 + 0 + 24 + 48 + 72) \cdot 4 = \boxed{576}.
 \end{aligned}$$

7. Let $f(x, y) = x^2 + y$, and let R be the closed rectangular region defined by $1 \leq x \leq 5$, $2 \leq y \leq 4$. Partition R into four congruent subrectangles with sides $\Delta x_i = 2$, $i = 1, 2$, and $\Delta y_j = 1$, $j = 1, 2$, each with area $\Delta A_k = 2$.

- (a) Choose (u_k, v_k) , $k = 1, 2, 3, 4$, as the lower left corner of the k th subrectangle: $(u_1, v_1) = (1, 2)$, $(u_2, v_2) = (3, 2)$, $(u_3, v_3) = (1, 3)$, and $(u_4, v_4) = (3, 3)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^4 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + f(u_3, v_3) \Delta A_3 + f(u_4, v_4) \Delta A_4 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + f(u_3, v_3) + f(u_4, v_4)] \cdot 2 \\
 &= [f(1, 2) + f(3, 2) + f(1, 3) + f(3, 3)] \cdot 2 \\
 &= (3 + 11 + 4 + 12) \cdot 2 = \boxed{60}.
 \end{aligned}$$

- (b) Choose (u_k, v_k) , $k = 1, 2, 3, 4$, as the upper right corner of the k th subrectangle: $(u_1, v_1) = (3, 3)$, $(u_2, v_2) = (5, 3)$, $(u_3, v_3) = (3, 4)$, and $(u_4, v_4) = (5, 4)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^4 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + f(u_3, v_3) \Delta A_3 + f(u_4, v_4) \Delta A_4 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + f(u_3, v_3) + f(u_4, v_4)] \cdot 2 \\
 &= [f(3, 3) + f(5, 3) + f(3, 4) + f(5, 4)] \cdot 2 \\
 &= (12 + 28 + 13 + 29) \cdot 2 = \boxed{164}.
 \end{aligned}$$

8. Let $f(x, y) = x(1 - y)$, and let R be the closed rectangular region defined by $0 \leq x \leq 3$, $0 \leq y \leq 4$. Partition R into six congruent subrectangles with sides $\Delta x_i = 1$, $i = 1, 2, 3$, and $\Delta y_j = 2$, $j = 1, 2$, each with area $\Delta A_k = 2$.

- (a) Choose (u_k, v_k) , $k = 1, 2, \dots, 6$, as the lower left corner of the k th subrectangle: $(u_1, v_1) = (0, 0)$, $(u_2, v_2) = (1, 0)$, $(u_3, v_3) = (2, 0)$, $(u_4, v_4) = (0, 2)$, $(u_5, v_5) = (1, 2)$, and $(u_6, v_6) = (2, 2)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^6 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_6, v_6) \Delta A_6 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_6, v_6)] \cdot 2 \\
 &= [f(0, 0) + f(1, 0) + f(2, 0) + f(0, 2) + f(1, 2) + f(2, 2)] \cdot 2 \\
 &= (0 + 1 + 2 + 0 - 1 - 2) \cdot 2 = \boxed{0}.
 \end{aligned}$$

- (b) Choose (u_k, v_k) , $k = 1, 2, \dots, 6$, as the upper left corner of the k th subrectangle: $(u_1, v_1) = (0, 2)$, $(u_2, v_2) = (1, 2)$, $(u_3, v_3) = (2, 2)$, $(u_4, v_4) = (0, 4)$, $(u_5, v_5) = (1, 4)$, and $(u_6, v_6) = (2, 4)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^6 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_6, v_6) \Delta A_6 \\
 &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_6, v_6)] \cdot 2 \\
 &= [f(0, 2) + f(1, 2) + f(2, 2) + f(0, 4) + f(1, 4) + f(2, 4)] \cdot 2 \\
 &= (0 - 1 - 2 + 0 - 3 - 6) \cdot 2 = \boxed{-24}.
 \end{aligned}$$

9. Let $f(x, y) = x^2y$, and let R be the closed rectangular region defined by $1 \leq x \leq 5$, $0 \leq y \leq 4$, as given in Example 1. Partition R into four congruent subrectangles with sides $\Delta x_i = 2$, $i = 1, 2$, and $\Delta y_j = 2$, $j = 1, 2$, each with area $\Delta A_k = 4$. Choose (u_k, v_k) , $k = 1, 2, 3, 4$, as the center of the k th subsquare: $(u_1, v_1) = (2, 1)$, $(u_2, v_2) = (4, 1)$, $(u_3, v_3) = (2, 3)$, and $(u_4, v_4) = (4, 3)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned} \sum_{k=1}^4 f(u_k, v_k) \Delta A_k &= f(2, 1) \cdot 4 + f(4, 1) \cdot 4 + f(2, 3) \cdot 4 + f(4, 3) \cdot 4 \\ &= [f(2, 1) + f(4, 1) + f(2, 3) + f(4, 3)] \cdot 4 \\ &= (4 + 16 + 12 + 48) \cdot 4 = \boxed{320}. \end{aligned}$$

10. Let $f(x, y) = x^2y$, and let R be the closed rectangular region defined by $1 \leq x \leq 5$, $0 \leq y \leq 4$, as given in Example 1. Partition R into eight congruent subrectangles with sides $\Delta x_i = 1$, $i = 1, 2, 3, 4$, and $\Delta y_j = 2$, $j = 1, 2$, each with area $\Delta A_k = 2$. Choose (u_k, v_k) , $k = 1, 2, \dots, 8$, as the center of the k th subrectangle: $(u_1, v_1) = \left(\frac{3}{2}, 1\right)$, $(u_2, v_2) = \left(\frac{5}{2}, 1\right)$, $(u_3, v_3) = \left(\frac{7}{2}, 1\right)$, $(u_4, v_4) = \left(\frac{9}{2}, 1\right)$, $(u_5, v_5) = \left(\frac{3}{2}, 3\right)$, $(u_6, v_6) = \left(\frac{5}{2}, 3\right)$, $(u_7, v_7) = \left(\frac{7}{2}, 3\right)$, and $(u_8, v_8) = \left(\frac{9}{2}, 3\right)$. See the figure below. Then the corresponding Riemann sum is:

$$\begin{aligned} \sum_{k=1}^8 f(u_k, v_k) \Delta A_k &= f(u_1, v_1) \Delta A_1 + f(u_2, v_2) \Delta A_2 + \cdots + f(u_8, v_8) \Delta A_8 \\ &= [f(u_1, v_1) + f(u_2, v_2) + \cdots + f(u_8, v_8)] \cdot 2 \\ &= \left[f\left(\frac{3}{2}, 1\right) + f\left(\frac{5}{2}, 1\right) + f\left(\frac{7}{2}, 1\right) + f\left(\frac{9}{2}, 1\right) \right. \\ &\quad \left. + f\left(\frac{3}{2}, 3\right) + f\left(\frac{5}{2}, 3\right) + f\left(\frac{7}{2}, 3\right) + f\left(\frac{9}{2}, 3\right) \right] \cdot 2 \\ &= \left(\frac{9}{4} + \frac{25}{4} + \frac{49}{4} + \frac{81}{4} + \frac{27}{4} + \frac{75}{4} + \frac{147}{4} + \frac{243}{4} \right) \cdot 2 = \boxed{328}. \end{aligned}$$

11. We integrate partially with respect to y , treating x as a constant:

$$\int_1^e \frac{x}{y} dy = x \int_1^e \frac{1}{y} dy = x[\ln |y|]_1^e = x(\ln e - \ln 1) = x(1 - 0) = \boxed{x}.$$

12. We integrate partially with respect to x , treating y as a constant:

$$\int_0^2 \frac{x}{y} dx = \frac{1}{y} \int_0^2 x dx = \frac{1}{y} \left[\frac{x^2}{2} \right]_0^2 = \frac{1}{y}(2 - 0) = \boxed{\frac{2}{y}}.$$

13. We integrate partially with respect to x , treating y as a constant:

$$\int_0^{\pi/2} x \sin y dx = \sin y \int_0^{\pi/2} x dx = \sin y \left[\frac{x^2}{2} \right]_0^{\pi/2} = \sin y \left(\frac{\pi^2}{8} - 0 \right) = \boxed{\frac{\pi^2}{8} \sin y}.$$

14. We integrate partially with respect to y , treating x as a constant:

$$\int_0^{\pi/2} x \sin y dy = x \int_0^{\pi/2} \sin y dy = x[-\cos y]_0^{\pi/2} = x \left(-\cos \frac{\pi}{2} + \cos 0 \right) = x(0 + 1) = \boxed{x}.$$

15. We integrate partially with respect to x , treating y as a constant:

$$\int_0^1 e^x dx = [e^x]_0^1 = e^1 - e^0 = \boxed{e - 1}.$$

16. We integrate partially with respect to y , treating x as a constant:

$$\int_0^1 e^x dy = e^x \int_0^1 1 dy = e^x [y]_0^1 = e^x(1 - 0) = \boxed{e^x}.$$

17. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\int_0^1 \left[\int_0^2 x^2 y dy \right] dx = \int_0^1 x^2 \left[\frac{y^2}{2} \right]_0^2 dx = \int_0^1 x^2(2 - 0) dx = \int_0^1 2x^2 dx = \left[\frac{2x^3}{3} \right]_0^1 = \frac{2}{3} - 0 = \boxed{\frac{2}{3}}.$$

18. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_0^2 \left[\int_0^4 x^2 y dx \right] dy = \int_0^2 y \left[\frac{x^3}{3} \right]_0^4 dy = \int_0^2 y \left(\frac{64}{3} - 0 \right) dy = \int_0^2 \frac{64}{3} y dy = \left[\frac{32y^2}{3} \right]_0^2 = \frac{128}{3} - 0 = \boxed{\frac{128}{3}}.$$

19. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\int_0^3 \left[\int_0^2 3xy \, dy \right] dx = \int_0^3 3x \left[\frac{y^2}{2} \right]_0^2 dx = \int_0^3 3x(2-0) \, dx = \int_0^3 6x \, dx = [3x^2]_0^3 = 27 - 0 = \boxed{27}.$$

20. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_0^2 \left[\int_0^1 3xy \, dx \right] dy = \int_0^2 3y \left[\frac{x^2}{2} \right]_0^1 dy = \int_0^2 3y \left(\frac{1}{2} - 0 \right) dy = \int_0^2 \frac{3}{2}y \, dy = \left[\frac{3y^2}{4} \right]_0^2 = 3 - 0 = \boxed{3}.$$

21. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_{-1}^1 \left[\int_0^1 3x^2y^2 \, dx \right] dy = \int_{-1}^1 y^2 [x^3]_0^1 dy = \int_{-1}^1 y^2(1-0) \, dy = \int_{-1}^1 y^2 \, dy = \left[\frac{y^3}{3} \right]_{-1}^1 = \frac{1}{3} - \left(-\frac{1}{3} \right) = \boxed{\frac{2}{3}}.$$

22. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\int_0^1 \left[\int_0^2 3x^2y^2 \, dy \right] dx = \int_0^1 x^2 [y^3]_0^2 dx = \int_0^1 x^2(8-0) \, dx = \int_0^1 8x^2 \, dx = \left[\frac{8}{3}x^3 \right]_0^1 = \frac{8}{3} - 0 = \boxed{\frac{8}{3}}.$$

23. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_0^2 \left[\int_{-1}^1 2xy^2 \, dx \right] dy = \int_0^2 y^2 [x^2]_{-1}^1 dy = \int_0^2 y^2(1-1) \, dy = \int_0^2 0 \, dy = \boxed{0}.$$

24. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\int_{-1}^1 \left[\int_1^2 2xy^2 \, dy \right] dx = \int_{-1}^1 2x \left[\frac{y^3}{3} \right]_1^2 dx = \int_{-1}^1 2x \left(\frac{8}{3} - \frac{1}{3} \right) dx = \int_{-1}^1 \frac{14}{3}x \, dx = \left[\frac{7}{3}x^2 \right]_{-1}^1 = \frac{7}{3} - \frac{7}{3} = \boxed{0}.$$

25. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\begin{aligned} \int_0^{\pi/4} \left[\int_0^2 x \cos y \, dx \right] dy &= \int_0^{\pi/4} \cos y \left[\frac{x^2}{2} \right]_0^2 dy = \int_0^{\pi/4} \cos y \cdot (2-0) \, dy \\ &= \int_0^{\pi/4} 2 \cos y \, dy = [2 \sin y]_0^{\pi/4} = 2 \sin \frac{\pi}{4} - 2 \sin 0 = 2 \cdot \frac{\sqrt{2}}{2} - 0 = \boxed{\sqrt{2}}. \end{aligned}$$

26. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\begin{aligned} \int_0^2 \left[\int_0^{\pi/3} x \cos y \, dy \right] dx &= \int_0^2 x [\sin y]_0^{\pi/3} dx = \int_0^2 x \left(\sin \frac{\pi}{3} - \sin 0 \right) dx \\ &= \int_0^2 x \left(\frac{\sqrt{3}}{2} - 0 \right) dx = \int_0^2 \frac{\sqrt{3}}{2}x \, dx = \left[\frac{\sqrt{3}}{4}x^2 \right]_0^2 = \sqrt{3} - 0 = \boxed{\sqrt{3}}. \end{aligned}$$

27. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\begin{aligned}\int_0^3 \left[\int_0^{\pi/3} (4x-3)^2 \sin y \, dy \right] dx &= \int_0^3 (4x-3)^2 [-\cos y]_0^{\pi/3} dx = \int_0^3 (4x-3)^2 \left(-\cos \frac{\pi}{3} + \cos 0 \right) dx \\ &= \int_0^3 (4x-3)^2 \left(-\frac{1}{2} + 1 \right) dx = \int_0^3 \frac{1}{2} (4x-3)^2 dx.\end{aligned}$$

In this integral we can make a substitution $u = 4x - 3$; then $du = 4dx$, so $dx = \frac{du}{4}$. We also change the limits of integration: if $x = 0$, then $u = 4 \cdot 0 - 3 = -3$; if $x = 3$, then $u = 4 \cdot 3 - 3 = 9$. So

$$\begin{aligned}\int_0^3 \frac{1}{2} (4x-3)^2 dx &= \int_{-3}^9 \frac{1}{2} u^2 \frac{du}{4} = \frac{1}{8} \int_{-3}^9 u^2 du = \frac{1}{8} \left[\frac{u^3}{3} \right]_{-3}^9 \\ &= \frac{1}{24} (9^3 - (-3)^3) = \frac{1}{24} (729 + 27) = \frac{756}{24} = \boxed{\frac{63}{2}}.\end{aligned}$$

28. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\begin{aligned}\int_0^{\pi/3} \left[\int_0^3 (4x-3) \sin y \, dx \right] dy &= \int_0^{\pi/3} \sin y \cdot [2x^2 - 3x]_0^3 dy = \int_0^{\pi/3} \sin y \cdot [(2 \cdot 3^2 - 3 \cdot 3) - 0] dy \\ &= \int_0^{\pi/3} 9 \sin y \, dy = 9 [-\cos y]_0^{\pi/3} = 9 \left(-\cos \frac{\pi}{3} + \cos 0 \right) \\ &= 9 \left(-\frac{1}{2} + 1 \right) = 9 \cdot \frac{1}{2} = \boxed{\frac{9}{2}}.\end{aligned}$$

29. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\begin{aligned}\int_0^1 \left[\int_0^{\pi/2} e^x \cos y \, dy \right] dx &= \int_0^1 e^x [\sin y]_0^{\pi/2} dx = \int_0^1 e^x \left(\sin \frac{\pi}{2} - \sin 0 \right) dx = \int_0^1 e^x (1 - 0) dx \\ &= \int_0^1 e^x dx = [e^x]_0^1 = e^1 - e^0 = \boxed{e - 1}.\end{aligned}$$

30. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\begin{aligned}\int_0^{\pi/4} \left[\int_0^1 e^x \cos y \, dx \right] dy &= \int_0^{\pi/4} \cos y \cdot [e^x]_0^1 dy = \int_0^{\pi/4} \cos y \cdot (e^1 - e^0) dy \\ &= \int_0^{\pi/4} (e - 1) \cos y \, dy = (e - 1) [\sin y]_0^{\pi/4} = (e - 1) \left(\sin \frac{\pi}{4} - \sin 0 \right) \\ &= (e - 1) \left(\frac{\sqrt{2}}{2} - 0 \right) = \boxed{\frac{(e - 1)\sqrt{2}}{2}}.\end{aligned}$$

31. We begin by using partial integration with respect to y to find the integral within the brackets. Then

we integrate the result with respect to x .

$$\begin{aligned}\int_0^2 \left[\int_{-\pi/2}^{\pi/2} \frac{\sin y}{2x+1} dy \right] dx &= \int_0^2 \frac{1}{2x+1} \left[\int_{-\pi/2}^{\pi/2} \sin y dy \right] dx = \int_0^2 \frac{1}{2x+1} [-\cos y]_{-\pi/2}^{\pi/2} dx \\ &= \int_0^2 \frac{1}{2x+1} \left[-\cos \frac{\pi}{2} + \cos \left(-\frac{\pi}{2} \right) \right] dx = \int_0^2 \frac{1}{2x+1} (-0+0) dx \\ &= \int_0^2 0 dx = \boxed{0}.\end{aligned}$$

32. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_0^{\pi/2} \left[\int_0^2 \frac{\sin y}{2x+1} dx \right] dy = \int_0^{\pi/2} \sin y \left[\int_0^2 \frac{1}{2x+1} dx \right] dy.$$

To find the integral in the brackets, we make a substitution $u = 2x + 1$; then $du = 2dx$, so $dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 2 \cdot 0 + 1 = 1$; if $x = 2$, then $u = 2 \cdot 2 + 1 = 5$. So

$$\int_0^2 \frac{1}{2x+1} dx = \int_1^5 \frac{1}{u} \frac{du}{2} = \frac{1}{2} \int_1^5 \frac{du}{u} = \frac{1}{2} [\ln |u|]_1^5 = \frac{1}{2} (\ln 5 - \ln 1) = \frac{\ln 5}{2}.$$

Going back to the given iterated integral, we find:

$$\begin{aligned}\int_0^{\pi/2} \sin y \left[\int_0^2 \frac{1}{2x+1} dx \right] dy &= \int_0^{\pi/2} \sin y \frac{\ln 5}{2} dy = \frac{\ln 5}{2} [-\cos y]_0^{\pi/2} \\ &= \frac{\ln 5}{2} \left(-\cos \frac{\pi}{2} + \cos 0 \right) = \frac{\ln 5}{2} (-0 + 1) = \boxed{\frac{\ln 5}{2}}.\end{aligned}$$

33. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_0^{\pi/2} \left[\int_0^2 x e^x \sin y dx \right] dy = \int_0^{\pi/2} \sin y \left[\int_0^2 x e^x dx \right] dy.$$

To find the integral in the brackets, we use the method of integration by parts. If we choose $u = x$ and $dv = e^x dx$, then $du = dx$ and $v = \int e^x dx = e^x$. So

$$\int_0^2 x e^x dx = [x e^x]_0^2 - \int_0^2 e^x dx = (2e^2 - 0e^0) - [e^x]_0^2 = 2e^2 - (e^2 - e^0) = 2e^2 - e^2 + 1 = e^2 + 1.$$

Going back to the given iterated integral, we find:

$$\begin{aligned}\int_0^{\pi/2} \sin y \left[\int_0^2 x e^x dx \right] dy &= \int_0^{\pi/2} \sin y \cdot (e^2 + 1) dy = (e^2 + 1) [-\cos y]_0^{\pi/2} \\ &= (e^2 + 1) \left(-\cos \frac{\pi}{2} + \cos 0 \right) = (e^2 + 1) (-0 + 1) = \boxed{e^2 + 1}.\end{aligned}$$

34. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\begin{aligned}\int_0^1 \left[\int_0^{\pi/2} x e^x \sin y dy \right] dx &= \int_0^1 x e^x \left[\int_0^{\pi/2} \sin y dy \right] dx = \int_0^1 x e^x [-\cos y]_0^{\pi/2} dx \\ &= \int_0^1 x e^x \left(-\cos \frac{\pi}{2} + \cos 0 \right) dx = \int_0^1 x e^x (-0 + 1) dx = \int_0^1 x e^x dx.\end{aligned}$$

To find this integral, we use the method of integration by parts. If we choose $u = x$ and $dv = e^x dx$, then $du = dx$ and $v = \int e^x dx = e^x$. So

$$\int_0^1 x e^x dx = [x e^x]_0^1 - \int_0^1 e^x dx = (1e^1 - 0e^0) - [e^x]_0^1 = e - (e^1 - e^0) = e - e + 1 = \boxed{1}.$$

35. We begin by using partial integration with respect to x to find the integral within the brackets. Then we integrate the result with respect to y .

$$\int_1^2 \left[\int_0^{\pi/2} \frac{x \cos x}{y} dx \right] dy = \int_1^2 \frac{1}{y} \left[\int_0^{\pi/2} x \cos x dx \right] dy.$$

To find the integral in the brackets, we use the method of integration by parts. If we choose $u = x$ and $dv = \cos x dx$, then $du = dx$ and $v = \int \cos x dx = \sin x$. So

$$\begin{aligned} \int_0^{\pi/2} x \cos x dx &= [x \sin x]_0^{\pi/2} - \int_0^{\pi/2} \sin x dx \\ &= \left(\frac{\pi}{2} \sin \frac{\pi}{2} - 0 \sin 0 \right) + [\cos x]_0^{\pi/2} = \frac{\pi}{2} + \left(\cos \frac{\pi}{2} - \cos 0 \right) = \frac{\pi}{2} - 1. \end{aligned}$$

Going back to the given iterated integral, we find:

$$\begin{aligned} \int_1^2 \frac{1}{y} \left[\int_0^{\pi/2} x \cos x dx \right] dy &= \int_1^2 \frac{1}{y} \left(\frac{\pi}{2} - 1 \right) dy = \left(\frac{\pi}{2} - 1 \right) [\ln |y|]_1^2 = \left(\frac{\pi}{2} - 1 \right) (\ln 2 - \ln 1) \\ &= \left(\frac{\pi}{2} - 1 \right) (\ln 2 - 0) = \left(\frac{\pi}{2} - 1 \right) \ln 2 = \boxed{\frac{(\pi - 2) \ln 2}{2}}. \end{aligned}$$

36. We begin by using partial integration with respect to y to find the integral within the brackets. Then we integrate the result with respect to x .

$$\begin{aligned} \int_0^{\pi/3} \left[\int_1^2 \frac{x \cos x}{y} dy \right] dx &= \int_0^{\pi/3} x \cos x \left[\int_1^2 \frac{1}{y} dy \right] dx = \int_0^{\pi/3} x \cos x \cdot [\ln |y|]_1^2 dx \\ &= \int_0^{\pi/3} x \cos x \cdot (\ln 2 - \ln 1) dx = \ln 2 \int_0^{\pi/3} x \cos x dx. \end{aligned}$$

To find this integral, we use the method of integration by parts. If we choose $u = x$ and $dv = \cos x dx$, then $du = dx$ and $v = \int \cos x dx = \sin x$. So

$$\begin{aligned} \ln 2 \int_0^{\pi/3} x \cos x dx &= \ln 2 \left[[x \sin x]_0^{\pi/3} - \int_0^{\pi/3} \sin x dx \right] \\ &= \ln 2 \left[\left(\frac{\pi}{3} \sin \frac{\pi}{3} - 0 \sin 0 \right) + [\cos x]_0^{\pi/3} \right] = \ln 2 \left[\frac{\pi}{3} \cdot \frac{\sqrt{3}}{2} + \left(\cos \frac{\pi}{3} - \cos 0 \right) \right] \\ &= \ln 2 \left[\frac{\pi\sqrt{3}}{6} + \left(\frac{1}{2} - 1 \right) \right] = \boxed{\ln 2 \left(\frac{\pi\sqrt{3}}{6} - \frac{1}{2} \right)}. \end{aligned}$$

37. Using Fubini's Theorem, the given double integral $\iint_R (2x + y^2) dA$, where R is the closed rectangular region defined by $0 \leq x \leq 2$, $0 \leq y \leq 3$, equals either of the iterated integrals:

$$\int_0^2 \left[\int_0^3 (2x + y^2) dy \right] dx \quad \text{or} \quad \int_0^3 \left[\int_0^2 (2x + y^2) dx \right] dy.$$

Using the latter iterated integral, we begin integrating partially with respect to x to find the integral within the brackets, and then we integrate the result with respect to y .

$$\begin{aligned}\iint_R (2x + y^2) dA &= \int_0^3 \left[\int_0^2 (2x + y^2) dx \right] dy = \int_0^3 [x^2 + xy^2]_0^2 dy = \int_0^3 [(4 + 2y^2) - 0] dy \\ &= \int_0^3 (4 + 2y^2) dy = \left[4y + \frac{2y^3}{3} \right]_0^3 = (12 + 18) - 0 = \boxed{30}.\end{aligned}$$

38. Using Fubini's Theorem, the given double integral $\iint_R (x^2 - 3y) dA$, where R is the closed rectangular region defined by $-1 \leq x \leq 2$, $0 \leq y \leq 1$, equals either of the iterated integrals:

$$\int_{-1}^2 \left[\int_0^1 (x^2 - 3y) dy \right] dx \quad \text{or} \quad \int_0^1 \left[\int_{-1}^2 (x^2 - 3y) dx \right] dy.$$

Using the former iterated integral, we begin by integrating partially with respect to y to find the integral within the brackets, and then we integrate the result with respect to x .

$$\begin{aligned}\iint_R (x^2 - 3y) dA &= \int_{-1}^2 \left[\int_0^1 (x^2 - 3y) dy \right] dx = \int_{-1}^2 \left[x^2 y - \frac{3y^2}{2} \right]_0^1 dx = \int_{-1}^2 \left[\left(x^2 - \frac{3}{2} \right) - 0 \right] dx \\ &= \int_{-1}^2 \left(x^2 - \frac{3}{2} \right) dx = \left[\frac{x^3}{3} - \frac{3x}{2} \right]_{-1}^2 = \left(\frac{8}{3} - 3 \right) - \left(\frac{-1}{3} - \frac{-3}{2} \right) = \boxed{-\frac{3}{2}}.\end{aligned}$$

39. Using Fubini's Theorem, the given double integral $\iint_R x(x^2 + 5) dA = \iint_R (x^3 + 5x) dA$, where R is the closed rectangular region defined by $0 \leq x \leq 2$, $-1 \leq y \leq 1$, equals either of the iterated integrals:

$$\int_0^2 \left[\int_{-1}^1 (x^3 + 5x) dy \right] dx \quad \text{or} \quad \int_{-1}^1 \left[\int_0^2 (x^3 + 5x) dx \right] dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x to find the integral within the brackets, and then we integrate the result with respect to y .

$$\begin{aligned}\iint_R x(x^2 + 5) dA &= \iint_R (x^3 + 5x) dA = \int_{-1}^1 \left[\int_0^2 (x^3 + 5x) dx \right] dy = \int_{-1}^1 \left[\frac{x^4}{4} + \frac{5x^2}{2} \right]_0^2 dy \\ &= \int_{-1}^1 [(4 + 10) - 0] dy = \int_{-1}^1 14 dy = [14y]_{-1}^1 = 14 - (-14) = \boxed{28}.\end{aligned}$$

40. Using Fubini's Theorem, the given double integral $\iint_R \sqrt{y}(3x^2 + x) dA$, where R is the closed rectangular region defined by $0 \leq x \leq 2$, $0 \leq y \leq 4$, equals either of the iterated integrals:

$$\int_0^2 \left[\int_0^4 \sqrt{y}(3x^2 + x) dy \right] dx \quad \text{or} \quad \int_0^4 \left[\int_0^2 \sqrt{y}(3x^2 + x) dx \right] dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x to find the integral within the brackets, and then we integrate the result with respect to y .

$$\begin{aligned}\iint_R \sqrt{y}(3x^2 + x) dA &= \int_0^4 \left[\int_0^2 \sqrt{y}(3x^2 + x) dx \right] dy = \int_0^4 \sqrt{y} \left[\int_0^2 (3x^2 + x) dx \right] dy \\ &= \int_0^4 \sqrt{y} \left[x^3 + \frac{x^2}{2} \right]_0^2 dy = \int_0^4 \sqrt{y} [(8 + 2) - 0] dy = \int_0^4 10y^{1/2} dy \\ &= \left[10 \cdot \frac{y^{3/2}}{3/2} \right]_0^4 = \left[\frac{20}{3} (\sqrt{y})^3 \right]_0^4 = \frac{20}{3} (\sqrt{4})^3 - \frac{20}{3} (\sqrt{0})^3 = \frac{160}{3} - 0 = \boxed{\frac{160}{3}}.\end{aligned}$$

41. Using Fubini's Theorem, the given double integral $\iint_R 2xe^y dA$, where R is the closed rectangular region defined by $-3 \leq x \leq 2$, $0 \leq y \leq 1$, equals either of the iterated integrals:

$$\int_{-3}^2 \left[\int_0^1 2xe^y dy \right] dx \quad \text{or} \quad \int_0^1 \left[\int_{-3}^2 2xe^y dx \right] dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x to find the integral within the brackets, and then we integrate the result with respect to y .

$$\begin{aligned} \iint_R 2xe^y dA &= \int_0^1 \left[\int_{-3}^2 2xe^y dx \right] dy = \int_0^1 e^y \left[\int_{-3}^2 2x dx \right] dy = \int_0^1 e^y [x^2]_{-3}^2 dy = \int_0^1 e^y (4 - 9) dy \\ &= \int_0^1 (-5)e^y dy = -5[e^y]_0^1 = -5(e^1 - e^0) = -5(e - 1) = \boxed{5(1 - e)}. \end{aligned}$$

42. Using Fubini's Theorem, the given double integral $\iint_R e^{2x+y} dA = \iint_R e^{2x} e^y dA$, where R is the closed rectangular region defined by $0 \leq x \leq 1$, $-1 \leq y \leq 1$, equals either of the iterated integrals:

$$\int_0^1 \left[\int_{-1}^1 e^{2x} e^y dy \right] dx \quad \text{or} \quad \int_{-1}^1 \left[\int_0^1 e^{2x} e^y dx \right] dy.$$

Using the former iterated integral, we begin by integrating partially with respect to y to find the integral within the brackets, and then we integrate the result with respect to x .

$$\begin{aligned} \iint_R e^{2x+y} dA &= \iint_R e^{2x} e^y dA = \int_0^1 \left[\int_{-1}^1 e^{2x} e^y dy \right] dx = \int_0^1 e^{2x} \left[\int_{-1}^1 e^y dy \right] dx \\ &= \int_0^1 e^{2x} [e^y]_{-1}^1 dx = \int_0^1 e^{2x} (e^1 - e^{-1}) dx = \left(e - \frac{1}{e} \right) \int_0^1 e^{2x} dx. \end{aligned}$$

To find the remaining integral $\int_0^1 e^{2x} dx$, we make a substitution $u = 2x$; then $du = 2dx$, so $dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 2 \cdot 0 = 0$; if $x = 1$, then $u = 2 \cdot 1 = 2$. So

$$\int_0^1 e^{2x} dx = \int_0^2 e^u \frac{du}{2} = \frac{1}{2} \int_0^2 e^u du = \frac{1}{2} [e^u]_0^2 = \frac{1}{2} (e^2 - e^0) = \frac{1}{2} (e^2 - 1).$$

Then the final answer is

$$\iint_R e^{2x+y} dA = \left(e - \frac{1}{e} \right) \cdot \frac{1}{2} (e^2 - 1) = \frac{e^2 - 1}{e} \cdot \frac{e^2 - 1}{2} = \frac{e^4 - 2e^2 + 1}{2e} = \boxed{\frac{e^3}{2} - e + \frac{1}{2e}}.$$

43. Using Fubini's Theorem, the given double integral $\iint_R x \sec^2 y dA$, where R is the closed rectangular region defined by $0 \leq x \leq 3$, $0 \leq y \leq \frac{\pi}{4}$, equals either of the iterated integrals:

$$\int_0^3 \left[\int_0^{\pi/4} x \sec^2 y dy \right] dx \quad \text{or} \quad \int_0^{\pi/4} \left[\int_0^3 x \sec^2 y dx \right] dy.$$

Using the former iterated integral, we begin by integrating partially with respect to y to find the integral within the brackets, and then we integrate the result with respect to x .

$$\begin{aligned} \int_0^3 \left[\int_0^{\pi/4} x \sec^2 y dy \right] dx &= \int_0^3 x \left[\int_0^{\pi/4} \sec^2 y dy \right] dx = \int_0^3 x [\tan y]_0^{\pi/4} dx \\ &= \int_0^3 x \left(\tan \frac{\pi}{4} - \tan 0 \right) dx = \int_0^3 x(1 - 0) dx = \int_0^3 x dx \\ &= \left[\frac{x^2}{2} \right]_0^3 = \frac{3^2}{2} - \frac{0^2}{2} = \frac{9}{2} - 0 = \boxed{\frac{9}{2}}. \end{aligned}$$

44. Using Fubini's Theorem, the given double integral $\iint_R y^2 \sec x \tan x \, dA$, where R is the closed rectangular region defined by $0 \leq x \leq \frac{\pi}{3}$, $-1 \leq y \leq 3$, equals either of the iterated integrals:

$$\int_0^{\pi/3} \left[\int_{-1}^3 y^2 \sec x \tan x \, dy \right] dx \quad \text{or} \quad \int_{-1}^3 \left[\int_0^{\pi/3} y^2 \sec x \tan x \, dx \right] dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x to find the integral within the brackets, and then we integrate the result with respect to y .

$$\begin{aligned} \int_{-1}^3 \left[\int_0^{\pi/3} y^2 \sec x \tan x \, dx \right] dy &= \int_{-1}^3 y^2 \left[\int_0^{\pi/3} \sec x \tan x \, dx \right] dy = \int_{-1}^3 y^2 [\sec x]_0^{\pi/3} dy \\ &= \int_{-1}^3 y^2 \left(\sec \frac{\pi}{3} - \sec 0 \right) dy = \int_{-1}^3 y^2 (2 - 1) dy = \int_{-1}^3 y^2 dy \\ &= \left[\frac{y^3}{3} \right]_{-1}^3 = \frac{3^3}{3} - \frac{(-1)^3}{3} = 9 + \frac{1}{3} = \boxed{\frac{28}{3}}. \end{aligned}$$

45. Using Fubini's Theorem, the given double integral $\iint_R \frac{x}{2y+3} \, dA$, where R is the closed rectangular region defined by $0 \leq x \leq 2$, $0 \leq y \leq 1$, equals either of the iterated integrals:

$$\int_0^2 \left[\int_0^1 \frac{x}{2y+3} \, dy \right] dx \quad \text{or} \quad \int_0^1 \left[\int_0^2 \frac{x}{2y+3} \, dx \right] dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x to find the integral within the brackets, and then we integrate the result with respect to y .

$$\begin{aligned} \int_0^1 \left[\int_0^2 \frac{x}{2y+3} \, dx \right] dy &= \int_0^1 \frac{1}{2y+3} \left[\int_0^2 x \, dx \right] dy \\ &= \int_0^1 \frac{1}{2y+3} \left[\frac{x^2}{2} \right]_0^2 dy = \int_0^1 \frac{1}{2y+3} (2 - 0) dy = \int_0^1 \frac{2}{2y+3} dy. \end{aligned}$$

To find the remaining integral, we make a substitution $u = 2y + 3$; then $du = 2dy$, so $dy = \frac{du}{2}$. We also change the limits of integration: if $y = 0$, then $u = 2 \cdot 0 + 3 = 3$; if $y = 1$, then $u = 2 \cdot 1 + 3 = 5$. So

$$\int_0^1 \frac{2}{2y+3} dy = \int_3^5 \frac{2}{u} \frac{du}{2} = \int_3^5 \frac{du}{u} = [\ln |u|]_3^5 = \ln 5 - \ln 3 = \boxed{\ln \frac{5}{3}}.$$

46. Using Fubini's Theorem, the given double integral $\iint_R \frac{y^2}{x-3} \, dA$, where R is the closed rectangular region defined by $4 \leq x \leq 5$, $0 \leq y \leq 3$, equals either of the iterated integrals:

$$\int_4^5 \left[\int_0^3 \frac{y^2}{x-3} \, dy \right] dx \quad \text{or} \quad \int_0^3 \left[\int_4^5 \frac{y^2}{x-3} \, dx \right] dy.$$

Using the former iterated integral, we begin by integrating partially with respect to y to find the integral within the brackets, and then we integrate the result with respect to x .

$$\begin{aligned} \int_4^5 \left[\int_0^3 \frac{y^2}{x-3} \, dy \right] dx &= \int_4^5 \frac{1}{x-3} \left[\int_0^3 y^2 \, dy \right] dx \\ &= \int_4^5 \frac{1}{x-3} \left[\frac{y^3}{3} \right]_0^3 dx = \int_4^5 \frac{1}{x-3} (9 - 0) dx = \int_4^5 \frac{9}{x-3} dx. \end{aligned}$$

To find the remaining integral, we make a substitution $u = x - 3$; then $du = dx$. We also change the limits of integration: if $x = 4$, then $u = 4 - 3 = 1$; if $x = 5$, then $u = 5 - 3 = 2$. So

$$\int_4^5 \frac{9}{x-3} dx = \int_1^2 \frac{9}{u} du = 9 \int_1^2 \frac{du}{u} = 9[\ln |u|]_1^2 = 9(\ln 2 - \ln 1) = 9(\ln 2 - 0) = \boxed{9 \ln 2}.$$

Applications and Extensions

47. Let R be the closed rectangular region defined by $0 \leq x \leq \frac{\pi}{2}$, $0 \leq y \leq 1$. Using Fubini's Theorem,

$$\iint_R x \sin(xy) dA = \int_0^{\pi/2} \left[\int_0^1 x \sin(xy) dy \right] dx.$$

To find the integral in the brackets $\int_0^1 x \sin(xy) dy$, we integrate partially with respect to y treating x as a constant. We make a substitution $u = xy$; then $du = x dy$, so $dy = \frac{du}{x}$. We also change the limits of integration: if $y = 0$, then $u = x \cdot 0 = 0$; if $y = 1$, then $u = x \cdot 1 = x$. So

$$\int_0^1 x \sin(xy) dy = \int_0^x x \sin u \frac{du}{x} = \int_0^x \sin u du = [-\cos u]_0^x = -\cos x + \cos 0 = -\cos x + 1.$$

Then going back to the iterated integral, we obtain:

$$\begin{aligned} \iint_R x \sin(xy) dA &= \int_0^{\pi/2} \left[\int_0^1 x \sin(xy) dy \right] dx = \int_0^{\pi/2} (-\cos x + 1) dx = [-\sin x + x]_0^{\pi/2} \\ &= \left(-\sin \frac{\pi}{2} + \frac{\pi}{2} \right) - (-\sin 0 + 0) = \frac{\pi}{2} - 1 = \boxed{\frac{\pi - 2}{2}}. \end{aligned}$$

48. Let R be the closed rectangular region defined by $0 \leq x \leq 1$, $\frac{\pi}{2} \leq y \leq 2\pi$. Using Fubini's Theorem,

$$\iint_R y \cos(xy) dA = \int_{\pi/2}^{2\pi} \left[\int_0^1 y \cos(xy) dx \right] dy.$$

To find the integral in the brackets $\int_0^1 y \cos(xy) dx$, we integrate partially with respect to x treating y as a constant. We make a substitution $u = xy$; then $du = y dx$, so $dx = \frac{du}{y}$. We also change the limits of integration: if $x = 0$, then $u = 0 \cdot y = 0$; if $x = 1$, then $u = 1 \cdot y = y$. So

$$\int_0^1 y \cos(xy) dx = \int_0^y y \cos u \frac{du}{y} = \int_0^y \cos u du = [\sin u]_0^y = \sin y - \sin 0 = \sin y - 0 = \sin y.$$

Then going back to the iterated integral, we obtain:

$$\begin{aligned} \iint_R y \cos(xy) dA &= \int_{\pi/2}^{2\pi} \left[\int_0^1 y \cos(xy) dx \right] dy = \int_{\pi/2}^{2\pi} \sin y dy \\ &= [-\cos y]_{\pi/2}^{2\pi} = -\cos 2\pi + \cos \frac{\pi}{2} = -1 + 0 = \boxed{-1}. \end{aligned}$$

49. Let R be the closed rectangular region defined by $0 \leq x \leq \frac{\pi}{2}$, $0 \leq y \leq 1$. Using Fubini's Theorem,

$$\iint_R x^3 \cos(x^2 y) dA = \int_0^{\pi/2} \left[\int_0^1 x^3 \cos(x^2 y) dy \right] dx.$$

To find the integral in the brackets $\int_0^1 x^3 \cos(x^2 y) dy$, we integrate partially with respect to y treating x as a constant. We make a substitution $u = x^2 y$; then $du = x^2 dy$, so $dy = \frac{du}{x^2}$. We also change the limits of integration: if $y = 0$, then $u = x^2 \cdot 0 = 0$; if $y = 1$, then $u = x^2 \cdot 1 = x^2$. So

$$\begin{aligned} \int_0^1 x^3 \cos(x^2 y) dy &= \int_0^{x^2} x^3 \cos u \frac{du}{x^2} = \int_0^{x^2} x \cos u du = x \int_0^{x^2} \cos u du \\ &= x [\sin u]_0^{x^2} = x [\sin(x^2) - \sin 0] = x [\sin(x^2) - 0] = x \sin(x^2). \end{aligned}$$

Then going back to the iterated integral:

$$\int_0^{\pi/2} \left[\int_0^1 x^3 \cos(x^2 y) dy \right] dx = \int_0^{\pi/2} x \sin(x^2) dx.$$

To find this integral we make a substitution $v = x^2$; then $dv = 2x dx$, so $x dx = \frac{dv}{2}$. We also change the limits of integration: if $x = 0$, then $v = 0^2 = 0$; if $x = \frac{\pi}{2}$, then $v = \left(\frac{\pi}{2}\right)^2 = \frac{\pi^2}{4}$. So

$$\begin{aligned} \int_0^{\pi/2} x \sin(x^2) dx &= \int_0^{\pi^2/4} \sin v \frac{dv}{2} = \frac{1}{2} \int_0^{\pi^2/4} \sin v dv = \frac{1}{2} [-\cos v]_0^{\pi^2/4} \\ &= \frac{1}{2} \left[-\cos \frac{\pi^2}{4} + \cos 0 \right] = \frac{1}{2} \left[-\cos \frac{\pi^2}{4} + 1 \right] = \boxed{\frac{1}{2} - \frac{1}{2} \cos \frac{\pi^2}{4}}. \end{aligned}$$

50. Let R be the closed rectangular region defined by $0 \leq x \leq \frac{\pi}{2}$, $0 \leq y \leq 1$. Using Fubini's Theorem,

$$\iint_R x^3 \sin(x^2 y) dA = \int_0^{\pi/2} \left[\int_0^1 x^3 \sin(x^2 y) dy \right] dx.$$

To find the integral in the brackets $\int_0^1 x^3 \sin(x^2 y) dy$, we integrate partially with respect to y treating x as a constant. We make a substitution $u = x^2 y$; then $du = x^2 dy$, so $dy = \frac{du}{x^2}$. We also change the limits of integration: if $y = 0$, then $u = x^2 \cdot 0 = 0$; if $y = 1$, then $u = x^2 \cdot 1 = x^2$. So

$$\begin{aligned} \int_0^1 x^3 \sin(x^2 y) dy &= \int_0^{x^2} x^3 \sin u \frac{du}{x^2} = \int_0^{x^2} x \sin u du = x \int_0^{x^2} \sin u du \\ &= x [-\cos u]_0^{x^2} = x [-\cos(x^2) + \cos 0] = x [-\cos(x^2) + 1] = x - x \cos(x^2). \end{aligned}$$

Then going back to the iterated integral:

$$\int_0^{\pi/2} \left[\int_0^1 x^3 \sin(x^2 y) dy \right] dx = \int_0^{\pi/2} [x - x \cos(x^2)] dx = \int_0^{\pi/2} x dx - \int_0^{\pi/2} x \cos(x^2) dx.$$

The first integral is

$$\int_0^{\pi/2} x dx = \left[\frac{x^2}{2} \right]_0^{\pi/2} = \left[\frac{(\pi/2)^2}{2} - \frac{0^2}{2} \right] = \frac{\pi^2}{8}.$$

To find the second integral we make a substitution $v = x^2$; then $dv = 2x dx$, so $x dx = \frac{dv}{2}$. We also change the limits of integration: if $x = 0$, then $v = 0^2 = 0$; if $x = \frac{\pi}{2}$, then $v = \left(\frac{\pi}{2}\right)^2 = \frac{\pi^2}{4}$. So

$$\begin{aligned} \int_0^{\pi/2} x \cos(x^2) dx &= \int_0^{\pi^2/4} \cos v \frac{dv}{2} = \frac{1}{2} \int_0^{\pi^2/4} \cos v dv = \frac{1}{2} [\sin v]_0^{\pi^2/4} \\ &= \frac{1}{2} \left[\sin \frac{\pi^2}{4} - \sin 0 \right] = \frac{1}{2} \left[\sin \frac{\pi^2}{4} - 0 \right] = \frac{1}{2} \sin \frac{\pi^2}{4}. \end{aligned}$$

So the final answer is

$$\iint_R x^3 \sin(x^2 y) dA = \int_0^{\pi/2} x dx - \int_0^{\pi/2} x \cos(x^2) dx = \boxed{\frac{\pi^2}{8} - \frac{1}{2} \sin \frac{\pi^2}{4}}.$$

51. Let R be the closed rectangular region defined by $0 \leq x \leq 2$, $0 \leq y \leq 3$. Using Fubini's Theorem,

$$\iint_R \frac{y^2}{(1+xy^2)^3} dA = \int_0^3 \left[\int_0^2 \frac{y^2}{(1+xy^2)^3} dx \right] dy.$$

To find the integral in the brackets, we integrate partially with respect to x treating y as a constant. We make a substitution $u = 1 + xy^2$; then $du = y^2 dx$, so $dx = \frac{du}{y^2}$. We also change the limits of integration: if $x = 0$, then $u = 1 + 0y^2 = 1$; if $x = 2$, then $u = 1 + 2y^2$. So

$$\begin{aligned} \int_0^2 \frac{y^2}{(1+xy^2)^3} dx &= \int_1^{1+2y^2} \frac{y^2}{u^3} \frac{du}{y^2} = \int_1^{1+2y^2} \frac{du}{u^3} = \int_1^{1+2y^2} u^{-3} du \\ &= \left[\frac{u^{-2}}{-2} \right]_1^{1+2y^2} = \left[-\frac{1}{2u^2} \right]_1^{1+2y^2} = -\frac{1}{2(1+2y^2)^2} + \frac{1}{2} = \frac{1}{2} - \frac{1}{8(\frac{1}{2} + y^2)^2}. \end{aligned}$$

Then going back to the iterated integral:

$$\int_0^3 \left[\int_0^2 \frac{y^2}{(1+xy^2)^3} dx \right] dy = \int_0^3 \left(\frac{1}{2} - \frac{1}{8(\frac{1}{2} + y^2)^2} \right) dy = \int_0^3 \frac{1}{2} dy - \frac{1}{8} \int_0^3 \frac{1}{(\frac{1}{2} + y^2)^2} dy.$$

The first integral is

$$\int_0^3 \frac{1}{2} dy = \frac{1}{2} [y]_0^3 = \frac{1}{2} \cdot 3 - \frac{1}{2} \cdot 0 = \frac{3}{2}.$$

To find the second integral, we will find an antiderivative using a substitution $y = \frac{1}{\sqrt{2}} \tan \theta$, $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$; then $dy = \frac{1}{\sqrt{2}} \sec^2 \theta d\theta$. Also,

$$\frac{1}{2} + y^2 = \frac{1}{2} + \frac{1}{2} \tan^2 \theta = \frac{1}{2} (1 + \tan^2 \theta) = \frac{1}{2} \sec^2 \theta,$$

and the integral becomes

$$\begin{aligned} \frac{1}{8} \int \frac{1}{(\frac{1}{2} + y^2)^2} dy &= \frac{1}{8} \int \frac{\frac{1}{\sqrt{2}} \sec^2 \theta d\theta}{(\frac{1}{2} \sec^2 \theta)^2} = \frac{1}{8} \int \frac{\frac{1}{\sqrt{2}} \sec^2 \theta d\theta}{\frac{1}{4} \sec^4 \theta} = \frac{1}{8} \int \frac{4}{\sqrt{2}} \frac{1}{\sec^2 \theta} d\theta \\ &= \frac{1}{2\sqrt{2}} \int \cos^2 \theta d\theta = \frac{1}{2\sqrt{2}} \int \frac{1}{2} (1 + \cos 2\theta) d\theta = \frac{1}{4\sqrt{2}} \int (1 + \cos 2\theta) d\theta \\ &= \frac{1}{4\sqrt{2}} \left(\theta + \frac{1}{2} \sin 2\theta \right) = \frac{1}{4\sqrt{2}} (\theta + \sin \theta \cos \theta). \end{aligned}$$

To express this antiderivative in terms of y , we first observe that since $y = \frac{1}{\sqrt{2}} \tan \theta$, then $\tan \theta = \sqrt{2}y$ and $\theta = \tan^{-1}(\sqrt{2}y)$; we also use trigonometric identities as follows:

$$\sin \theta \cos \theta = \frac{\sin \theta}{\cos \theta} \cdot \cos^2 \theta = \frac{\tan \theta}{\sec^2 \theta} = \frac{\tan \theta}{1 + \tan^2 \theta} = \frac{\sqrt{2}y}{1 + 2y^2}.$$

So,

$$\frac{1}{4\sqrt{2}} (\theta + \sin \theta \cos \theta) = \frac{1}{4\sqrt{2}} \left(\tan^{-1}(\sqrt{2}y) + \frac{\sqrt{2}y}{1 + 2y^2} \right) = \frac{1}{4\sqrt{2}} \tan^{-1}(\sqrt{2}y) + \frac{y}{4(1 + 2y^2)}$$

is an antiderivative, and

$$\begin{aligned}
 \frac{1}{8} \int_0^3 \frac{1}{(\frac{1}{2} + y^2)^2} dy &= \left[\frac{1}{4\sqrt{2}} \tan^{-1}(\sqrt{2}y) + \frac{y}{4(1+2y^2)} \right]_0^3 \\
 &= \left(\frac{1}{4\sqrt{2}} \tan^{-1}(\sqrt{2} \cdot 3) + \frac{3}{4(1+2 \cdot 3^2)} \right) - \left(\frac{1}{4\sqrt{2}} \tan^{-1}(\sqrt{2} \cdot 0) + \frac{0}{4(1+2 \cdot 0^2)} \right) \\
 &= \left(\frac{1}{4\sqrt{2}} \tan^{-1}(3\sqrt{2}) + \frac{3}{76} \right) - \left(\frac{1}{4\sqrt{2}} \tan^{-1}(0) + 0 \right) \\
 &= \left(\frac{1}{4\sqrt{2}} \tan^{-1}(3\sqrt{2}) + \frac{3}{76} \right) - (0 + 0) = \frac{1}{4\sqrt{2}} \tan^{-1}(3\sqrt{2}) + \frac{3}{76}.
 \end{aligned}$$

So the final answer is

$$\frac{3}{2} - \left(\frac{1}{4\sqrt{2}} \tan^{-1}(3\sqrt{2}) + \frac{3}{76} \right) = \frac{3}{2} - \frac{3}{76} - \frac{1}{4\sqrt{2}} \tan^{-1}(3\sqrt{2}) = \boxed{\frac{111}{76} - \frac{\sqrt{2}}{8} \tan^{-1}(3\sqrt{2})}.$$

52. Let R be the closed rectangular region defined by $0 \leq x \leq 1$, $0 \leq y \leq 1$. Using Fubini's Theorem,

$$\begin{aligned}
 \iint_R (x^3 + x)(x^2y + y) dA &= \int_0^1 \left[\int_0^1 (x^3 + x)(x^2y + y) dy \right] dx = \int_0^1 \left[\int_0^1 x(x^2 + 1)y(x^2 + 1) dy \right] dx \\
 &= \int_0^1 \left[\int_0^1 xy(x^2 + 1)^2 dy \right] dx = \int_0^1 x(x^2 + 1)^2 \left[\int_0^1 y dy \right] dx \\
 &= \int_0^1 x(x^2 + 1)^2 \left[\frac{y^2}{2} \right]_0^1 dx = \int_0^1 x(x^2 + 1)^2 \left(\frac{1}{2} - 0 \right) dx \\
 &= \frac{1}{2} \int_0^1 x(x^2 + 1)^2 dx.
 \end{aligned}$$

To find the remaining integral, we make a substitution $u = x^2 + 1$; then $du = 2x dx$, so $x dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 + 1 = 1$; if $x = 1$, then $u = 1^2 + 1 = 2$. So

$$\frac{1}{2} \int_0^1 x(x^2 + 1)^2 dx = \frac{1}{2} \int_1^2 u^2 \frac{du}{2} = \frac{1}{4} \int_1^2 u^2 du = \frac{1}{4} \left[\frac{u^3}{3} \right]_1^2 = \frac{1}{4} \left(\frac{8}{3} - \frac{1}{3} \right) = \frac{1}{4} \cdot \frac{7}{3} = \boxed{\frac{7}{12}}.$$

53. (a) Let R be the closed rectangular region defined by $0 \leq x \leq 1$, $0 \leq y \leq 2$. Using Fubini's Theorem,

$$\iint_R y^5 e^{xy^3} dA = \int_0^2 \left[\int_0^1 y^5 e^{xy^3} dx \right] dy = \int_0^2 y^5 \left[\int_0^1 e^{xy^3} dx \right] dy.$$

To find the integral in the brackets, we integrate partially with respect to x treating y as a constant. We make a substitution $u = xy^3$; then $du = y^3 dx$, so $dx = \frac{du}{y^3}$. We also change the limits of integration: if $x = 0$, then $u = 0 \cdot y^3 = 0$; if $x = 1$, then $u = 1 \cdot y^3 = y^3$. So

$$\int_0^1 e^{xy^3} dx = \int_0^{y^3} e^u \frac{du}{y^3} = \frac{1}{y^3} \int_0^{y^3} e^u du = \frac{1}{y^3} [e^u]_0^{y^3} = \frac{1}{y^3} (e^{y^3} - e^0) = \frac{1}{y^3} (e^{y^3} - 1).$$

Going back to the iterated integral,

$$\int_0^2 y^5 \left[\int_0^1 e^{xy^3} dx \right] dy = \int_0^2 y^5 \cdot \frac{1}{y^3} (e^{y^3} - 1) dy = \int_0^2 y^2 (e^{y^3} - 1) dy.$$

Here we make a substitution $v = y^3$; then $dv = 3y^2 dy$, so $y^2 dy = \frac{dv}{3}$. We also change the limits of integration: if $y = 0$, then $v = 0^3 = 0$; if $y = 2$, then $v = 2^3 = 8$. So

$$\begin{aligned} \int_0^2 y^2 (e^{y^3} - 1) dy &= \int_0^8 (e^v - 1) \frac{dv}{3} = \frac{1}{3} \int_0^8 (e^v - 1) dv = \frac{1}{3} [e^v - v]_0^8 \\ &= \frac{1}{3} [(e^8 - 8) - (e^0 - 0)] = \frac{1}{3} (e^8 - 8 - 1 + 0) = \boxed{\frac{1}{3} (e^8 - 9)}. \end{aligned}$$

- (b) Using Fubini's Theorem, we can change the order of integration and also represent the given double integral as

$$\iint_R y^5 e^{xy^3} dA = \int_0^1 \left[\int_0^2 y^5 e^{xy^3} dy \right] dx.$$

Entering this iterated integral into the computer algebra system *Mathematica*, we find that

$$\int_0^1 \left[\int_0^2 y^5 e^{xy^3} dy \right] dx = \boxed{\frac{1}{3} (-9 + e^8)},$$

which agrees with the answer found in part (a).

54. (a) Let R be the closed rectangular region defined by $0 \leq x \leq 2$, $0 \leq y \leq 1$. Using Fubini's Theorem,

$$\iint_R x^5 y e^{x^3 y^2} dA = \int_0^2 \left[\int_0^1 x^5 y e^{x^3 y^2} dy \right] dx = \int_0^2 x^5 \left[\int_0^1 y e^{x^3 y^2} dy \right] dx.$$

To find the integral in the brackets, we integrate partially with respect to y treating x as a constant. We make a substitution $u = x^3 y^2$; then $du = 2x^3 y dy$, so $y dy = \frac{du}{2x^3}$. We also change the limits of integration: if $y = 0$, then $u = x^3 \cdot 0^2 = 0$; if $y = 1$, then $u = x^3 \cdot 1^2 = x^3$. So

$$\int_0^1 y e^{x^3 y^2} dy = \int_0^{x^3} e^u \frac{du}{2x^3} = \frac{1}{2x^3} \int_0^{x^3} e^u du = \frac{1}{2x^3} [e^u]_0^{x^3} = \frac{1}{2x^3} (e^{x^3} - e^0) = \frac{1}{2x^3} (e^{x^3} - 1).$$

Going back to the iterated integral,

$$\int_0^2 x^5 \left[\int_0^1 y e^{x^3 y^2} dy \right] dx = \int_0^2 x^5 \cdot \frac{1}{2x^3} (e^{x^3} - 1) dx = \frac{1}{2} \int_0^2 x^2 (e^{x^3} - 1) dx.$$

Here we make a substitution $v = x^3$; then $dv = 3x^2 dx$, so $x^2 dx = \frac{dv}{3}$. We also change the limits of integration: if $x = 0$, then $v = 0^3 = 0$; if $x = 2$, then $v = 2^3 = 8$. So

$$\begin{aligned} \frac{1}{2} \int_0^2 x^2 (e^{x^3} - 1) dx &= \frac{1}{2} \int_0^8 (e^v - 1) \frac{dv}{3} = \frac{1}{6} \int_0^8 (e^v - 1) dv = \frac{1}{6} [e^v - v]_0^8 \\ &= \frac{1}{6} [(e^8 - 8) - (e^0 - 0)] = \frac{1}{6} (e^8 - 8 - 1 + 0) = \boxed{\frac{1}{6} (e^8 - 9)}. \end{aligned}$$

- (b) Using Fubini's Theorem, we can change the order of integration and also represent the given double integral as

$$\iint_R x^5 y e^{x^3 y^2} dA = \int_0^1 \left[\int_0^2 x^5 y e^{x^3 y^2} dx \right] dy.$$

Entering this iterated integral into the computer algebra system *Mathematica*, we find that

$$\int_0^1 \left[\int_0^2 x^5 y e^{x^3 y^2} dx \right] dy = \boxed{\frac{1}{6} (-9 + e^8)},$$

which agrees with the answer found in part (a).

55. We begin by graphing $z = f(x, y) = x + 2y$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 1$, $0 \leq y \leq 2$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R (x + 2y) dA$. Using Fubini's

Theorem, we have

$$\begin{aligned} V &= \int_0^2 \left[\int_0^1 (x + 2y) dx \right] dy = \int_0^2 \left[\frac{x^2}{2} + 2xy \right]_0^1 dy \\ &= \int_0^2 \left(\frac{1}{2} + 2y \right) dy = \left[\frac{1}{2}y + y^2 \right]_0^2 = (1 + 4) - (0 + 0) = \boxed{5 \text{ cubic units}}. \end{aligned}$$

56. We begin by graphing $z = f(x, y) = 2x + 3y$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 2$, $0 \leq y \leq 3$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R (2x + 3y) dA$. Using

Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^3 \left[\int_0^2 (2x + 3y) dx \right] dy = \int_0^3 [x^2 + 3xy]_0^2 dy \\ &= \int_0^3 (4 + 6y) dy = [4y + 3y^2]_0^3 = (12 + 27) - (0 + 0) = \boxed{39 \text{ cubic units}}. \end{aligned}$$

57. We begin by graphing $z = f(x, y) = x^2 + y^2$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 2$, $0 \leq y \leq 1$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R (x^2 + y^2) dA$. Using

Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^1 \left[\int_0^2 (x^2 + y^2) dx \right] dy = \int_0^1 \left[\frac{x^3}{3} + xy^2 \right]_0^2 dy \\ &= \int_0^1 \left(\frac{8}{3} + 2y^2 \right) dy = \left[\frac{8}{3}y + \frac{2}{3}y^3 \right]_0^1 = \left(\frac{8}{3} + \frac{2}{3} \right) - (0 + 0) = \boxed{\frac{10}{3} \text{ cubic units}}. \end{aligned}$$

58. We begin by graphing $z = f(x, y) = 4x^2 + 3y^2$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 3$, $-2 \leq y \leq 1$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R (4x^2 + 3y^2) dA$. Using

Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^3 \left[\int_{-2}^1 (4x^2 + 3y^2) dy \right] dx = \int_0^3 [4x^2y + y^3]_{-2}^1 dx = \int_0^3 [(4x^2 + 1) - (-8x^2 - 8)] dx \\ &= \int_0^3 (12x^2 + 9) dx = [4x^3 + 9x]_0^3 = (108 + 27) - (0 + 0) = \boxed{135 \text{ cubic units}}. \end{aligned}$$

59. We begin by graphing $z = f(x, y) = \sin x$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq \frac{\pi}{2}$, $0 \leq y \leq 1$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R \sin x dA$. Using Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^1 \left[\int_0^{\pi/2} \sin x dx \right] dy = \int_0^1 [-\cos x]_0^{\pi/2} dy = \int_0^1 \left[-\cos \frac{\pi}{2} + \cos 0 \right] dy \\ &= \int_0^1 (-0 + 1) dy = \int_0^1 1 dy = [y]_0^1 = 1 - 0 = \boxed{1 \text{ cubic unit}}. \end{aligned}$$

60. We begin by graphing $z = f(x, y) = \cos y$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 1$, $0 \leq y \leq \frac{\pi}{2}$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R \cos y dA$. Using Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^1 \left[\int_0^{\pi/2} \cos y dy \right] dx = \int_0^1 [\sin y]_0^{\pi/2} dx = \int_0^1 \left[\sin \frac{\pi}{2} - \sin 0 \right] dx \\ &= \int_0^1 (1 - 0) dx = \int_0^1 1 dx = [x]_0^1 = 1 - 0 = \boxed{1 \text{ cubic unit}}. \end{aligned}$$

61. We begin by graphing $z = f(x, y) = \frac{x^2 + y^2}{xy}$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $1 \leq x \leq 2$, $1 \leq y \leq 2$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA$. Using Fubini's Theorem, we have

$$V = \iint_R \frac{x^2 + y^2}{xy} dA = \int_1^2 \left[\int_1^2 \frac{x^2 + y^2}{xy} dy \right] dx = \int_1^2 \left[\int_1^2 \left(\frac{x}{y} + \frac{y}{x} \right) dy \right] dx.$$

To find the integral in the brackets, we integrate partially with respect to y treating x as a constant:

$$\begin{aligned} \int_1^2 \left(\frac{x}{y} + \frac{y}{x} \right) dy &= \int_1^2 \left(x \cdot \frac{1}{y} + \frac{1}{x} \cdot y \right) dy = \left[x \ln |y| + \frac{1}{x} \cdot \frac{y^2}{2} \right]_1^2 \\ &= \left(x \ln 2 + \frac{2}{x} \right) - \left(x \ln 1 + \frac{1}{2x} \right) = x \ln 2 + \frac{2}{x} - 0 - \frac{1}{2x} = x \ln 2 + \frac{3}{2x}. \end{aligned}$$

Going back to the iterated integral,

$$\begin{aligned}
 V &= \int_1^2 \left[\int_1^2 \left(\frac{x}{y} + \frac{y}{x} \right) dy \right] dx = \int_1^2 \left(x \ln 2 + \frac{3}{2x} \right) dx = \left[\frac{x^2}{2} \cdot \ln 2 + \frac{3}{2} \ln |x| \right]_1^2 \\
 &= \left(2 \ln 2 + \frac{3}{2} \ln 2 \right) - \left(\frac{1}{2} \ln 2 + \frac{3}{2} \ln 1 \right) = 2 \ln 2 + \frac{3}{2} \ln 2 - \frac{1}{2} \ln 2 - 0 = \boxed{3 \ln 2 \text{ cubic units}}.
 \end{aligned}$$

62. We begin by graphing $z = f(x, y) = \frac{y^2}{x^2}$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $1 \leq x \leq 2$, $1 \leq y \leq 2$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA$. Using Fubini's Theorem, we have

$$\begin{aligned}
 V &= \iint_R \frac{y^2}{x^2} dA = \int_1^2 \left[\int_1^2 \frac{y^2}{x^2} dy \right] dx = \int_1^2 \frac{1}{x^2} \left[\int_1^2 y^2 dy \right] dx = \int_1^2 \frac{1}{x^2} \left[\frac{y^3}{3} \right]_1^2 dx \\
 &= \int_1^2 \frac{1}{x^2} \left(\frac{8}{3} - \frac{1}{3} \right) dx = \frac{7}{3} \int_1^2 x^{-2} dx = \frac{7}{3} \left[\frac{x^{-1}}{-1} \right]_1^2 = \frac{7}{3} \left[-\frac{1}{x} \right]_1^2 \\
 &= \frac{7}{3} \left(-\frac{1}{2} + 1 \right) = \frac{7}{3} \cdot \frac{1}{2} = \boxed{\frac{7}{6} \text{ cubic units}}.
 \end{aligned}$$

63. We begin by graphing $z = f(x, y) = e^{x+y}$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 2$, $0 \leq y \leq 1$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R e^{x+y} dA = \iint_R e^x e^y dA$. Using

Fubini's Theorem, we have

$$\begin{aligned}
 V &= \int_0^2 \left[\int_0^1 e^x e^y dy \right] dx = \int_0^2 e^x \left[\int_0^1 e^y dy \right] dx = \int_0^2 e^x [e^y]_0^1 dx = \int_0^2 e^x (e^1 - e^0) dx \\
 &= (e - 1) \int_0^2 e^x dx = (e - 1) [e^x]_0^2 = (e - 1) (e^2 - e^0) = (e - 1) (e^2 - 1) \\
 &= (e - 1)(e - 1)(e + 1) = \boxed{(e - 1)^2(e + 1) \text{ cubic units}}.
 \end{aligned}$$

64. We begin by graphing $z = f(x, y) = e^{x-y}$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 2$, $1 \leq y \leq 2$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R e^{x-y} dA = \iint_R e^x e^{-y} dA$. Using Fubini's Theorem, we have

$$\begin{aligned}
 V &= \int_1^2 \left[\int_0^2 e^x e^{-y} dx \right] dy = \int_1^2 e^{-y} \left[\int_0^2 e^x dx \right] dy \\
 &= \int_1^2 e^{-y} [e^x]_0^2 dy = \int_1^2 e^{-y} (e^2 - e^0) dy = (e^2 - 1) \int_1^2 e^{-y} dy.
 \end{aligned}$$

To complete integration, we make a substitution $u = -y$; then $du = -dy$, so $dy = -du$. We also change the limits of integration: if $y = 1$, then $u = -1$; if $y = 2$, then $u = -2$. So

$$\begin{aligned}
 V &= (e^2 - 1) \int_1^2 e^{-y} dy = (e^2 - 1) \int_{-1}^{-2} e^u (-du) = -(e^2 - 1) \int_{-1}^{-2} e^u du = -(e^2 - 1) [e^u]_{-1}^{-2} \\
 &= -(e^2 - 1)(e^{-2} - e^{-1}) = e - 1 - e^{-1} + e^{-2} = \boxed{e - 1 - \frac{1}{e} + \frac{1}{e^2} \text{ cubic units}}.
 \end{aligned}$$

65. The square in the xy -plane enclosed by the lines $x = \pm 1$ and $y = \pm 1$ can in other words be described as the closed rectangular region $R = \{(x, y) : -1 \leq x \leq 1, -1 \leq y \leq 1\}$. To find the required volume, we begin by graphing the paraboloid $z = f(x, y) = x^2 + y^2$ and the region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the region R , the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R (x^2 + y^2) dA$. Using Fubini's Theorem, we have

$$\begin{aligned} V &= \int_{-1}^1 \left[\int_{-1}^1 (x^2 + y^2) dx \right] dy = \int_{-1}^1 \left[\frac{x^3}{3} + xy^2 \right]_{-1}^1 dy = \int_{-1}^1 \left[\left(\frac{1}{3} + y^2 \right) - \left(-\frac{1}{3} - y^2 \right) \right] dy \\ &= \int_{-1}^1 \left(\frac{2}{3} + 2y^2 \right) dy = \left[\frac{2}{3}y + \frac{2}{3}y^3 \right]_{-1}^1 = \left(\frac{2}{3} + \frac{2}{3} \right) - \left(-\frac{2}{3} - \frac{2}{3} \right) = \boxed{\frac{8}{3} \text{ cubic units}}. \end{aligned}$$

66. Let R be the rectangular region in the xy -plane defined by $a \leq x \leq b$, $c \leq y \leq d$. Let $f(x, y) = 1$ be a function of two variables. Since $z = f(x, y) = 1$ is continuous and $z \geq 0$ over the region R , the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R dA$. Using Fubini's Theorem, we can evaluate this double integral as an iterated integral:

$$\iint_R dA = \int_c^d \left[\int_a^b dx \right] dy = \int_c^d [x]_a^b dy = \int_c^d (b - a) dy = (b - a) \int_c^d dy = (b - a)[y]_c^d = (b - a)(d - c).$$

Challenge Problems

67. (a) Let $z = f(x, y)$ be integrable over a closed rectangular region R of area A . If R is partitioned into N subrectangles of equal area ΔA , the area of each subrectangle is $\Delta A = \frac{A}{N}$, from which $N = \frac{A}{\Delta A}$. If (u_k, v_k) is the center of k th subrectangle, $k = 1, 2, \dots, N$, then the average of the values of f at these points is

$$AVG = \frac{1}{N} \sum_{k=1}^N f(u_k, v_k) = \frac{\Delta A}{A} \sum_{k=1}^N f(u_k, v_k) = \frac{1}{A} \sum_{k=1}^N f(u_k, v_k) \Delta A,$$

where at the last step we used the fact that ΔA is a constant independent of k (all subrectangles have equal area), and so it can be distributed into the summation over k .

- (b) Answers will vary.

68. The area of the rectangular region R defined by $0 \leq x \leq \pi$, $1 \leq y \leq 5$ is $A = 5\pi$. Then by the result of Problem 67, the average value of $f(x, y) = y \cos x$ over R is

$$\begin{aligned} \frac{1}{A} \iint_R f(x, y) dA &= \frac{1}{5\pi} \iint_R y \cos x dA = \frac{1}{5\pi} \int_1^5 \left[\int_0^\pi y \cos x dx \right] dy = \frac{1}{5\pi} \int_1^5 [y \sin x]_0^\pi dy \\ &= \frac{1}{5\pi} \int_1^5 (y \sin \pi - y \sin 0) dy = \frac{1}{5\pi} \int_1^5 0 dy = \frac{1}{5\pi} \cdot 0 = \boxed{0}. \end{aligned}$$

69. The area of the rectangular region R defined by $0 \leq x \leq 1$, $0 \leq y \leq 2$ is $A = 2$. Then by the result of Problem 67, the average value of $f(x, y) = \frac{xy}{x^2 + 1}$ over R is

$$\begin{aligned} \frac{1}{A} \iint_R f(x, y) dA &= \frac{1}{2} \iint_R \frac{xy}{x^2 + 1} dA = \frac{1}{2} \int_0^1 \left[\int_0^2 \frac{xy}{x^2 + 1} dy \right] dx = \frac{1}{2} \int_0^1 \frac{x}{x^2 + 1} \left[\int_0^2 y dy \right] dx \\ &= \frac{1}{2} \int_0^1 \frac{x}{x^2 + 1} \left[\frac{y^2}{2} \right]_0^2 dx = \frac{1}{2} \int_0^1 \frac{x}{x^2 + 1} (2 - 0) dx = \int_0^1 \frac{x}{x^2 + 1} dx. \end{aligned}$$

To complete the integration, we make a substitution $u = x^2 + 1$; then $du = 2x dx$, so $x dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 + 1 = 1$; if $x = 1$, then $u = 1^2 + 1 = 2$. So

$$\int_0^1 \frac{x}{x^2 + 1} dx = \int_1^2 \frac{1}{u} \frac{du}{2} = \frac{1}{2} \int_1^2 \frac{du}{u} = \frac{1}{2} [\ln |u|]_1^2 = \frac{1}{2} (\ln 2 - \ln 1) = \frac{1}{2} (\ln 2 - 0) = \boxed{\frac{\ln 2}{2}}.$$

14.2 The Double Integral over Nonrectangular Regions

Concepts and Vocabulary

- By definition, a closed bounded region R that has a boundary consisting of two smooth curves $y = g_1(x)$ and $y = g_2(x)$, both defined on $a \leq x \leq b$ with $g_1(x) \leq g_2(x)$ on $[a, b]$, and possibly portions of the vertical lines $x = a$ and $x = b$, is called an **x -simple** region.
- True**. If R is a closed bounded y -simple region whose boundary consists of two smooth curves $x = h_1(y)$ and $x = h_2(y)$, both defined on $c \leq y \leq d$ with $h_1(y) \leq h_2(y)$ on $[c, d]$, and possibly portions of the horizontal lines $y = c$ and $y = d$, and if $f(x, y)$ is continuous on R , then

$$\iint_R f(x, y) dA = \int_c^d \left[\int_{h_1(y)}^{h_2(y)} f(x, y) dx \right] dy.$$

- True**. See to the figure below. R is x -simple because it is enclosed by the graphs $y = g_1(x) = x^2 + 1$ and $y = g_2(x) = 3x + 1$ on $0 \leq x \leq 3$, and $g_1(x) \leq g_2(x)$ on $[0, 3]$. R is y -simple because it is enclosed by the graphs $x = h_1(y) = \frac{y-1}{3}$ and $x = h_2(y) = \sqrt{y-1}$ on $1 \leq y \leq 10$, and $h_1(y) \leq h_2(y)$ on $[1, 10]$.

- Answers will vary.

Skill Building

- (a) Observe that the given region R is y -simple: it is bounded by the graphs of $x = h_1(y) = 0$ and $x = h_2(y) = 9 - y^2$ between $y = 1$ and $y = 3$. Using Fubini's Theorem for y -simple regions,

$$\iint_R xy^2 dA = \int_1^3 \left[\int_0^{9-y^2} xy^2 dx \right] dy.$$

- (b) Observe that the given region R is x -simple: it is bounded by the graphs of $y = g_1(x) = 1$ and $y = g_2(x) = \sqrt{9-x}$ between $x = 0$ and $x = 8$. Using Fubini's Theorem for x -simple regions,

$$\iint_R xy^2 dA = \int_0^8 \left[\int_1^{\sqrt{9-x}} xy^2 dy \right] dx.$$

(c) To evaluate the iterated integral in part (a), we first integrate partially with respect to x :

$$\begin{aligned}
 \int_1^3 \left[\int_0^{9-y^2} xy^2 dx \right] dy &= \int_1^3 y^2 \left[\int_0^{9-y^2} x dx \right] dy = \int_1^3 y^2 \left[\frac{x^2}{2} \right]_0^{9-y^2} dy \\
 &= \int_1^3 y^2 \left[\frac{(9-y^2)^2}{2} - \frac{0^2}{2} \right] dy = \int_1^3 y^2 \left(\frac{81}{2} - 9y^2 + \frac{1}{2}y^4 \right) dy \\
 &= \int_1^3 \left(\frac{81}{2}y^2 - 9y^4 + \frac{1}{2}y^6 \right) dy = \left[\frac{27}{2}y^3 - \frac{9}{5}y^5 + \frac{1}{14}y^7 \right]_1^3 \\
 &= \left(\frac{27}{2} \cdot 3^3 - \frac{9}{5} \cdot 3^5 + \frac{1}{14} \cdot 3^7 \right) - \left(\frac{27}{2} \cdot 1^3 - \frac{9}{5} \cdot 1^5 + \frac{1}{14} \cdot 1^7 \right) \\
 &= \frac{729}{2} - \frac{2187}{5} + \frac{2187}{14} - \frac{27}{2} + \frac{9}{5} - \frac{1}{14} = \boxed{\frac{2504}{35}}.
 \end{aligned}$$

To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned}
 \int_0^8 \left[\int_1^{\sqrt{9-x}} xy^2 dy \right] dx &= \int_0^8 x \left[\int_1^{\sqrt{9-x}} y^2 dy \right] dx = \int_0^8 x \left[\frac{y^3}{3} \right]_1^{\sqrt{9-x}} dx \\
 &= \int_0^8 x \left(\frac{(\sqrt{9-x})^3}{3} - \frac{1}{3} \right) dx = \frac{1}{3} \int_0^8 x(9-x)^{3/2} dx - \frac{1}{3} \int_0^8 x dx.
 \end{aligned}$$

The second integral can be evaluated directly as

$$\frac{1}{3} \int_0^8 x dx = \frac{1}{3} \left[\frac{x^2}{2} \right]_0^8 = \frac{1}{3}(32 - 0) = \frac{32}{3}.$$

To evaluate the first integral, we make a substitution $u = 9 - x$, so that $x = 9 - u$; then $du = -dx$, so $dx = -du$. We also change the limits of integration: if $x = 0$, then $u = 9 - 0 = 9$; if $x = 8$, then $u = 9 - 8 = 1$. So

$$\begin{aligned}
 \frac{1}{3} \int_0^8 x(9-x)^{3/2} dx &= \frac{1}{3} \int_9^1 (9-u)u^{3/2}(-du) = -\frac{1}{3} \int_9^1 (9-u)u^{3/2} du = \frac{1}{3} \int_1^9 (9-u)u^{3/2} du \\
 &= \frac{1}{3} \int_1^9 (9u^{3/2} - u^{5/2}) du = \frac{1}{3} \left[9 \cdot \frac{u^{5/2}}{5/2} - \frac{u^{7/2}}{7/2} \right]_1^9 = \left[\frac{6}{5}(\sqrt{u})^5 - \frac{2}{21}(\sqrt{u})^7 \right]_1^9 \\
 &= \left(\frac{6}{5}(\sqrt{9})^5 - \frac{2}{21}(\sqrt{9})^7 \right) - \left(\frac{6}{5}(\sqrt{1})^5 - \frac{2}{21}(\sqrt{1})^7 \right) \\
 &= \frac{1458}{5} - \frac{1458}{7} - \frac{6}{5} + \frac{2}{21} = \frac{8632}{105}.
 \end{aligned}$$

The final answer is

$$\frac{1}{3} \int_0^8 x(9-x)^{3/2} dx - \frac{1}{3} \int_0^8 x dx = \frac{8632}{105} - \frac{32}{3} = \boxed{\frac{2504}{35}}.$$

6. (a) Observe that the given region R is y -simple: it is bounded by the graphs of $x = h_1(y) = y^2$ and $x = h_2(y) = \sqrt[3]{y}$ between $y = 0$ and $y = 1$. Using Fubini's Theorem for y -simple regions,

$$\iint_R xy^2 dA = \int_0^1 \left[\int_{y^2}^{\sqrt[3]{y}} xy^2 dx \right] dy.$$

- (b) Observe that the given region R is x -simple: it is bounded by the graphs of $y = g_1(x) = x^3$ and $y = g_2(x) = \sqrt{x}$ between $x = 0$ and $x = 1$. Using Fubini's Theorem for x -simple regions,

$$\iint_R xy^2 dA = \boxed{\int_0^1 \left[\int_{x^3}^{\sqrt{x}} xy^2 dy \right] dx}.$$

- (c) To evaluate the iterated integral in part (a), we first integrate partially with respect to x :

$$\begin{aligned} \int_0^1 \left[\int_{y^2}^{\sqrt[3]{y}} xy^2 dx \right] dy &= \int_0^1 y^2 \left[\int_{y^2}^{\sqrt[3]{y}} x dx \right] dy = \int_0^1 y^2 \left[\frac{x^2}{2} \right]_{y^2}^{\sqrt[3]{y}} dy \\ &= \int_0^1 y^2 \left[\frac{(\sqrt[3]{y})^2}{2} - \frac{(y^2)^2}{2} \right] dy = \frac{1}{2} \int_0^1 y^2 (y^{2/3} - y^4) dy \\ &= \frac{1}{2} \int_0^1 (y^{8/3} - y^6) dy = \frac{1}{2} \left[\frac{y^{11/3}}{11/3} - \frac{y^7}{7} \right]_0^1 = \frac{1}{2} \left[\frac{3}{11} y^{11/3} - \frac{1}{7} y^7 \right]_0^1 \\ &= \frac{1}{2} \left[\left(\frac{3}{11} - \frac{1}{7} \right) - (0 - 0) \right] = \frac{1}{2} \cdot \frac{10}{77} = \boxed{\frac{5}{77}}. \end{aligned}$$

To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_{x^3}^{\sqrt{x}} xy^2 dy \right] dx &= \int_0^1 x \left[\int_{x^3}^{\sqrt{x}} y^2 dy \right] dx = \int_0^1 x \left[\frac{y^3}{3} \right]_{x^3}^{\sqrt{x}} dx \\ &= \int_0^1 x \left[\frac{(\sqrt{x})^3}{3} - \frac{(x^3)^3}{3} \right] dx = \frac{1}{3} \int_0^1 x (x^{3/2} - x^9) dx \\ &= \frac{1}{3} \int_0^1 (x^{5/2} - x^{10}) dx = \frac{1}{3} \left[\frac{x^{7/2}}{7/2} - \frac{x^{11}}{11} \right]_0^1 = \frac{1}{3} \left[\frac{2}{7} x^{7/2} - \frac{1}{11} x^{11} \right]_0^1 \\ &= \frac{1}{3} \left[\left(\frac{2}{7} - \frac{1}{11} \right) - (0 - 0) \right] = \frac{1}{3} \cdot \frac{15}{77} = \boxed{\frac{5}{77}}. \end{aligned}$$

7. (a) Observe that the given region R is y -simple: it is bounded by the graphs of $x = h_1(y) = 3 - y$ and $x = h_2(y) = \sqrt{9 - y^2}$ between $y = 0$ and $y = 3$. Using Fubini's Theorem for y -simple regions,

$$\iint_R xy^2 dA = \boxed{\int_0^3 \left[\int_{3-y}^{\sqrt{9-y^2}} xy^2 dx \right] dy}.$$

- (b) Observe that the given region R is x -simple: it is bounded by the graphs of $y = g_1(x) = 3 - x$ and $y = g_2(x) = \sqrt{9 - x^2}$ between $x = 0$ and $x = 3$. Using Fubini's Theorem for x -simple regions,

$$\iint_R xy^2 dA = \boxed{\int_0^3 \left[\int_{3-x}^{\sqrt{9-x^2}} xy^2 dy \right] dx}.$$

(c) To evaluate the iterated integral in part (a), we first integrate partially with respect to x :

$$\begin{aligned}
 \int_0^3 \left[\int_{3-y}^{\sqrt{9-y^2}} xy^2 dx \right] dy &= \int_0^3 y^2 \left[\int_{3-y}^{\sqrt{9-y^2}} x dx \right] dy = \int_0^3 y^2 \left[\frac{x^2}{2} \right]_{3-y}^{\sqrt{9-y^2}} dy \\
 &= \int_0^3 y^2 \left[\frac{(\sqrt{9-y^2})^2}{2} - \frac{(3-y)^2}{2} \right] dy \\
 &= \int_0^3 y^2 \cdot \frac{1}{2} [(9-y^2) - (9-6y+y^2)] dy \\
 &= \int_0^3 y^2 \cdot \frac{1}{2} (6y-2y^2) dy = \int_0^3 (3y^3 - y^4) dy \\
 &= \left[\frac{3}{4}y^4 - \frac{1}{5}y^5 \right]_0^3 = \left(\frac{3}{4} \cdot 3^4 - \frac{1}{5} \cdot 3^5 \right) - \left(\frac{3}{4} \cdot 0^4 - \frac{1}{5} \cdot 0^5 \right) \\
 &= \left(\frac{243}{4} - \frac{243}{5} \right) - 0 = \boxed{\frac{243}{20}}.
 \end{aligned}$$

To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned}
 \int_0^3 \left[\int_{3-x}^{\sqrt{9-x^2}} xy^2 dy \right] dx &= \int_0^3 x \left[\int_{3-x}^{\sqrt{9-x^2}} y^2 dy \right] dx = \int_0^3 x \left[\frac{y^3}{3} \right]_{3-x}^{\sqrt{9-x^2}} dx \\
 &= \int_0^3 x \left[\frac{(\sqrt{9-x^2})^3}{3} - \frac{(3-x)^3}{3} \right] dx \\
 &= \frac{1}{3} \int_0^3 x (\sqrt{9-x^2})^3 dx - \frac{1}{3} \int_0^3 x(3-x)^3 dx.
 \end{aligned}$$

The second integral can be evaluated directly as

$$\begin{aligned}
 \frac{1}{3} \int_0^3 x(3-x)^3 dx &= \frac{1}{3} \int_0^3 x(27-27x+9x^2-x^3) dx = \int_0^3 \left(9x-9x^2+3x^3-\frac{1}{3}x^4 \right) dx \\
 &= \left[\frac{9}{2}x^2-3x^3+\frac{3}{4}x^4-\frac{1}{15}x^5 \right]_0^3 = \left(\frac{9}{2} \cdot 3^2 - 3 \cdot 3^3 + \frac{3}{4} \cdot 3^4 - \frac{1}{15} \cdot 3^5 \right) - 0 \\
 &= \frac{81}{2} - 81 + \frac{243}{4} - \frac{81}{5} = \frac{81}{20}.
 \end{aligned}$$

To evaluate the first integral, we make a substitution $u = 9 - x^2$; then $du = -2x dx$, so $x dx = \frac{du}{-2}$. We also change the limits of integration: if $x = 0$, then $u = 9 - 0^2 = 9$; if $x = 3$, then $u = 9 - 3^2 = 0$. So

$$\begin{aligned}
 \frac{1}{3} \int_0^3 x (\sqrt{9-x^2})^3 dx &= \frac{1}{3} \int_9^0 (\sqrt{u})^3 \frac{du}{-2} = -\frac{1}{6} \int_9^0 u^{3/2} du = \frac{1}{6} \int_0^9 u^{3/2} du = \frac{1}{6} \left[\frac{u^{5/2}}{5/2} \right]_0^9 \\
 &= \frac{1}{15} [(\sqrt{u})^5]_0^9 = \frac{1}{15} \left((\sqrt{9})^5 - (\sqrt{0})^5 \right) = \frac{1}{15} \cdot 243 = \frac{81}{5}.
 \end{aligned}$$

The final answer is

$$\frac{1}{3} \int_0^3 x (\sqrt{9-x^2})^3 dx - \frac{1}{3} \int_0^3 x(3-x)^3 dx = \frac{81}{5} - \frac{81}{20} = \boxed{\frac{243}{20}}.$$

8. (a) Observe that the given region R is y -simple: it is bounded by the graphs of $x = h_1(y) = \frac{y}{4}$ and $x = h_2(y) = \sqrt[3]{y}$ between $y = 0$ and $y = 8$. Using Fubini's Theorem for y -simple regions,

$$\iint_R xy^2 dA = \int_0^8 \left[\int_{y/4}^{\sqrt[3]{y}} xy^2 dx \right] dy.$$

- (b) Observe that the given region R is x -simple: it is bounded by the graphs of $y = g_1(x) = x^3$ and $y = g_2(x) = 4x$ between $x = 0$ and $x = 2$. Using Fubini's Theorem for x -simple regions,

$$\iint_R xy^2 dA = \int_0^2 \left[\int_{x^3}^{4x} xy^2 dy \right] dx.$$

- (c) To evaluate the iterated integral in part (a), we first integrate partially with respect to x :

$$\begin{aligned} \int_0^8 \left[\int_{y/4}^{\sqrt[3]{y}} xy^2 dx \right] dy &= \int_0^8 y^2 \left[\int_{y/4}^{\sqrt[3]{y}} x dx \right] dy = \int_0^8 y^2 \left[\frac{x^2}{2} \right]_{y/4}^{\sqrt[3]{y}} dy \\ &= \int_0^8 y^2 \left[\frac{(\sqrt[3]{y})^2}{2} - \frac{(y/4)^2}{2} \right] dy = \int_0^8 y^2 \left(\frac{1}{2} y^{2/3} - \frac{1}{32} y^2 \right) dy \\ &= \int_0^8 \left(\frac{1}{2} y^{8/3} - \frac{1}{32} y^4 \right) dy = \left[\frac{1}{2} \cdot \frac{y^{11/3}}{11/3} - \frac{1}{32} \cdot \frac{y^5}{5} \right]_0^8 \\ &= \left[\frac{3}{22} (\sqrt[3]{y})^{11} - \frac{1}{160} y^5 \right]_0^8 \\ &= \left(\frac{3}{22} \cdot (\sqrt[3]{8})^{11} - \frac{1}{160} \cdot 8^5 \right) - \left(\frac{3}{22} \cdot (\sqrt[3]{0})^{11} - \frac{1}{160} \cdot 0^5 \right) \\ &= \left(\frac{3072}{11} - \frac{1024}{5} \right) - 0 = \boxed{\frac{4096}{55}}. \end{aligned}$$

To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned} \int_0^2 \left[\int_{x^3}^{4x} xy^2 dy \right] dx &= \int_0^2 x \left[\int_{x^3}^{4x} y^2 dy \right] dx = \int_0^2 x \left[\frac{y^3}{3} \right]_{x^3}^{4x} dx \\ &= \int_0^2 x \left[\frac{(4x)^3}{3} - \frac{(x^3)^3}{3} \right] dx = \int_0^2 x \left(\frac{64}{3} x^3 - \frac{1}{3} x^9 \right) dx \\ &= \int_0^2 \left(\frac{64}{3} x^4 - \frac{1}{3} x^{10} \right) dx = \left[\frac{64}{3} \cdot \frac{x^5}{5} - \frac{1}{3} \cdot \frac{x^{11}}{11} \right]_0^2 = \left[\frac{64}{15} x^5 - \frac{1}{33} x^{11} \right]_0^2 \\ &= \left(\frac{64}{15} \cdot 2^5 - \frac{1}{33} \cdot 2^{11} \right) - \left(\frac{64}{15} \cdot 0^5 - \frac{1}{33} \cdot 0^{11} \right) \\ &= \left(\frac{2048}{15} - \frac{2048}{33} \right) - 0 = \boxed{\frac{4096}{55}}. \end{aligned}$$

9. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_{x^2}^{\sqrt{x}} dy \right] dx &= \int_0^1 [y]_{x^2}^{\sqrt{x}} dx = \int_0^1 (\sqrt{x} - x^2) dx = \int_0^1 (x^{1/2} - x^2) dx \\ &= \left[\frac{x^{3/2}}{3/2} - \frac{x^3}{3} \right]_0^1 = \left[\frac{2}{3} x^{3/2} - \frac{1}{3} x^3 \right]_0^1 = \left(\frac{2}{3} - \frac{1}{3} \right) - (0 - 0) = \boxed{\frac{1}{3}}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = x^2$ and $y = g_2(x) = \sqrt{x}$ between $x = 0$ and $x = 1$.

10. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned} \int_0^1 \left[\int_{y^2}^{\sqrt{y}} x \, dx \right] dy &= \int_0^1 \left[\frac{x^2}{2} \right]_{y^2}^{\sqrt{y}} dy = \int_0^1 \left[\frac{(\sqrt{y})^2}{2} - \frac{(y^2)^2}{2} \right] dy = \frac{1}{2} \int_0^1 (y - y^4) dy \\ &= \frac{1}{2} \left[\frac{y^2}{2} - \frac{y^5}{5} \right]_0^1 = \frac{1}{2} \left[\left(\frac{1}{2} - \frac{1}{5} \right) - (0 - 0) \right] = \frac{1}{2} \cdot \frac{3}{10} = \boxed{\frac{3}{20}}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = y^2$ and $x = h_2(y) = \sqrt{y}$ between $y = 0$ and $y = 1$.

11. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned} \int_{-1}^2 \left[\int_{y^2}^{y+2} dx \right] dy &= \int_{-1}^2 [x]_{y^2}^{y+2} dy = \int_{-1}^2 (y + 2 - y^2) dy = \left[\frac{y^2}{2} + 2y - \frac{y^3}{3} \right]_{-1}^2 \\ &= \left(\frac{2^2}{2} + 2 \cdot 2 - \frac{2^3}{3} \right) - \left(\frac{(-1)^2}{2} + 2 \cdot (-1) - \frac{(-1)^3}{3} \right) \\ &= 2 + 4 - \frac{8}{3} - \frac{1}{2} + 2 - \frac{1}{3} = \boxed{\frac{9}{2}}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = y^2$ and $x = h_2(y) = y + 2$ between $y = -1$ and $y = 2$.

12. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_x^{2x} y \, dy \right] dx &= \int_0^1 \left[\frac{y^2}{2} \right]_x^{2x} dx = \int_0^1 \left[\frac{(2x)^2}{2} - \frac{x^2}{2} \right] dx \\ &= \int_0^1 \left(\frac{4x^2}{2} - \frac{x^2}{2} \right) dx = \int_0^1 \frac{3}{2} x^2 \, dx = \left[\frac{1}{2} x^3 \right]_0^1 = \frac{1}{2} - 0 = \boxed{\frac{1}{2}}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = x$ and $y = g_2(x) = 2x$ between $x = 0$ and $x = 1$.

13. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_x^{3x} xy \, dy \right] dx &= \int_0^1 x \left[\int_x^{3x} y \, dy \right] dx = \int_0^1 x \left[\frac{y^2}{2} \right]_x^{3x} dx = \int_0^1 x \left[\frac{(3x)^2}{2} - \frac{x^2}{2} \right] dx \\ &= \int_0^1 x \left(\frac{9x^2}{2} - \frac{x^2}{2} \right) dx = \int_0^1 x \cdot 4x^2 \, dx = \int_0^1 4x^3 \, dx = \left[x^4 \right]_0^1 = 1 - 0 = \boxed{1}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = x$ and $y = g_2(x) = 3x$ between $x = 0$ and $x = 1$.

14. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned} \int_0^1 \left[\int_y^{\sqrt{y}} x^2 y \, dx \right] dy &= \int_0^1 y \left[\int_y^{\sqrt{y}} x^2 \, dx \right] dy = \int_0^1 y \left[\frac{x^3}{3} \right]_y^{\sqrt{y}} dy = \int_0^1 y \left[\frac{(\sqrt{y})^3}{3} - \frac{y^3}{3} \right] dy \\ &= \frac{1}{3} \int_0^1 y (y^{3/2} - y^3) dy = \frac{1}{3} \int_0^1 (y^{5/2} - y^4) dy = \frac{1}{3} \left[\frac{y^{7/2}}{7/2} - \frac{y^5}{5} \right]_0^1 \\ &= \frac{1}{3} \left[\frac{2}{7} y^{7/2} - \frac{1}{5} y^5 \right]_0^1 = \frac{1}{3} \left[\left(\frac{2}{7} - \frac{1}{5} \right) - (0 - 0) \right] = \frac{1}{3} \cdot \frac{3}{35} = \boxed{\frac{1}{35}}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = y$ and $x = h_2(y) = \sqrt{y}$ between $y = 0$ and $y = 1$.

15. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned} \int_0^1 \left[\int_1^{e^y} \frac{y}{x} \, dx \right] dy &= \int_0^1 y \left[\int_1^{e^y} \frac{1}{x} \, dx \right] dy = \int_0^1 y [\ln |x|]_1^{e^y} dy \\ &= \int_0^1 y (\ln e^y - \ln 1) dy = \int_0^1 y(y - 0) dy = \int_0^1 y^2 dy = \left[\frac{y^3}{3} \right]_0^1 = \frac{1}{3} - 0 = \boxed{\frac{1}{3}}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = 1$ and $x = h_2(y) = e^y$ between $y = 0$ and $y = 1$.

16. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_0^{x^2} x e^y \, dy \right] dx &= \int_0^1 x \left[\int_0^{x^2} e^y \, dy \right] dx = \int_0^1 x [e^y]_0^{x^2} dx \\ &= \int_0^1 x (e^{x^2} - e^0) dx = \int_0^1 x (e^{x^2} - 1) dx = \int_0^1 x e^{x^2} dx - \int_0^1 x dx. \end{aligned}$$

The second integral can be evaluated directly as $\int_0^1 x \, dx = \left[\frac{x^2}{2} \right]_0^1 = \frac{1}{2} - 0 = \frac{1}{2}$.

To evaluate the first integral, we make a substitution $u = x^2$; then $du = 2x \, dx$, so $x \, dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 = 0$; if $x = 1$, then $u = 1^2 = 1$. So

$$\int_0^1 x e^{x^2} \, dx = \int_0^1 e^u \frac{du}{2} = \frac{1}{2} \int_0^1 e^u \, du = \frac{1}{2} [e^u]_0^1 = \frac{1}{2} (e^1 - e^0) = \frac{1}{2} (e - 1) = \frac{1}{2}e - \frac{1}{2}.$$

Then the final answer is

$$\int_0^1 x e^{x^2} \, dx - \int_0^1 x \, dx = \frac{1}{2}e - \frac{1}{2} - \frac{1}{2} = \boxed{\frac{1}{2}e - 1}.$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = 0$ and $y = g_2(x) = x^2$ between $x = 0$ and $x = 1$.

17. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned} \int_0^2 \left[\int_y^{2y} xy \, dx \right] dy &= \int_0^2 y \left[\int_y^{2y} x \, dx \right] dy = \int_0^2 y \left[\frac{x^2}{2} \right]_y^{2y} dy = \int_0^2 y \left(\frac{(2y)^2}{2} - \frac{y^2}{2} \right) dy \\ &= \int_0^2 y \cdot \frac{3}{2} y^2 \, dy = \int_0^2 \frac{3}{2} y^3 \, dy = \left[\frac{3}{8} y^4 \right]_0^2 = \frac{3}{8} \cdot 2^4 - \frac{3}{8} \cdot 0^4 = 6 - 0 = \boxed{6}. \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = y$ and $x = h_2(y) = 2y$ between $y = 0$ and $y = 2$.

18. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned}
 \int_2^4 \left[\int_1^{y^2} \frac{y}{x^2} dx \right] dy &= \int_2^4 y \left[\int_1^{y^2} \frac{1}{x^2} dx \right] dy = \int_2^4 y \left[\int_1^{y^2} x^{-2} dx \right] dy = \int_2^4 y \left[\frac{x^{-1}}{-1} \right]_1^{y^2} dy \\
 &= \int_2^4 y \left[-\frac{1}{x} \right]_1^{y^2} dy = \int_2^4 y \left(-\frac{1}{y^2} + \frac{1}{1} \right) dy = \int_2^4 y \left(1 - \frac{1}{y^2} \right) dy \\
 &= \int_2^4 \left(y - \frac{1}{y} \right) dy = \left[\frac{y^2}{2} - \ln |y| \right]_2^4 = \left(\frac{4^2}{2} - \ln 4 \right) - \left(\frac{2^2}{2} - \ln 2 \right) \\
 &= 8 - \ln 4 - 2 + \ln 2 = \boxed{6 - \ln 2}.
 \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = 1$ and $x = h_2(y) = y^2$ between $y = 2$ and $y = 4$.

19. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned}
 \int_0^1 \left[\int_{x^2}^x \sqrt{xy} dy \right] dx &= \int_0^1 \left[\int_{x^2}^x \sqrt{x} \sqrt{y} dy \right] dx = \int_0^1 x^{1/2} \left[\int_{x^2}^x y^{1/2} dy \right] dx = \int_0^1 x^{1/2} \left[\frac{y^{3/2}}{3/2} \right]_{x^2}^x dx \\
 &= \frac{2}{3} \int_0^1 x^{1/2} \left(x^{3/2} - (x^2)^{3/2} \right) dx = \frac{2}{3} \int_0^1 x^{1/2} \left(x^{3/2} - x^3 \right) dx \\
 &= \frac{2}{3} \int_0^1 \left(x^2 - x^{7/2} \right) dx = \frac{2}{3} \left[\frac{x^3}{3} - \frac{x^{9/2}}{9/2} \right]_0^1 = \frac{2}{3} \left[\frac{1}{3} x^3 - \frac{2}{9} x^{9/2} \right]_0^1 \\
 &= \frac{2}{3} \left[\left(\frac{1}{3} - \frac{2}{9} \right) - (0 - 0) \right] = \frac{2}{3} \cdot \frac{1}{9} = \boxed{\frac{2}{27}}.
 \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = x^2$ and $y = g_2(x) = x$ between $x = 0$ and $x = 1$.

20. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned}\int_0^1 \left[\int_{x^2}^x \sqrt{x} \, dy \right] dx &= \int_0^1 x^{1/2} \left[\int_{x^2}^x dy \right] dx = \int_0^1 x^{1/2} [y]_{x^2}^x dx = \int_0^1 x^{1/2} (x - x^2) dx \\ &= \int_0^1 (x^{3/2} - x^{5/2}) dx = \left[\frac{x^{5/2}}{5/2} - \frac{x^{7/2}}{7/2} \right]_0^1 = \left[\frac{2}{5} x^{5/2} - \frac{2}{7} x^{7/2} \right]_0^1 \\ &= \left[\left(\frac{2}{5} - \frac{2}{7} \right) - (0 - 0) \right] = \boxed{\frac{4}{35}}.\end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = x^2$ and $y = g_2(x) = x$ between $x = 0$ and $x = 1$.

21. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned}\int_0^1 \left[\int_x^1 \frac{1}{x^2 + 1} dy \right] dx &= \int_0^1 \frac{1}{x^2 + 1} \left[\int_x^1 dy \right] dx = \int_0^1 \frac{1}{x^2 + 1} [y]_x^1 dx \\ &= \int_0^1 \frac{1}{x^2 + 1} (1 - x) dx = \int_0^1 \frac{1}{x^2 + 1} dx - \int_0^1 \frac{x}{x^2 + 1} dx.\end{aligned}$$

The first integral can be evaluated directly as

$$\int_0^1 \frac{1}{x^2 + 1} dx = [\tan^{-1}(x)]_0^1 = \tan^{-1}(1) - \tan^{-1}(0) = \frac{\pi}{4} - 0 = \frac{\pi}{4}.$$

To evaluate the second integral, we make a substitution $u = x^2 + 1$; then $du = 2x dx$, so $x dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 + 1 = 1$; if $x = 1$, then $u = 1^2 + 1 = 2$. So

$$\int_0^1 \frac{x}{x^2 + 1} dx = \int_1^2 \frac{1}{u} \frac{du}{2} = \frac{1}{2} \int_1^2 \frac{1}{u} du = \frac{1}{2} [\ln |u|]_1^2 = \frac{1}{2} (\ln 2 - \ln 1) = \frac{1}{2} (\ln 2 - 0) = \frac{\ln 2}{2}.$$

Then the final answer is

$$\int_0^1 \frac{1}{x^2 + 1} dx - \int_0^1 \frac{x}{x^2 + 1} dx = \boxed{\frac{\pi}{4} - \frac{\ln 2}{2}}.$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = x$ and $y = g_2(x) = 1$ between $x = 0$ and $x = 1$.

22. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\begin{aligned}
 \int_0^1 \left[\int_y^{\sqrt{y}} (x^2 + y^2) dx \right] dy &= \int_0^1 \left[\frac{x^3}{3} + xy^2 \right]_y^{\sqrt{y}} dy = \int_0^1 \left[\left(\frac{\sqrt{y}^3}{3} + \sqrt{y}y^2 \right) - \left(\frac{y^3}{3} + yy^2 \right) \right] dy \\
 &= \int_0^1 \left(\frac{1}{3}y^{3/2} + y^{5/2} - \frac{4}{3}y^3 \right) dy = \left[\frac{1}{3} \cdot \frac{y^{5/2}}{5/2} + \frac{y^{7/2}}{7/2} - \frac{4}{3} \cdot \frac{y^4}{4} \right]_0^1 \\
 &= \left[\frac{2}{15}y^{5/2} + \frac{2}{7}y^{7/2} - \frac{1}{3}y^4 \right]_0^1 = \left(\frac{2}{15} + \frac{2}{7} - \frac{1}{3} \right) - 0 = \boxed{\frac{3}{35}}.
 \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = y$ and $x = h_2(y) = \sqrt{y}$ between $y = 0$ and $y = 1$.

23. To evaluate this iterated integral, we first integrate partially with respect to y :

$$\begin{aligned}
 \int_1^2 \left[\int_0^{\ln x} xe^y dy \right] dx &= \int_1^2 x \left[\int_0^{\ln x} e^y dy \right] dx = \int_1^2 x [e^y]_0^{\ln x} dx = \int_1^2 x (e^{\ln x} - e^0) dx \\
 &= \int_1^2 x(x - 1) dx = \int_1^2 (x^2 - x) dx = \left[\frac{x^3}{3} - \frac{x^2}{2} \right]_1^2 \\
 &= \left(\frac{8}{3} - 2 \right) - \left(\frac{1}{3} - \frac{1}{2} \right) = \boxed{\frac{5}{6}}.
 \end{aligned}$$

The graph of the region R is shown below. It is bounded by the graphs of $y = g_1(x) = 0$ and $y = g_2(x) = \ln x$ between $x = 1$ and $x = 2$.

24. To evaluate this iterated integral, we first integrate partially with respect to x :

$$\int_2^3 \left[\int_0^{1/y} \ln y \, dx \right] dy = \int_2^3 \ln y \left[\int_0^{1/y} dx \right] dy = \int_2^3 \ln y [x]_0^{1/y} dy = \int_2^3 \ln y \left(\frac{1}{y} - 0 \right) dy = \int_2^3 \frac{\ln y}{y} dy.$$

To evaluate this integral, we make a substitution $u = \ln y$; then $du = \frac{1}{y} dy$. We also change the limits of integration: if $y = 2$, then $u = \ln 2$; if $y = 3$, then $u = \ln 3$. So

$$\int_2^3 \frac{\ln y}{y} dy = \int_{\ln 2}^{\ln 3} u \, du = \left[\frac{u^2}{2} \right]_{\ln 2}^{\ln 3} = \boxed{\frac{(\ln 3)^2 - (\ln 2)^2}{2}}.$$

The graph of the region R is shown below. It is bounded by the graphs of $x = h_1(y) = 0$ and $x = h_2(y) = \frac{1}{y}$ between $y = 2$ and $y = 3$.

25. We begin by graphing the region R enclosed by $y = x^2$ and $y^2 = 8x$; see the figure below. Observe that R is a closed bounded region, that is x -simple: it is bounded by the graphs of $y = g_1(x) = x^2$ and

$y = g_2(x) = \sqrt{8x}$ between $x = 0$ and $x = 2$. So we can apply Fubini's Theorem for x -simple regions:

$$\begin{aligned}
 \iint_R (x+y) \, dA &= \int_0^2 \left[\int_{x^2}^{\sqrt{8x}} (x+y) \, dy \right] dx = \int_0^2 \left[xy + \frac{y^2}{2} \right]_{x^2}^{\sqrt{8x}} dx \\
 &= \int_0^2 \left[\left(x\sqrt{8x} + \frac{(\sqrt{8x})^2}{2} \right) - \left(xx^2 + \frac{(x^2)^2}{2} \right) \right] dx \\
 &= \int_0^2 \left(\sqrt{8}x^{3/2} + 4x - x^3 - \frac{1}{2}x^4 \right) dx \\
 &= \left[2\sqrt{2} \cdot \frac{x^{5/2}}{5/2} + 4 \cdot \frac{x^2}{2} - \frac{x^4}{4} - \frac{1}{2} \cdot \frac{x^5}{5} \right]_0^2 = \left[\frac{4\sqrt{2}}{5} (\sqrt{x})^5 + 2x^2 - \frac{1}{4}x^4 - \frac{1}{10}x^5 \right]_0^2 \\
 &= \left(\frac{4\sqrt{2}}{5} (\sqrt{2})^5 + 2 \cdot 2^2 - \frac{1}{4} \cdot 2^4 - \frac{1}{10} \cdot 2^5 \right) - 0 = \frac{32}{5} + 8 - 4 - \frac{16}{5} = \boxed{\frac{36}{5}}.
 \end{aligned}$$

26. We begin by graphing the region R enclosed by $y = x$ and $y = x^2$; see the figure below. Observe that R is a closed bounded region, that is x -simple: it is bounded by the graphs of $y = g_1(x) = x^2$ and $y = g_2(x) = x$ between $x = 0$ and $x = 1$. So we can apply Fubini's Theorem for x -simple regions:

$$\begin{aligned}
 \iint_R (x^2 - y^2) \, dA &= \int_0^1 \left[\int_{x^2}^x (x^2 - y^2) \, dy \right] dx = \int_0^1 \left[x^2y - \frac{y^3}{3} \right]_{x^2}^x dx \\
 &= \int_0^1 \left[\left(x^2x - \frac{x^3}{3} \right) - \left(x^2x^2 - \frac{(x^2)^3}{3} \right) \right] dx = \int_0^1 \left(\frac{2}{3}x^3 - x^4 + \frac{1}{3}x^6 \right) dx \\
 &= \left[\frac{2}{3} \cdot \frac{x^4}{4} - \frac{x^5}{5} + \frac{1}{3} \cdot \frac{x^7}{7} \right]_0^1 = \left[\frac{1}{6}x^4 - \frac{1}{5}x^5 + \frac{1}{21}x^7 \right]_0^1 \\
 &= \left(\frac{1}{6} - \frac{1}{5} + \frac{1}{21} \right) - 0 = \boxed{\frac{1}{70}}.
 \end{aligned}$$

27. We begin by graphing the region R enclosed by $y = 2 - x$ and $y = x^2$; see the figure below. Observe that R is a closed bounded region, that is x -simple: it is bounded by the graphs of $y = g_1(x) = x^2$ and $y = g_2(x) = 2 - x$ between $x = -2$ and $x = 1$. So we can apply Fubini's Theorem for x -simple regions:

$$\begin{aligned}
 \iint_R y^2 dA &= \int_{-2}^1 \left[\int_{x^2}^{2-x} y^2 dy \right] dx = \int_{-2}^1 \left[\frac{y^3}{3} \right]_{x^2}^{2-x} dx = \int_{-2}^1 \frac{1}{3} [(2-x)^3 - (x^2)^3] dx \\
 &= \int_{-2}^1 \frac{1}{3} (8 - 12x + 6x^2 - x^3 - x^6) dx = \int_{-2}^1 \left(\frac{8}{3} - 4x + 2x^2 - \frac{1}{3}x^3 - \frac{1}{3}x^6 \right) dx \\
 &= \left[\frac{8}{3}x - 2x^2 + \frac{2}{3}x^3 - \frac{1}{12}x^4 - \frac{1}{21}x^7 \right]_{-2}^1 \\
 &= \left(\frac{8}{3} - 2 + \frac{2}{3} - \frac{1}{12} - \frac{1}{21} \right) - \left(-\frac{16}{3} - 8 - \frac{16}{3} - \frac{4}{3} + \frac{128}{21} \right) = \boxed{\frac{423}{28}}.
 \end{aligned}$$

28. We begin by graphing the region R enclosed by $y^2 = x + 1$ and $y = 1 - x$; see the figure below. Observe that R is a closed bounded region, that is y -simple: it is bounded by the graphs of $x = h_1(y) = y^2 - 1$ and $x = h_2(y) = 1 - y$ between $y = -2$ and $y = 1$. So we can apply Fubini's Theorem for y -simple regions:

$$\begin{aligned}
 \iint_R xy dA &= \int_{-2}^1 \left[\int_{y^2-1}^{1-y} xy dx \right] dy = \int_{-2}^1 y \left[\int_{y^2-1}^{1-y} x dx \right] dy = \int_{-2}^1 y \left[\frac{x^2}{2} \right]_{y^2-1}^{1-y} dy \\
 &= \int_{-2}^1 \frac{1}{2} y [(1-y)^2 - (y^2-1)^2] dy = \int_{-2}^1 \frac{1}{2} y [(1-2y+y^2) - (y^4-2y^2+1)] dy \\
 &= \int_{-2}^1 \frac{1}{2} y (-y^4 + 3y^2 - 2y) dy = \int_{-2}^1 \left(-\frac{1}{2}y^5 + \frac{3}{2}y^3 - y^2 \right) dy \\
 &= \left[-\frac{1}{12}y^6 + \frac{3}{8}y^4 - \frac{1}{3}y^3 \right]_{-2}^1 = \left(-\frac{1}{12} + \frac{3}{8} - \frac{1}{3} \right) - \left(-\frac{16}{3} + 6 + \frac{8}{3} \right) = \boxed{-\frac{27}{8}}.
 \end{aligned}$$

29. We begin by graphing the region R enclosed by the graphs of $y = x^3$ and $y = x^2$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = x^3$ to $y = x^2$, $0 \leq x \leq 1$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_0^1 \left[\int_{x^3}^{x^2} dy \right] dx = \int_0^1 [y]_{x^3}^{x^2} dx \\ &= \int_0^1 (x^2 - x^3) dx = \left[\frac{x^3}{3} - \frac{x^4}{4} \right]_0^1 = \left(\frac{1}{3} - \frac{1}{4} \right) - 0 = \boxed{\frac{1}{12} \text{ square units}}. \end{aligned}$$

30. We begin by graphing the region R enclosed by the graphs of $y = 2\sqrt{x}$ and $y = \frac{x^2}{4}$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = \frac{x^2}{4}$ to $y = 2\sqrt{x}$, $0 \leq x \leq 4$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_0^4 \left[\int_{x^2/4}^{2\sqrt{x}} dy \right] dx = \int_0^4 [y]_{x^2/4}^{2\sqrt{x}} dx \\ &= \int_0^4 \left(2\sqrt{x} - \frac{x^2}{4} \right) dx = \int_0^4 \left(2x^{1/2} - \frac{1}{4}x^2 \right) dx = \left[2 \cdot \frac{x^{3/2}}{3/2} - \frac{1}{4} \cdot \frac{x^3}{3} \right]_0^4 \\ &= \left[\frac{4}{3} (\sqrt{x})^3 - \frac{1}{12} x^3 \right]_0^4 = \left(\frac{4}{3} \cdot (\sqrt{4})^3 - \frac{1}{12} \cdot 4^3 \right) - 0 = \frac{32}{3} - \frac{16}{3} = \boxed{\frac{16}{3} \text{ square units}}. \end{aligned}$$

31. We begin by graphing the region R enclosed by the graphs of $y = x^2 - 9$ and $y = 9 - x^2$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = x^2 - 9$ to

$y = 9 - x^2$, $-3 \leq x \leq 3$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_{-3}^3 \left[\int_{x^2-9}^{9-x^2} dy \right] dx = \int_{-3}^3 [y]_{x^2-9}^{9-x^2} dx = \int_{-3}^3 [(9-x^2) - (x^2-9)] dx \\ &= \int_{-3}^3 (18-2x^2) dx = \left[18x - \frac{2x^3}{3} \right]_{-3}^3 = (54-18) - (-54+18) = \boxed{72 \text{ square units}}. \end{aligned}$$

32. We begin by graphing the region R enclosed by the graphs of $x = \sqrt{16-y^2}$ and $y^2 = 6x$; see the figure below. Observe that R is a closed bounded region, that is y -simple: x varies from $x = \frac{y^2}{6}$ to $x = \sqrt{16-y^2}$, $-2\sqrt{3} \leq y \leq 2\sqrt{3}$. Also note that the region R is symmetric about the x -axis, so we can find the area of its half lying in the first quadrant, that is for $0 \leq y \leq 2\sqrt{3}$, and multiply it by 2. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = 2 \int_0^{2\sqrt{3}} \left[\int_{y^2/6}^{\sqrt{16-y^2}} dx \right] dy = 2 \int_0^{2\sqrt{3}} [x]_{y^2/6}^{\sqrt{16-y^2}} dy \\ &= 2 \int_0^{2\sqrt{3}} \left(\sqrt{16-y^2} - \frac{y^2}{6} \right) dy = 2 \int_0^{2\sqrt{3}} \sqrt{16-y^2} dy - \frac{1}{3} \int_0^{2\sqrt{3}} y^2 dy. \end{aligned}$$

The second integral can be evaluated directly as

$$\frac{1}{3} \int_0^{2\sqrt{3}} y^2 dy = \frac{1}{3} \left[\frac{y^3}{3} \right]_0^{2\sqrt{3}} = \frac{1}{9} [y^3]_0^{2\sqrt{3}} = \frac{1}{9} \left((2\sqrt{3})^3 - 0^3 \right) = \frac{1}{9} \cdot 24\sqrt{3} = \frac{8\sqrt{3}}{3}.$$

To find the first integral, we will find an antiderivative using a substitution $y = 4 \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dy = 4 \cos \theta d\theta$. Also,

$$\sqrt{16-y^2} = \sqrt{16-16\sin^2\theta} = \sqrt{16(1-\sin^2\theta)} = \sqrt{16\cos^2\theta} = 4\cos\theta,$$

and the integral becomes

$$\begin{aligned} 2 \int \sqrt{16-y^2} dy &= 2 \int 4\cos\theta \cdot 4\cos\theta d\theta = 32 \int \cos^2\theta d\theta = 32 \int \frac{1}{2}(1+\cos 2\theta) d\theta \\ &= 16 \int (1+\cos 2\theta) d\theta = 16 \left(\theta + \frac{1}{2} \sin 2\theta \right) = 16(\theta + \sin\theta \cos\theta). \end{aligned}$$

To express this antiderivative in terms of y , we first observe that since $y = 4 \sin \theta$, then $\sin \theta = \frac{y}{4}$ and

$\theta = \sin^{-1}\left(\frac{y}{4}\right)$; also, since $\sqrt{16-y^2} = 4\cos\theta$ (as shown above), then $\cos\theta = \frac{\sqrt{16-y^2}}{4}$. So,

$$16(\theta + \sin\theta\cos\theta) = 16\left(\sin^{-1}\left(\frac{y}{4}\right) + \frac{y}{4} \cdot \frac{\sqrt{16-y^2}}{4}\right) = 16\sin^{-1}\left(\frac{y}{4}\right) + y\sqrt{16-y^2}$$

is an antiderivative, and

$$\begin{aligned} 2 \int_0^{2\sqrt{3}} \sqrt{16-y^2} dy &= \left[16\sin^{-1}\left(\frac{y}{4}\right) + y\sqrt{16-y^2} \right]_0^{2\sqrt{3}} \\ &= \left(16\sin^{-1}\left(\frac{\sqrt{3}}{2}\right) + 2\sqrt{3} \cdot \sqrt{16-12} \right) - \left(16\sin^{-1}(0) + 0 \cdot \sqrt{16} \right) \\ &= 16 \cdot \frac{\pi}{3} + 2\sqrt{3} \cdot 2 - 0 = \frac{16\pi}{3} + 4\sqrt{3}. \end{aligned}$$

So the final answer is

$$A = \frac{16\pi}{3} + 4\sqrt{3} - \frac{8\sqrt{3}}{3} = \frac{16\pi}{3} - \frac{4\sqrt{3}}{3} = \boxed{\frac{16\pi - 4\sqrt{3}}{3} \text{ square units}}.$$

33. We begin by graphing the region R enclosed by the graph $y = \frac{1}{\sqrt{x-1}}$, the x -axis, and the lines $x = 2$ and $x = 5$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = 0$ to $y = \frac{1}{\sqrt{x-1}}$, $2 \leq x \leq 5$. Then the area A of the region R is

$$A = \iint_R dA = \int_2^5 \left[\int_0^{1/\sqrt{x-1}} dy \right] dx = \int_2^5 [y]_0^{1/\sqrt{x-1}} dx = \int_2^5 \frac{1}{\sqrt{x-1}} dx.$$

To evaluate this integral, we make a substitution $u = x - 1$; then $du = dx$. We also change the limits of integration: if $x = 2$, then $u = 2 - 1 = 1$; if $x = 5$, then $u = 5 - 1 = 4$. So

$$\begin{aligned} A &= \int_2^5 \frac{1}{\sqrt{x-1}} dx = \int_1^4 \frac{1}{\sqrt{u}} du = \int_1^4 u^{-1/2} du \\ &= \left[\frac{u^{1/2}}{1/2} \right]_1^4 = [2\sqrt{u}]_1^4 = 2\sqrt{4} - 2\sqrt{1} = 4 - 2 = \boxed{2 \text{ square units}}. \end{aligned}$$

34. We begin by graphing the region R enclosed by the graphs of $y = x^{3/2}$ and $y = x$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = x^{3/2}$ to $y = x$, $0 \leq x \leq 1$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_0^1 \left[\int_{x^{3/2}}^x dy \right] dx = \int_0^1 [y]_{x^{3/2}}^x dx = \int_0^1 (x - x^{3/2}) dx \\ &= \left[\frac{x^2}{2} - \frac{x^{5/2}}{5/2} \right]_0^1 = \left[\frac{1}{2}x^2 - \frac{2}{5}x^{5/2} \right]_0^1 = \left(\frac{1}{2} - \frac{2}{5} \right) - 0 = \boxed{\frac{1}{10} \text{ square units}}. \end{aligned}$$

35. We begin by graphing the region R enclosed by the line $x + y = 3$ and the hyperbola $xy = 2$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = \frac{2}{x}$ to $y = 3 - x$, $1 \leq x \leq 2$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_1^2 \left[\int_{2/x}^{3-x} dy \right] dx = \int_1^2 [y]_{2/x}^{3-x} dx = \int_1^2 \left(3 - x - \frac{2}{x} \right) dx \\ &= \left[3x - \frac{x^2}{2} - 2 \ln x \right]_1^2 = (6 - 2 - 2 \ln 2) - \left(3 - \frac{1}{2} - 2 \ln 1 \right) = \boxed{\frac{3}{2} - 2 \ln 2 \text{ square units}}. \end{aligned}$$

36. We begin by graphing the region R enclosed by the hyperbola $xy = \sqrt{3}$ and the circle $x^2 + y^2 = 4$ in the first quadrant; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = \frac{\sqrt{3}}{x}$ to $y = \sqrt{4 - x^2}$, $1 \leq x \leq \sqrt{3}$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_1^{\sqrt{3}} \left[\int_{\sqrt{3}/x}^{\sqrt{4-x^2}} dy \right] dx = \int_1^{\sqrt{3}} [y]_{\sqrt{3}/x}^{\sqrt{4-x^2}} dx \\ &= \int_1^{\sqrt{3}} \left(\sqrt{4-x^2} - \frac{\sqrt{3}}{x} \right) dx = \int_1^{\sqrt{3}} \sqrt{4-x^2} dx - \int_1^{\sqrt{3}} \frac{\sqrt{3}}{x} dx. \end{aligned}$$

The second integral can be evaluated directly as

$$\int_1^{\sqrt{3}} \frac{\sqrt{3}}{x} dx = \sqrt{3} [\ln x]_1^{\sqrt{3}} = \sqrt{3} (\ln \sqrt{3} - \ln 1) = \sqrt{3} \left(\frac{1}{2} \ln 3 - 0 \right) = \frac{\sqrt{3} \ln 3}{2}.$$

To find the first integral, we will find an antiderivative using a substitution $x = 2 \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = 2 \cos \theta d\theta$. Also,

$$\sqrt{4-x^2} = \sqrt{4-4\sin^2 \theta} = \sqrt{4(1-\sin^2 \theta)} = \sqrt{4\cos^2 \theta} = 2 \cos \theta,$$

and the integral becomes

$$\begin{aligned} \int \sqrt{4-x^2} dx &= \int 2 \cos \theta \cdot 2 \cos \theta d\theta = 4 \int \cos^2 \theta d\theta = 4 \int \frac{1}{2} (1 + \cos 2\theta) d\theta \\ &= 2 \int (1 + \cos 2\theta) d\theta = 2 \left(\theta + \frac{1}{2} \sin 2\theta \right) = 2(\theta + \sin \theta \cos \theta). \end{aligned}$$

To express this antiderivative in terms of x , we first observe that since $x = 2 \sin \theta$, then $\sin \theta = \frac{x}{2}$ and $\theta = \sin^{-1} \left(\frac{x}{2} \right)$; also, since $\sqrt{4-x^2} = 2 \cos \theta$ (as shown above), then $\cos \theta = \frac{\sqrt{4-x^2}}{2}$. So,

$$2(\theta + \sin \theta \cos \theta) = 2 \left(\sin^{-1} \left(\frac{x}{2} \right) + \frac{x}{2} \cdot \frac{\sqrt{4-x^2}}{2} \right) = 2 \sin^{-1} \left(\frac{x}{2} \right) + \frac{x\sqrt{4-x^2}}{2}$$

is an antiderivative, and

$$\begin{aligned} \int_1^{\sqrt{3}} \sqrt{4-x^2} dx &= \left[2 \sin^{-1} \left(\frac{x}{2} \right) + \frac{x\sqrt{4-x^2}}{2} \right]_1^{\sqrt{3}} \\ &= \left(2 \sin^{-1} \left(\frac{\sqrt{3}}{2} \right) + \frac{\sqrt{3} \cdot \sqrt{4-3}}{2} \right) - \left(2 \sin^{-1} \left(\frac{1}{2} \right) + \frac{1 \cdot \sqrt{4-1}}{2} \right) \\ &= \left(2 \cdot \frac{\pi}{3} + \frac{\sqrt{3}}{2} \right) - \left(2 \cdot \frac{\pi}{6} + \frac{\sqrt{3}}{2} \right) = \frac{2\pi}{3} + \frac{\sqrt{3}}{2} - \frac{\pi}{3} - \frac{\sqrt{3}}{2} = \frac{\pi}{3}. \end{aligned}$$

So the final answer is $A = \boxed{\frac{\pi}{3} - \frac{\sqrt{3} \ln 3}{2} \text{ square units}}.$

37. We begin by graphing the region R associated with the integral $\int_0^1 \left[\int_0^x f(x, y) dy \right] dx$: it is the region between the graphs of $y = 0$ and $y = x$, where $0 \leq x \leq 1$; see the figure. Observe that R is also a y -simple region: x varies from $x = y$ to $x = 1$, where $0 \leq y \leq 1$. Then according to Fubini's Theorem,

$$\int_0^1 \left[\int_0^x f(x, y) dy \right] dx = \iint_R f(x, y) dA = \boxed{\int_0^1 \left[\int_y^1 f(x, y) dx \right] dy}.$$

38. We begin by graphing the region R associated with the integral $\int_0^2 \left[\int_{y^2}^{2y} f(x, y) dx \right] dy$: it is the region between the graphs of $x = y^2$ and $x = 2y$, where $0 \leq y \leq 2$; see the figure. Observe that R is also an x -simple region: y varies from $y = \frac{x}{2}$ to $y = \sqrt{x}$, where $0 \leq x \leq 4$. Then according to Fubini's Theorem,

$$\int_0^2 \left[\int_{y^2}^{2y} f(x, y) dx \right] dy = \iint_R f(x, y) dA = \boxed{\int_0^4 \left[\int_{x/2}^{\sqrt{x}} f(x, y) dy \right] dx}.$$

39. We begin by graphing the region R associated with the integral $\int_0^a \left[\int_0^{\sqrt{a^2-y^2}} f(x, y) dx \right] dy$: it is the region between the graphs of $x = 0$ and $x = \sqrt{a^2 - y^2}$, where $0 \leq y \leq a$; see the figure. As we can see, R is the quarter of the disk bounded by the circle $x^2 + y^2 = a^2$ in the first quadrant. Observe that R is also an x -simple region: y varies from $y = 0$ to $y = \sqrt{a^2 - x^2}$, where $0 \leq x \leq a$. Then according to Fubini's Theorem,

$$\int_0^a \left[\int_0^{\sqrt{a^2-y^2}} f(x, y) dx \right] dy = \iint_R f(x, y) dA = \boxed{\int_0^a \left[\int_0^{\sqrt{a^2-x^2}} f(x, y) dy \right] dx}.$$

40. We begin by graphing the region R associated with the integral $\int_0^{2\sqrt[3]{2}} \left[\int_{x^2/4}^{\sqrt{x}} f(x, y) dy \right] dx$: it is the region between the graphs of $y = \frac{x^2}{4}$ and $y = \sqrt{x}$, where $0 \leq x \leq 2\sqrt[3]{2}$; see the figure. Observe that R is also a y -simple region: x varies from $x = y^2$ to $x = 2\sqrt{y}$, where $0 \leq y \leq \sqrt[3]{4}$. Then according to Fubini's Theorem,

$$\int_0^{2\sqrt[3]{2}} \left[\int_{x^2/4}^{\sqrt{x}} f(x, y) dy \right] dx = \iint_R f(x, y) dA = \boxed{\int_0^{\sqrt[3]{4}} \left[\int_{y^2}^{2\sqrt{y}} f(x, y) dx \right] dy}.$$

41. We begin by graphing the region R associated with the integral $\int_0^{16} \left[\int_{y/8}^{y^{1/4}} f(x, y) dx \right] dy$: it is the region between the graphs of $x = \frac{y}{8}$ and $x = y^{1/4}$, where $0 \leq y \leq 16$; see the figure. Observe that R is also an x -simple region: y varies from $y = x^4$ to $y = 8x$, where $0 \leq x \leq 2$. Then according to Fubini's Theorem,

$$\int_0^{16} \left[\int_{y/8}^{y^{1/4}} f(x, y) dx \right] dy = \iint_R f(x, y) dA = \boxed{\int_0^2 \left[\int_{x^4}^{8x} f(x, y) dy \right] dx}.$$

42. We begin by graphing the region R associated with the integral $\int_2^5 \left[\int_{x^2-6x+9}^{x-1} f(x, y) dy \right] dx$: it is the region between the graphs of $y = x^2 - 6x + 9$ and $y = x - 1$, where $2 \leq x \leq 5$; see figure (a). Notice that R is not a y -simple region because of the corner at $(2, 1)$. But the horizontal line through $(2, 1)$ partitions R into two subregions R_1 and R_2 , shown in figure (b), both of which are y -simple. We can solve the equation of the parabola for x : $y = x^2 - 6x + 9 = (x - 3)^2$, so $x - 3 = \pm\sqrt{y}$ and $x = 3 \pm \sqrt{y}$. So R_1 is enclosed between $x = 3 - \sqrt{y}$ and $x = 3 + \sqrt{y}$, where $0 \leq y \leq 1$; and R_2 is enclosed between $x = y + 1$ and $x = 3 + \sqrt{y}$, where $1 \leq y \leq 4$. Then according to Fubini's Theorem,

$$\begin{aligned} \int_2^5 \left[\int_{x^2-6x+9}^{x-1} f(x, y) dy \right] dx &= \iint_R f(x, y) dA = \iint_{R_1} f(x, y) dA + \iint_{R_2} f(x, y) dA \\ &= \int_0^1 \left[\int_{3-\sqrt{y}}^{3+\sqrt{y}} f(x, y) dx \right] dy + \int_1^4 \left[\int_{y+1}^{3+\sqrt{y}} f(x, y) dx \right] dy. \end{aligned}$$

43. We begin by graphing the region R associated with the integral $\int_1^2 \left[\int_0^{\ln y} f(x, y) dx \right] dy$: it is the region between the graphs of $x = 0$ and $x = \ln y$, where $1 \leq y \leq 2$; see the figure. Observe that R is also an x -simple region: y varies from $y = e^x$ to $y = 2$, where $0 \leq x \leq \ln 2$. Then according to Fubini's Theorem,

$$\int_1^2 \left[\int_0^{\ln y} f(x, y) dx \right] dy = \iint_R f(x, y) dA = \int_0^{\ln 2} \left[\int_{e^x}^2 f(x, y) dy \right] dx.$$

44. We begin by graphing the region R associated with the integral $\int_1^e \left[\int_{\ln x}^1 f(x, y) dy \right] dx$: it is the region between the graphs of $y = \ln x$ and $y = 1$, where $1 \leq x \leq e$; see the figure. Observe that R is also an x -simple region: x varies from $x = 1$ to $x = e^y$, where $0 \leq y \leq 1$. Then according to Fubini's Theorem,

$$\int_1^e \left[\int_{\ln x}^1 f(x, y) dy \right] dx = \iint_R f(x, y) dA = \boxed{\int_0^1 \left[\int_1^{e^y} f(x, y) dx \right] dy}.$$

45. Using properties of double integrals,

$$\iint_R [f(x, y) - g(x, y)] dA = \iint_R f(x, y) dA - \iint_R g(x, y) dA = 8 - (-6) = \boxed{14}.$$

46. Using properties of double integrals,

$$\iint_R 4f(x, y) dA = 4 \iint_R f(x, y) dA = 4 \cdot 8 = \boxed{32}.$$

47. Using properties of double integrals,

$$\begin{aligned} \iint_R [3f(x, y) + 4g(x, y)] dA &= \iint_R 3f(x, y) dA + \iint_R 4g(x, y) dA \\ &= 3 \iint_R f(x, y) dA + 4 \iint_R g(x, y) dA = 3 \cdot 8 + 4 \cdot (-6) = \boxed{0}. \end{aligned}$$

48. Using properties of double integrals,

$$\begin{aligned} \iint_R [2f(x, y) + 5g(x, y)] dA &= \iint_R 2f(x, y) dA + \iint_R 5g(x, y) dA \\ &= 2 \iint_R f(x, y) dA + 5 \iint_R g(x, y) dA = 2 \cdot 8 + 5 \cdot (-6) = \boxed{-14}. \end{aligned}$$

Applications and Extensions

49. We begin by graphing the region R enclosed by the graphs of $y = 6x - x^2$ and $y = 4x - 8$; it is shown in Figure 20. Notice that R is not a y -simple region because of the corner at $(4, 8)$. But the horizontal line through $(4, 8)$ partitions R into two subregions R_1 and R_2 , both of which are y -simple; see the figure below. We can solve the equation of the parabola for x :

$$y = 6x - x^2, \text{ so } -y = x^2 - 6x, \text{ so } 9 - y = x^2 - 6x + 9 = (x - 3)^2, \text{ so } x - 3 = \pm\sqrt{9 - y}, \text{ so } x = 3 \pm \sqrt{9 - y}.$$

So R_1 is enclosed between $x = 3 - \sqrt{9 - y}$ and $x = 2 + \frac{y}{4}$, where $0 \leq y \leq 8$; and R_2 is enclosed between $x = 3 - \sqrt{9 - y}$ and $x = 3 + \sqrt{9 - y}$, where $8 \leq y \leq 9$. Then according to Fubini's Theorem, the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \iint_{R_1} dA + \iint_{R_2} dA \\ &= \int_0^8 \left[\int_{3-\sqrt{9-y}}^{2+y/4} dx \right] dy + \int_8^9 \left[\int_{3-\sqrt{9-y}}^{3+\sqrt{9-y}} dx \right] dy = \int_0^8 [x]_{3-\sqrt{9-y}}^{2+y/4} dy + \int_8^9 [x]_{3-\sqrt{9-y}}^{3+\sqrt{9-y}} dy \\ &= \int_0^8 \left[\left(2 + \frac{y}{4} \right) - \left(3 - \sqrt{9-y} \right) \right] dy + \int_8^9 \left[\left(3 + \sqrt{9-y} \right) - \left(3 - \sqrt{9-y} \right) \right] dy \\ &= \int_0^8 \left(-1 + \frac{y}{4} + \sqrt{9-y} \right) dy + \int_8^9 2\sqrt{9-y} dy \\ &= \int_0^8 \left(-1 + \frac{y}{4} \right) dy + \int_0^8 \sqrt{9-y} dy + \int_8^9 2\sqrt{9-y} dy. \end{aligned}$$

The first integral $\int_0^8 \left(-1 + \frac{y}{4} \right) dy$ can be evaluated directly as

$$\int_0^8 \left(-1 + \frac{y}{4} \right) dy = \left[-y + \frac{y^2}{8} \right]_0^8 = (-8 + 8) - (-0 + 0) = 0.$$

To evaluate the second integral $\int_0^8 \sqrt{9-y} dy$, we make a substitution $u = 9 - y$; then $du = -dy$, so $dy = -du$. We also change the limits of integration: if $y = 0$, then $u = 9 - 0 = 9$; if $y = 8$, then $u = 9 - 8 = 1$. So

$$\begin{aligned} \int_0^8 \sqrt{9-y} dy &= \int_9^1 \sqrt{u} (-du) = - \int_9^1 \sqrt{u} du = \int_1^9 u^{1/2} du \\ &= \left[\frac{u^{3/2}}{3/2} \right]_1^9 = \left[\frac{2}{3} (\sqrt{u})^3 \right]_1^9 = \frac{2}{3} \left((\sqrt{9})^3 - (\sqrt{1})^3 \right) = \frac{2}{3} (27 - 1) = \frac{52}{3}. \end{aligned}$$

Similarly, we apply the same substitution $u = 9 - y$, $du = -dy$ to evaluate the third integral $\int_8^9 2\sqrt{9-y} dy$. The new limits of integration will be: if $y = 8$, then $u = 9 - 8 = 1$; if $y = 9$,

then $u = 9 - 9 = 0$. So

$$\begin{aligned}\int_8^9 2\sqrt{9-y} dy &= \int_1^0 2\sqrt{u} (-du) = -\int_1^0 2\sqrt{u} du \\ &= \int_0^1 2u^{1/2} du = \left[2 \cdot \frac{u^{3/2}}{3/2} \right]_0^1 = \left[\frac{4}{3} u^{3/2} \right]_0^1 = \frac{4}{3}(1-0) = \frac{4}{3}.\end{aligned}$$

The final answer is

$$A = \int_0^8 \left(-1 + \frac{y}{4}\right) dy + \int_0^8 \sqrt{9-y} dy + \int_8^9 2\sqrt{9-y} dy = 0 + \frac{52}{3} + \frac{4}{3} = \boxed{\frac{56}{3} \text{ square units}}.$$

50. We begin by graphing the region R enclosed by the y -axis, the circle $x^2 + y^2 = 10$, and the parabola $x^2 = 9y$ in the first quadrant; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = \frac{x^2}{9}$ to $y = \sqrt{10-x^2}$, $0 \leq x \leq 3$. So the area A of the region R is

$$\begin{aligned}A &= \iint_R dA = \int_0^3 \left[\int_{x^2/9}^{\sqrt{10-x^2}} dy \right] dx = \int_0^3 [y]_{x^2/9}^{\sqrt{10-x^2}} dx \\ &= \int_0^3 \left(\sqrt{10-x^2} - \frac{x^2}{9} \right) dx = \int_0^3 \sqrt{10-x^2} dx - \frac{1}{9} \int_0^3 x^2 dx.\end{aligned}$$

The second integral can be evaluated directly as

$$\frac{1}{9} \int_0^3 x^2 dx = \frac{1}{9} \left[\frac{x^3}{3} \right]_0^3 = \frac{1}{27} [x^3]_0^3 = \frac{1}{27} (3^3 - 0^3) = \frac{1}{27} \cdot 27 = 1.$$

To find the first integral, we will find an antiderivative using a substitution $x = \sqrt{10} \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = \sqrt{10} \cos \theta d\theta$. Also,

$$\sqrt{10-x^2} = \sqrt{10-10\sin^2 \theta} = \sqrt{10(1-\sin^2 \theta)} = \sqrt{10\cos^2 \theta} = \sqrt{10} \cos \theta,$$

and the integral becomes

$$\begin{aligned}\int \sqrt{10-x^2} dx &= \int \sqrt{10} \cos \theta \cdot \sqrt{10} \cos \theta d\theta = 10 \int \cos^2 \theta d\theta = 10 \int \frac{1}{2} (1 + \cos 2\theta) d\theta \\ &= 5 \int (1 + \cos 2\theta) d\theta = 5 \left(\theta + \frac{1}{2} \sin 2\theta \right) = 5 (\theta + \sin \theta \cos \theta).\end{aligned}$$

To express this antiderivative in terms of x , we observe that since $x = \sqrt{10} \sin \theta$, then $\sin \theta = \frac{x}{\sqrt{10}}$ and $\theta = \sin^{-1} \left(\frac{x}{\sqrt{10}} \right)$; also, since $\sqrt{10-x^2} = \sqrt{10} \cos \theta$ (as shown above), then $\cos \theta = \frac{\sqrt{10-x^2}}{\sqrt{10}}$. So,

$$5 (\theta + \sin \theta \cos \theta) = 5 \left(\sin^{-1} \left(\frac{x}{\sqrt{10}} \right) + \frac{x}{\sqrt{10}} \cdot \frac{\sqrt{10-x^2}}{\sqrt{10}} \right) = 5 \sin^{-1} \left(\frac{x}{\sqrt{10}} \right) + \frac{1}{2} x \sqrt{10-x^2}$$

is an antiderivative, and

$$\begin{aligned}\int_0^3 \sqrt{10-x^2} dx &= \left[5 \sin^{-1} \left(\frac{x}{\sqrt{10}} \right) + \frac{1}{2} x \sqrt{10-x^2} \right]_0^3 \\ &= \left(5 \sin^{-1} \left(\frac{3}{\sqrt{10}} \right) + \frac{1}{2} \cdot 3 \cdot \sqrt{10-9} \right) - \left(5 \sin^{-1}(0) + \frac{1}{2} \cdot 0 \cdot \sqrt{10-0} \right) \\ &= 5 \sin^{-1} \left(\frac{3}{\sqrt{10}} \right) + \frac{3}{2} - 0 = 5 \sin^{-1} \left(\frac{3}{\sqrt{10}} \right) + \frac{3}{2}.\end{aligned}$$

So the final answer is

$$A = 5 \sin^{-1} \left(\frac{3}{\sqrt{10}} \right) + \frac{3}{2} - 1 = \boxed{5 \sin^{-1} \left(\frac{3}{\sqrt{10}} \right) + \frac{1}{2} \text{ square units}}.$$

51. We begin by graphing the solid S enclosed by the plane $x + 2y + z = 2$ and the coordinate planes. This solid lies in the first octant under the graph of $z = f(x, y) = 2 - x - 2y$ and above the region R in the xy -plane bounded by the coordinate axes and the line $x + 2y = 2$. Observe that R is a y -simple region: x varies from $x = 0$ to $x = 2 - 2y$, $0 \leq y \leq 1$; see the figures below. So the volume V of the solid S is

$$\begin{aligned} V &= \iint_R f(x, y) dA = \int_0^1 \left[\int_0^{2-2y} (2 - x - 2y) dx \right] dy = \int_0^1 \left[2x - \frac{x^2}{2} - 2yx \right]_0^{2-2y} dy \\ &= \int_0^1 \left[\left(2(2 - 2y) - \frac{(2 - 2y)^2}{2} - 2y(2 - 2y) \right) - 0 \right] dy \\ &= \int_0^1 [(4 - 4y) - (2 - 4y + 2y^2) - (4y - 4y^2)] dy \\ &= \int_0^1 (2y^2 - 4y + 2) dy = \left[\frac{2y^3}{3} - 2y^2 + 2y \right]_0^1 = \left(\frac{2}{3} - 2 + 2 \right) - 0 = \boxed{\frac{2}{3} \text{ cubic units}}. \end{aligned}$$

52. We begin by graphing the solid S enclosed by the elliptic cylinder $4x^2 + 9y^2 = 36$ and the planes $z = 0$ and $z = 1$. This solid lies under the graph of $z = f(x, y) = 1$ and above the region R in the xy -plane bounded by the ellipse $4x^2 + 9y^2 = 36$; see the figures below. Notice that the solid S is symmetric, consisting of four equal parts over each quadrant. So we can find its volume by integrating over the part of the region R lying in the first quadrant and then multiplying it by four. Observe that the first-quadrant part of R is an x -simple region: y varies from $y = 0$ to $y = \sqrt{4 - \frac{4}{9}x^2} = 2\sqrt{1 - \frac{x^2}{9}}$,

where $0 \leq x \leq 3$. So the volume V of the solid S is

$$\begin{aligned} V &= \iint_R f(x, y) dA = 4 \int_0^3 \left[\int_0^{2\sqrt{1-x^2/9}} 1 dy \right] dx \\ &= 4 \int_0^3 [y]_0^{2\sqrt{1-x^2/9}} dx = 4 \int_0^3 \left[2\sqrt{1 - \frac{x^2}{9}} - 0 \right] dx = 8 \int_0^3 \sqrt{1 - \frac{x^2}{9}} dx. \end{aligned}$$

To evaluate this integral, we will find an antiderivative using a substitution $x = 3 \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = 3 \cos \theta d\theta$. Also,

$$\sqrt{1 - \frac{x^2}{9}} = \sqrt{1 - \frac{9 \sin^2 \theta}{9}} = \sqrt{1 - \sin^2 \theta} = \sqrt{\cos^2 \theta} = \cos \theta,$$

and the integral becomes

$$\begin{aligned} 8 \int \sqrt{1 - \frac{x^2}{9}} dx &= 8 \int \cos \theta \cdot 3 \cos \theta d\theta = 24 \int \cos^2 \theta d\theta = 24 \int \frac{1}{2} (1 + \cos 2\theta) d\theta \\ &= 12 \int (1 + \cos 2\theta) d\theta = 12 \left(\theta + \frac{1}{2} \sin 2\theta \right) = 12 (\theta + \sin \theta \cos \theta). \end{aligned}$$

To express this antiderivative in terms of x , we first observe that since $x = 3 \sin \theta$, then $\sin \theta = \frac{x}{3}$ and $\theta = \sin^{-1} \left(\frac{x}{3} \right)$; also, as shown above, $\cos \theta = \sqrt{1 - \frac{x^2}{9}} = \frac{\sqrt{9 - x^2}}{3}$. So,

$$12 (\theta + \sin \theta \cos \theta) = 12 \left(\sin^{-1} \left(\frac{x}{3} \right) + \frac{x}{3} \cdot \frac{\sqrt{9 - x^2}}{3} \right) = 12 \sin^{-1} \left(\frac{x}{3} \right) + \frac{4}{3} x \sqrt{9 - x^2}$$

is an antiderivative, and

$$\begin{aligned} V &= 8 \int_0^3 \sqrt{1 - \frac{x^2}{9}} dx = \left[12 \sin^{-1} \left(\frac{x}{3} \right) + \frac{4}{3} x \sqrt{9 - x^2} \right]_0^3 \\ &= \left(12 \sin^{-1}(1) + \frac{4}{3} \cdot 3 \cdot \sqrt{9 - 9} \right) - \left(12 \sin^{-1}(0) + \frac{4}{3} \cdot 0 \cdot \sqrt{9 - 0} \right) \\ &= \left(12 \cdot \frac{\pi}{2} + 0 \right) - 0 = \boxed{6\pi \text{ cubic units}}. \end{aligned}$$

53. We begin by graphing the solid S that lies below the circular paraboloid $z = f(x, y) = x^2 + y^2$ and the triangular region R in the xy -plane as shown in the figure in Problem 53. Observe that R is an

x -simple region: y varies from $y = 0$ to $y = 1 - x$, where $0 \leq x \leq 1$; see the figure below. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) \, dA = \int_0^1 \left[\int_0^{1-x} (x^2 + y^2) \, dy \right] dx = \int_0^1 \left[x^2 y + \frac{y^3}{3} \right]_0^{1-x} dx \\
 &= \int_0^1 \left[\left(x^2(1-x) + \frac{(1-x)^3}{3} \right) - 0 \right] dx = \int_0^1 \left(x^2 - x^3 + \frac{1-3x+3x^2-x^3}{3} \right) dx \\
 &= \int_0^1 \left(-\frac{4}{3}x^3 + 2x^2 - x + \frac{1}{3} \right) dx = \left[-\frac{1}{3}x^4 + \frac{2}{3}x^3 - \frac{1}{2}x^2 + \frac{1}{3}x \right]_0^1 \\
 &= \left(-\frac{1}{3} + \frac{2}{3} - \frac{1}{2} + \frac{1}{3} \right) - 0 = \boxed{\frac{1}{6} \text{ cubic units}}.
 \end{aligned}$$

54. We begin by graphing the solid S enclosed by the parabolic cylinder $z = 9 - y^2$ and the planes $z = 0$, $x = 0$, and $x = 4$. This solid lies under the graph of $z = f(x, y) = 9 - y^2$ and above the region R in the xy -plane, which is a rectangle $0 \leq x \leq 4$, $-3 \leq y \leq 3$; see the figures below. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) \, dA = \int_0^4 \left[\int_{-3}^3 (9 - y^2) \, dy \right] dx = \int_0^4 \left[9y - \frac{y^3}{3} \right]_{-3}^3 dx \\
 &= \int_0^4 [(27 - 9) - (-27 + 9)] dx = \int_0^4 36 \, dx = [36x]_0^4 = 36 \cdot 4 - 36 \cdot 0 = \boxed{144 \text{ cubic units}}.
 \end{aligned}$$

55. We begin by graphing the solid S enclosed by the circular paraboloid $z = 4 - x^2 - y^2$ and the plane $z = 0$. This solid lies under the graph of $z = f(x, y) = 4 - x^2 - y^2$ and above the region R in the xy -plane, that is the disk $x^2 + y^2 \leq 4$; see the figures below. Notice that the solid S is symmetric, consisting of four equal parts over each quadrant. So we can find its volume by integrating over the part of the region R lying in the first quadrant and then multiplying it by four. Observe that the

first-quadrant part of R is an x -simple region: y varies from $y = 0$ to $y = \sqrt{4 - x^2}$, where $0 \leq x \leq 2$. So the volume V of the solid S is

$$\begin{aligned} V &= \iint_R f(x, y) dA = 4 \int_0^2 \left[\int_0^{\sqrt{4-x^2}} (4 - x^2 - y^2) dy \right] dx = 4 \int_0^2 \left[4y - x^2y - \frac{y^3}{3} \right]_0^{\sqrt{4-x^2}} dx \\ &= 4 \int_0^2 \left[\left(4\sqrt{4-x^2} - x^2\sqrt{4-x^2} - \frac{(\sqrt{4-x^2})^3}{3} \right) - 0 \right] dx \\ &= 4 \int_0^2 \left[(4 - x^2)\sqrt{4-x^2} - \frac{(\sqrt{4-x^2})^3}{3} \right] dx = 4 \int_0^2 \left[(\sqrt{4-x^2})^3 - \frac{(\sqrt{4-x^2})^3}{3} \right] dx \\ &= 4 \int_0^2 \frac{2}{3} (\sqrt{4-x^2})^3 dx = \frac{8}{3} \int_0^2 (\sqrt{4-x^2})^3 dx. \end{aligned}$$

To evaluate this integral, we will find an antiderivative using a substitution $x = 2 \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = 2 \cos \theta d\theta$. Also,

$$\sqrt{4-x^2} = \sqrt{4-4\sin^2\theta} = \sqrt{4(1-\sin^2\theta)} = \sqrt{4\cos^2\theta} = 2\cos\theta,$$

and the integral becomes

$$\begin{aligned} \frac{8}{3} \int (\sqrt{4-x^2})^3 dx &= \frac{8}{3} \int (2\cos\theta)^3 \cdot 2\cos\theta d\theta = \frac{128}{3} \int \cos^4\theta d\theta = \frac{128}{3} \int (\cos^2\theta)^2 d\theta \\ &= \frac{128}{3} \int \left(\frac{1}{2}(1 + \cos 2\theta) \right)^2 d\theta = \frac{128}{3} \int \frac{1}{4}(1 + 2\cos 2\theta + \cos^2 2\theta) d\theta \\ &= \frac{32}{3} \int \left(1 + 2\cos 2\theta + \frac{1}{2}(1 + \cos 4\theta) \right) d\theta = \frac{32}{3} \int \left(\frac{3}{2} + 2\cos 2\theta + \frac{1}{2}\cos 4\theta \right) d\theta \\ &= \int \left(16 + \frac{64}{3}\cos 2\theta + \frac{16}{3}\cos 4\theta \right) d\theta = 16\theta + \frac{64}{3} \cdot \frac{1}{2}\sin 2\theta + \frac{16}{3} \cdot \frac{1}{4}\sin 4\theta \\ &= 16\theta + \frac{32}{3}\sin 2\theta + \frac{4}{3}\sin 4\theta. \end{aligned}$$

To express this antiderivative in terms of x , we first observe that since $x = 2 \sin \theta$, then $\sin \theta = \frac{x}{2}$ and $\theta = \sin^{-1}\left(\frac{x}{2}\right)$; also, as shown above, $\sqrt{4-x^2} = 2\cos\theta$, so $\cos\theta = \frac{\sqrt{4-x^2}}{2}$. Then

$$\sin 2\theta = 2 \sin \theta \cos \theta = 2 \cdot \frac{x}{2} \cdot \frac{\sqrt{4-x^2}}{2} = \frac{1}{2}x\sqrt{4-x^2}$$

and

$$\begin{aligned} \sin 4\theta &= 2 \sin 2\theta \cos 2\theta = 2 \cdot \frac{1}{2}x\sqrt{4-x^2} \cdot (\cos^2\theta - \sin^2\theta) \\ &= x\sqrt{4-x^2} \cdot \left(\frac{4-x^2}{4} - \frac{x^2}{4} \right) = x\sqrt{4-x^2} \cdot \frac{4-2x^2}{4} = \frac{1}{2}x\sqrt{4-x^2}(2-x^2), \end{aligned}$$

and so an antiderivative is

$$\begin{aligned} \frac{8}{3} \int (\sqrt{4-x^2})^3 dx &= 16\theta + \frac{32}{3}\sin 2\theta + \frac{4}{3}\sin 4\theta \\ &= 16\sin^{-1}\left(\frac{x}{2}\right) + \frac{32}{3} \cdot \frac{1}{2}x\sqrt{4-x^2} + \frac{4}{3} \cdot \frac{1}{2}x\sqrt{4-x^2}(2-x^2) \\ &= 16\sin^{-1}\left(\frac{x}{2}\right) + \frac{16}{3}x\sqrt{4-x^2} + \frac{2}{3}x\sqrt{4-x^2}(2-x^2) \\ &= 16\sin^{-1}\left(\frac{x}{2}\right) + \frac{2}{3}x\sqrt{4-x^2} \cdot (8 + (2-x^2)) \\ &= 16\sin^{-1}\left(\frac{x}{2}\right) + \frac{2}{3}x(10-x^2)\sqrt{4-x^2}. \end{aligned}$$

Now we can finish evaluating the volume:

$$\begin{aligned}
 V &= \frac{8}{3} \int_0^2 \left(\sqrt{4-x^2} \right)^3 dx = \left[16 \sin^{-1} \left(\frac{x}{2} \right) + \frac{2}{3} x(10-x^2) \sqrt{4-x^2} \right]_0^2 \\
 &= \left(16 \sin^{-1}(1) + \frac{2}{3} \cdot 2 \cdot (10-4) \sqrt{4-4} \right) - \left(16 \sin^{-1}(0) + \frac{2}{3} \cdot 0 \cdot (10-0) \sqrt{4-0} \right) \\
 &= \left(16 \cdot \frac{\pi}{2} + 0 \right) - (0+0) = \boxed{8\pi \text{ cubic units}}.
 \end{aligned}$$

56. We begin by graphing the solid S enclosed by the surfaces $x^2 + y^2 = 1$, $z = x$, and $z = x^2$. This solid lies between the surfaces $z = f_1(x, y) = x^2$ and $z = f_2(x, y) = x$ over the region R in the xy -plane, that is a half-disk $x^2 + y^2 \leq 1$, $x \geq 0$; see the figures below. Notice that the solid S is symmetric, because the xz -plane cuts it into two equal parts. So we can find its volume by integrating over the part of the region R lying in the first quadrant and then multiplying it by two. Observe that the first-quadrant part of R is an x -simple region: y varies from $y = 0$ to $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R [f_2(x, y) - f_1(x, y)] dA = 2 \int_0^1 \left[\int_0^{\sqrt{1-x^2}} (x - x^2) dy \right] dx = 2 \int_0^1 (x - x^2) \left[\int_0^{\sqrt{1-x^2}} dy \right] dx \\
 &= 2 \int_0^1 (x - x^2) [y]_0^{\sqrt{1-x^2}} dx = 2 \int_0^1 (x - x^2) (\sqrt{1-x^2} - 0) dx = 2 \int_0^1 (x - x^2) \sqrt{1-x^2} dx \\
 &= \int_0^1 2x\sqrt{1-x^2} dx - \int_0^1 2x^2\sqrt{1-x^2} dx.
 \end{aligned}$$

To evaluate the first integral, we make a substitution $u = 1 - x^2$; then $du = -2x dx$, so $2x dx = -du$. We also change the limits of integration: if $x = 0$, then $u = 1 - 0^2 = 1$; if $x = 1$, then $u = 1 - 1^2 = 0$. So

$$\int_0^1 2x\sqrt{1-x^2} dx = \int_1^0 \sqrt{u} (-du) = - \int_1^0 \sqrt{u} du = \int_0^1 u^{1/2} du = \left[\frac{u^{3/2}}{3/2} \right]_0^1 = \left[\frac{2}{3} u^{3/2} \right]_0^1 = \frac{2}{3} - 0 = \frac{2}{3}.$$

To evaluate the second integral, we will find an antiderivative using a substitution $x = \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = \cos \theta d\theta$. Also,

$$\sqrt{1-x^2} = \sqrt{1-\sin^2 \theta} = \sqrt{\cos^2 \theta} = \cos \theta,$$

and the integral becomes

$$\begin{aligned}
 \int 2x^2 \sqrt{1-x^2} dx &= \int 2(\sin \theta)^2 \cos \theta \cdot \cos \theta d\theta = 2 \int \sin^2 \theta \cos^2 \theta d\theta \\
 &= 2 \int \left(\frac{1}{2} \sin 2\theta \right)^2 d\theta = \frac{1}{2} \int \sin^2 2\theta d\theta = \frac{1}{2} \int \frac{1}{2} (1 - \cos 4\theta) d\theta \\
 &= \frac{1}{4} \int (1 - \cos 4\theta) d\theta = \frac{1}{4} \left(\theta - \frac{1}{4} \sin 4\theta \right) = \frac{1}{4} \theta - \frac{1}{16} \sin 4\theta.
 \end{aligned}$$

To express this antiderivative in terms of x , we first observe that since $x = \sin \theta$, then $\theta = \sin^{-1}(x)$. Also, as shown above, $\cos \theta = \sqrt{1-x^2}$. Then

$$\begin{aligned}
 \sin 4\theta &= 2 \sin 2\theta \cos 2\theta = 2 \cdot 2 \sin \theta \cos \theta \cdot (\cos^2 \theta - \sin^2 \theta) \\
 &= 4x \sqrt{1-x^2} \cdot (1-x^2-x^2) = 4x(1-2x^2)\sqrt{1-x^2},
 \end{aligned}$$

and so an antiderivative is

$$\begin{aligned}
 \int 2x^2 \sqrt{1-x^2} dx &= \frac{1}{4} \theta - \frac{1}{16} \sin 4\theta = \frac{1}{4} \sin^{-1}(x) - \frac{1}{16} \cdot 4x(1-2x^2)\sqrt{1-x^2} \\
 &= \frac{1}{4} \sin^{-1}(x) - \frac{1}{4} x(1-2x^2)\sqrt{1-x^2}.
 \end{aligned}$$

Now we can finish evaluating the second integral:

$$\begin{aligned}
 \int_0^1 2x^2 \sqrt{1-x^2} dx &= \left[\frac{1}{4} \sin^{-1}(x) - \frac{1}{4} x(1-2x^2)\sqrt{1-x^2} \right]_0^1 \\
 &= \left(\frac{1}{4} \sin^{-1}(1) - \frac{1}{4} \cdot 1 \cdot (1-2)\sqrt{1-1} \right) - \left(\frac{1}{4} \sin^{-1}(0) - \frac{1}{4} \cdot 0 \cdot (1-0)\sqrt{1-0} \right) \\
 &= \left(\frac{1}{4} \cdot \frac{\pi}{2} - 0 \right) - (0-0) = \frac{\pi}{8}.
 \end{aligned}$$

The final answer is

$$V = \int_0^1 2x \sqrt{1-x^2} dx - \int_0^1 2x^2 \sqrt{1-x^2} dx = \boxed{\frac{2}{3} - \frac{\pi}{8} \text{ cubic units}}.$$

57. The solid S bounded from above by the circular paraboloid $z = f(x, y) = 1 - x^2 - y^2$, from below by the xy -plane, and on the sides by the cylinder $x^2 + y^2 = 1$ is shown in the figure in Problem 57. It lies above the region R in the xy -plane, that is the disk $x^2 + y^2 \leq 1$. Notice that the solid S is symmetric, consisting of four equal parts over each quadrant. So we can find its volume by integrating over the part of the region R lying in the first quadrant and then multiplying it by four. Observe that the

first-quadrant part of R is an x -simple region: y varies from $y = 0$ to $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. So the volume V of the solid S is

$$\begin{aligned} V &= \iint_R f(x, y) dA = 4 \int_0^1 \left[\int_0^{\sqrt{1-x^2}} (x^2 + y^2) dy \right] dx \\ &= 4 \int_0^1 \left[x^2 y + \frac{y^3}{3} \right]_0^{\sqrt{1-x^2}} dx = 4 \int_0^1 \left[\left(x^2 \sqrt{1-x^2} + \frac{(\sqrt{1-x^2})^3}{3} \right) - 0 \right] dx \\ &= \frac{4}{3} \int_0^1 \left[3x^2 \sqrt{1-x^2} + (1-x^2) \sqrt{1-x^2} \right] dx = \frac{4}{3} \int_0^1 (1+2x^2) \sqrt{1-x^2} dx. \end{aligned}$$

In this integral, we make a substitution $x = \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = \cos \theta d\theta$. Also, $\sqrt{1-x^2} = \sqrt{1-\sin^2 \theta} = \sqrt{\cos^2 \theta} = \cos \theta$. The limits of integration can be recalculated as follows: if $x = 0$, then $\sin \theta = 0$ and $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ imply that $\theta = 0$; if $x = 1$, then $\sin \theta = 1$ and $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ imply that $\theta = \frac{\pi}{2}$. So the integral becomes

$$\begin{aligned} V &= \frac{4}{3} \int_0^1 (1+2x^2) \sqrt{1-x^2} dx = \frac{4}{3} \int_0^{\pi/2} (1+2\sin^2 \theta) \cos \theta \cdot \cos \theta d\theta \\ &= \int_0^{\pi/2} \left(\frac{4}{3} \cos^2 \theta + \frac{8}{3} \sin^2 \theta \cos^2 \theta \right) d\theta \\ &= \int_0^{\pi/2} \left(\frac{4}{3} \cdot \frac{1}{2} (1 + \cos 2\theta) + \frac{8}{3} \left(\frac{1}{2} \sin 2\theta \right)^2 \right) d\theta \\ &= \int_0^{\pi/2} \left(\frac{2}{3} + \frac{2}{3} \cos 2\theta + \frac{2}{3} \sin^2 2\theta \right) d\theta \\ &= \int_0^{\pi/2} \left(\frac{2}{3} + \frac{2}{3} \cos 2\theta + \frac{2}{3} \cdot \frac{1}{2} (1 - \cos 4\theta) \right) d\theta \\ &= \int_0^{\pi/2} \left(\frac{2}{3} + \frac{2}{3} \cos 2\theta + \frac{1}{3} - \frac{1}{3} \cos 4\theta \right) d\theta \\ &= \int_0^{\pi/2} \left(1 + \frac{2}{3} \cos 2\theta - \frac{1}{3} \cos 4\theta \right) d\theta = \left[\theta + \frac{1}{3} \sin 2\theta - \frac{1}{12} \sin 4\theta \right]_0^{\pi/2} \\ &= \left(\frac{\pi}{2} + \frac{1}{3} \sin \pi - \frac{1}{12} \sin 2\pi \right) - \left(0 + \frac{1}{3} \sin 0 - \frac{1}{12} \sin 0 \right) = \boxed{\frac{\pi}{2} \text{ cubic units}}. \end{aligned}$$

58. We begin by graphing the solid S enclosed by the parabolic cylinder $z = \frac{x^2}{2}$ and the planes $y = 0$, $y = x$, $x = 2$, and $z = 0$. This solid lies under the surface $z = f(x, y) = \frac{x^2}{2}$ over the region R in the xy -plane, that is the triangular region bounded by the lines $y = 0$, $y = x$, and $x = 2$; see the figures below. Observe that R is an x -simple region: y varies from $y = 0$ to $y = x$, where $0 \leq x \leq 2$. So the volume V of the solid S is

$$\begin{aligned} V &= \iint_R f(x, y) dA = \int_0^2 \left[\int_0^x \frac{x^2}{2} dy \right] dx = \int_0^2 \frac{x^2}{2} \left[\int_0^x dy \right] dx = \int_0^2 \frac{x^2}{2} [y]_0^x dx \\ &= \int_0^2 \frac{x^2}{2} (x-0) dx = \int_0^2 \frac{x^3}{2} dx = \left[\frac{x^4}{8} \right]_0^2 = \frac{2^4}{8} - \frac{0^4}{8} = \boxed{2 \text{ cubic units}}. \end{aligned}$$

59. We begin by graphing the solid S enclosed by the coordinate planes, the plane $y = 3$, and the surface $z = y + 1 - x^2$. This solid lies under the surface $z = f(x, y) = y + 1 - x^2$ over the region R in the xy -plane, that is bounded by the coordinate axes, the line $y = 3$, and the curve $y = x^2 - 1$ in the first quadrant; see the figures below. Observe that R is a y -simple region: x varies from $x = 0$ to $x = \sqrt{y+1}$, where $0 \leq y \leq 3$. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) dA = \int_0^3 \left[\int_0^{\sqrt{y+1}} (y + 1 - x^2) dx \right] dy = \int_0^3 \left[(y + 1)x - \frac{x^3}{3} \right]_0^{\sqrt{y+1}} dy \\
 &= \int_0^3 \left[\left((y + 1)\sqrt{y + 1} - \frac{(\sqrt{y + 1})^3}{3} \right) - 0 \right] dy = \int_0^3 \left((y + 1)^{3/2} - \frac{(y + 1)^{3/2}}{3} \right) dy \\
 &= \int_0^3 \frac{2}{3} (y + 1)^{3/2} dy = \left[\frac{2}{3} \cdot \frac{(y + 1)^{5/2}}{5/2} \right]_0^3 = \frac{4}{15} \left[(\sqrt{y + 1})^5 \right]_0^3 \\
 &= \frac{4}{15} \left[(\sqrt{3 + 1})^5 - (\sqrt{0 + 1})^5 \right] = \frac{4}{15} (2^5 - 1^5) = \frac{4}{15} \cdot 31 = \boxed{\frac{124}{15} \text{ cubic units}}.
 \end{aligned}$$

60. We begin by graphing the solid S enclosed by the surfaces $z = xe^y$, $z = 0$, $y = 0$, $x = 1$, and $y = x^2$. This solid lies under the surface $z = f(x, y) = xe^y$ over the region R in the xy -plane, that is bounded by the x -axis, the line $x = 1$, and the curve $y = x^2$; see the figures below. Observe that R is an x -simple region: y varies from $y = 0$ to $y = x^2$, where $0 \leq x \leq 1$. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) dA = \int_0^1 \left[\int_0^{x^2} xe^y dy \right] dx = \int_0^1 x \left[\int_0^{x^2} e^y dy \right] dx = \int_0^1 x [e^y]_0^{x^2} dx \\
 &= \int_0^1 x (e^{x^2} - e^0) dx = \int_0^1 x (e^{x^2} - 1) dx = \int_0^1 xe^{x^2} dx - \int_0^1 x dx.
 \end{aligned}$$

The second integral can be evaluated directly as

$$\int_0^1 x \, dx = \left[\frac{x^2}{2} \right]_0^1 = \frac{1}{2} - 0 = \frac{1}{2}.$$

To evaluate the first integral, we make a substitution $u = x^2$; then $du = 2x \, dx$, so $x \, dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 = 0$; if $x = 1$, then $u = 1^2 = 1$. So

$$\int_0^1 x e^{x^2} \, dx = \int_0^1 e^u \frac{du}{2} = \frac{1}{2} \int_0^1 e^u \, du = \frac{1}{2} [e^u]_0^1 = \frac{1}{2} (e^1 - e^0) = \frac{e}{2} - \frac{1}{2}.$$

So the final answer is

$$V = \left(\frac{e}{2} - \frac{1}{2} \right) - \frac{1}{2} = \boxed{\frac{e}{2} - 1 \text{ cubic units}}.$$

61. (a) The limits of integration of the iterated integral $\int_0^{\sqrt{\pi/2}} \left[\int_y^{\sqrt{\pi/2}} \sin x^2 \, dx \right] dy$ describe the region R bounded between $x = y$ and $x = \sqrt{\pi/2}$, where $0 \leq y \leq \sqrt{\pi/2}$. This is a triangular region, as shown in the figure.

- (b) Observe that R is also an x -simple region: it is bounded between $y = 0$ and $y = x$, where $0 \leq x \leq \sqrt{\pi/2}$. So according to Fubini's Theorem,

$$\int_0^{\sqrt{\pi/2}} \left[\int_y^{\sqrt{\pi/2}} \sin x^2 \, dx \right] dy = \iint_R \sin x^2 \, dA = \boxed{\int_0^{\sqrt{\pi/2}} \left[\int_0^x \sin x^2 \, dy \right] dx}.$$

(c) To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned}\int_0^{\sqrt{\pi/2}} \left[\int_0^x \sin x^2 dy \right] dx &= \int_0^{\sqrt{\pi/2}} \sin x^2 \left[\int_0^x dy \right] dx = \int_0^{\sqrt{\pi/2}} \sin x^2 [y]_0^x dx \\ &= \int_0^{\sqrt{\pi/2}} \sin x^2 \cdot (x - 0) dx = \int_0^{\sqrt{\pi/2}} x \sin x^2 dx.\end{aligned}$$

In this integral we make a substitution $u = x^2$; then $du = 2x dx$, so $x dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 = 0$; if $x = \sqrt{\frac{\pi}{2}}$, then $u = \left(\sqrt{\frac{\pi}{2}}\right)^2 = \frac{\pi}{2}$. So

$$\begin{aligned}\int_0^{\sqrt{\pi/2}} x \sin x^2 dx &= \int_0^{\pi/2} \sin u \frac{du}{2} = \frac{1}{2} \int_0^{\pi/2} \sin u du \\ &= \frac{1}{2} [-\cos u]_0^{\pi/2} = \frac{1}{2} \left(-\cos \frac{\pi}{2} + \cos 0 \right) = \frac{1}{2} (-0 + 1) = \boxed{\frac{1}{2}}.\end{aligned}$$

62. (a) The limits of integration of the iterated integral $\int_0^{1/2} \left[\int_{2x}^1 e^{y^2} dy \right] dx$ describe the region R bounded between $y = 2x$ and $y = 1$, where $0 \leq x \leq \frac{1}{2}$. This is a triangular region, as shown in the figure.

- (b) Observe that R is also a y -simple region: it is bounded between $x = 0$ and $x = \frac{y}{2}$, where $0 \leq y \leq 1$. So according to Fubini's Theorem,

$$\int_0^{1/2} \left[\int_{2x}^1 e^{y^2} dy \right] dx = \iint_R e^{y^2} dA = \boxed{\int_0^1 \left[\int_0^{y/2} e^{y^2} dx \right] dy}.$$

(c) To evaluate the iterated integral in part (b), we first integrate partially with respect to x :

$$\begin{aligned}\int_0^1 \left[\int_0^{y/2} e^{y^2} dx \right] dy &= \int_0^1 e^{y^2} \left[\int_0^{y/2} dx \right] dy = \int_0^1 e^{y^2} [x]_0^{y/2} dy \\ &= \int_0^1 e^{y^2} \cdot \left(\frac{y}{2} - 0 \right) dy = \frac{1}{2} \int_0^1 y e^{y^2} dy.\end{aligned}$$

In this integral we make a substitution $u = y^2$; then $du = 2y dy$, so $y dy = \frac{du}{2}$. We also change

the limits of integration: if $y = 0$, then $u = 0^2 = 0$; if $y = 1$, then $u = 1^2 = 1$. So

$$\begin{aligned} \frac{1}{2} \int_0^1 y e^{y^2} dy &= \frac{1}{2} \int_0^1 e^u \frac{du}{2} = \frac{1}{4} \int_0^1 e^u du \\ &= \frac{1}{4} [e^u]_0^1 = \frac{1}{4} (e^1 - e^0) = \frac{1}{4} (e - 1) = \boxed{\frac{e - 1}{4}}. \end{aligned}$$

63. (a) The limits of integration of the iterated integral $\int_0^1 \left[\int_0^{\sqrt{1-x^2}} \frac{1}{\sqrt{1-y^2}} dy \right] dx$ describe the region R bounded between $y = 0$ and $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. This is a quarter-disk of radius 1 lying in the first quadrant, as shown in the figure.

- (b) Observe that R is also a y -simple region: it is bounded between $x = 0$ and $x = \sqrt{1-y^2}$, where $0 \leq y \leq 1$. So according to Fubini's Theorem,

$$\int_0^1 \left[\int_0^{\sqrt{1-y^2}} \frac{1}{\sqrt{1-y^2}} dx \right] dy = \iint_R \frac{1}{\sqrt{1-y^2}} dA = \boxed{\int_0^1 \left[\int_0^{\sqrt{1-y^2}} \frac{1}{\sqrt{1-y^2}} dx \right] dy}.$$

- (c) To evaluate the iterated integral in part (b), we first integrate partially with respect to x :

$$\begin{aligned} \int_0^1 \left[\int_0^{\sqrt{1-y^2}} \frac{1}{\sqrt{1-y^2}} dx \right] dy &= \int_0^1 \frac{1}{\sqrt{1-y^2}} \left[\int_0^{\sqrt{1-y^2}} dx \right] dy \\ &= \int_0^1 \frac{1}{\sqrt{1-y^2}} [x]_0^{\sqrt{1-y^2}} dy = \int_0^1 \frac{1}{\sqrt{1-y^2}} \cdot (\sqrt{1-y^2} - 0) dy \\ &= \int_0^1 1 dy = [y]_0^1 = 1 - 0 = \boxed{1}. \end{aligned}$$

64. (a) The limits of integration of the iterated integral $\int_0^1 \left[\int_y^1 \frac{\sin x}{x} dx \right] dy$ describe the region R bounded between $x = y$ and $x = 1$, where $0 \leq y \leq 1$. This is a triangular region, as shown in the figure.

- (b) Observe that R is also an x -simple region: it is bounded between $y = 0$ and $y = x$, where $0 \leq x \leq 1$. So according to Fubini's Theorem,

$$\int_0^1 \left[\int_y^1 \frac{\sin x}{x} dx \right] dy = \iint_R \frac{\sin x}{x} dA = \boxed{\int_0^1 \left[\int_0^x \frac{\sin x}{x} dy \right] dx}.$$

- (c) To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_0^x \frac{\sin x}{x} dy \right] dx &= \int_0^1 \frac{\sin x}{x} \left[\int_0^x dy \right] dx = \int_0^1 \frac{\sin x}{x} [y]_0^x dx = \int_0^1 \frac{\sin x}{x} \cdot (x - 0) dx \\ &= \int_0^1 \sin x dx = [-\cos x]_0^1 = -\cos 1 + \cos 0 = \boxed{1 - \cos 1}. \end{aligned}$$

65. (a) The limits of integration of the iterated integral $\int_0^1 \left[\int_y^1 \sqrt{2+x^2} dx \right] dy$ describe the region R bounded between $x = y$ and $x = 1$, where $0 \leq y \leq 1$. This is a triangular region, as shown in the figure.

- (b) Observe that R is also an x -simple region: it is bounded between $y = 0$ and $y = x$, where $0 \leq x \leq 1$. So according to Fubini's Theorem,

$$\int_0^1 \left[\int_y^1 \sqrt{2+x^2} dx \right] dy = \iint_R \sqrt{2+x^2} dA = \boxed{\int_0^1 \left[\int_0^x \sqrt{2+x^2} dy \right] dx}.$$

- (c) To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned} \int_0^1 \left[\int_0^x \sqrt{2+x^2} dy \right] dx &= \int_0^1 \sqrt{2+x^2} \left[\int_0^x dy \right] dx = \int_0^1 \sqrt{2+x^2} [y]_0^x dx \\ &= \int_0^1 \sqrt{2+x^2} \cdot (x - 0) dx = \int_0^1 x\sqrt{2+x^2} dx. \end{aligned}$$

In this integral we make a substitution $u = 2 + x^2$; then $du = 2x dx$, so $x dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 2 + 0^2 = 2$; if $x = 1$, then $u = 2 + 1^2 = 3$. So

$$\begin{aligned} \int_0^1 x\sqrt{2+x^2} dx &= \int_2^3 \sqrt{u} \frac{du}{2} = \frac{1}{2} \int_2^3 u^{1/2} du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_2^3 \\ &= \frac{1}{3} \left[(\sqrt{u})^3 \right]_2^3 = \frac{1}{3} \left((\sqrt{3})^3 - (\sqrt{2})^3 \right) = \frac{3\sqrt{3} - 2\sqrt{2}}{3} = \boxed{\sqrt{3} - \frac{2\sqrt{2}}{3}}. \end{aligned}$$

66. (a) The limits of integration of the iterated integral $\int_0^1 \left[\int_{\sqrt[3]{x}}^1 \sqrt{1+y^4} dy \right] dx$ describe the region R bounded between $y = \sqrt[3]{x}$ and $y = 1$, where $0 \leq x \leq 1$; see the figure.

- (b) Observe that R is also a y -simple region: it is bounded between $x = 0$ and $x = y^3$, where $0 \leq y \leq 1$. So according to Fubini's Theorem,

$$\int_0^1 \left[\int_{\sqrt[3]{x}}^1 \sqrt{1+y^4} dy \right] dx = \iint_R \sqrt{1+y^4} dA = \boxed{\int_0^1 \left[\int_0^{y^3} \sqrt{1+y^4} dx \right] dy}.$$

- (c) To evaluate the iterated integral in part (b), we first integrate partially with respect to x :

$$\begin{aligned} \int_0^1 \left[\int_0^{y^3} \sqrt{1+y^4} dx \right] dy &= \int_0^1 \sqrt{1+y^4} \left[\int_0^{y^3} dx \right] dy = \int_0^1 \sqrt{1+y^4} [x]_0^{y^3} dy \\ &= \int_0^1 \sqrt{1+y^4} \cdot (y^3 - 0) dy = \int_0^1 y^3 \sqrt{1+y^4} dy. \end{aligned}$$

In this integral we make a substitution $u = 1 + y^4$; then $du = 4y^3 dy$, so $y^3 dy = \frac{du}{4}$. We also change the limits of integration: if $y = 0$, then $u = 1 + 0^4 = 1$; if $y = 1$, then $u = 1 + 1^4 = 2$. So

$$\begin{aligned} \int_0^1 y^3 \sqrt{1+y^4} dy &= \int_1^2 \sqrt{u} \frac{du}{4} = \frac{1}{4} \int_1^2 u^{1/2} du = \frac{1}{4} \left[\frac{u^{3/2}}{3/2} \right]_1^2 \\ &= \frac{1}{6} \left[(\sqrt{u})^3 \right]_1^2 = \frac{1}{6} \left((\sqrt{2})^3 - (\sqrt{1})^3 \right) = \boxed{\frac{2\sqrt{2}-1}{6}}. \end{aligned}$$

67. (a) The limits of integration of the iterated integral $\int_0^1 \left[\int_{\sqrt{y}}^1 e^{y/x} dx \right] dy$ describe the region R bounded between $x = \sqrt{y}$ and $x = 1$, where $0 \leq y \leq 1$; see the figure.

- (b) Observe that R is also an x -simple region: it is bounded between $y = 0$ and $y = x^2$, where $0 \leq x \leq 1$. So according to Fubini's Theorem,

$$\int_0^1 \left[\int_{\sqrt{y}}^1 e^{y/x} dx \right] dy = \iint_R e^{y/x} dA = \boxed{\int_0^1 \left[\int_0^{x^2} e^{y/x} dy \right] dx}.$$

- (c) To evaluate the iterated integral in part (b), we first find the integral in the brackets by integrating partially with respect to y treating x as a constant. We make a substitution $u = \frac{y}{x}$; then $du = \frac{1}{x} dy$, so $dy = x du$. We also change the limits of integration: if $y = 0$, then $u = \frac{0}{x} = 0$; if $y = x^2$, then $u = \frac{x^2}{x} = x$. So:

$$\int_0^{x^2} e^{y/x} dy = \int_0^x e^u \cdot x du = x \int_0^x e^u du = x[e^u]_0^x = x(e^x - e^0) = x(e^x - 1).$$

Going back to the iterated integral, we obtain

$$\int_0^1 \left[\int_0^{x^2} e^{y/x} dy \right] dx = \int_0^1 x(e^x - 1) dx = \int_0^1 x e^x dx - \int_0^1 x dx.$$

The second integral can be evaluated directly as

$$\int_0^1 x dx = \left[\frac{x^2}{2} \right]_0^1 = \frac{1}{2} - 0 = \frac{1}{2}.$$

To find the first integral, we use the method of integration by parts. If we choose $u = x$ and $dv = e^x dx$, then $du = dx$ and $v = \int e^x dx = e^x$. So

$$\int_0^1 x e^x dx = [x e^x]_0^1 - \int_0^1 e^x dx = (1e^1 - 0e^0) - [e^x]_0^1 = e - (e^1 - e^0) = e - e + 1 = 1.$$

The final answer is

$$\int_0^1 x e^x dx - \int_0^1 x dx = 1 - \frac{1}{2} = \boxed{\frac{1}{2}}.$$

68. (a) The limits of integration of the iterated integral $\int_0^1 \left[\int_{\sin^{-1} y}^{\pi/2} e^{\cos x} dx \right] dy$ describe the region R bounded between $x = \sin^{-1} y$ and $x = \frac{\pi}{2}$, where $0 \leq y \leq 1$; see the figure.

- (b) Observe that R is also an x -simple region: it is bounded between $y = 0$ and $y = \sin x$, where $0 \leq x \leq \frac{\pi}{2}$. So according to Fubini's Theorem,

$$\int_0^1 \left[\int_{\sin^{-1} y}^{\pi/2} e^{\cos x} dx \right] dy = \iint_R e^{\cos x} dA = \boxed{\int_0^{\pi/2} \left[\int_0^{\sin x} e^{\cos x} dy \right] dx}.$$

(c) To evaluate the iterated integral in part (b), we first integrate partially with respect to y :

$$\begin{aligned}\int_0^{\pi/2} \left[\int_0^{\sin x} e^{\cos x} dy \right] dx &= \int_0^{\pi/2} e^{\cos x} \left[\int_0^{\sin x} dy \right] dx = \int_0^{\pi/2} e^{\cos x} [y]_0^{\sin x} dx \\ &= \int_0^{\pi/2} e^{\cos x} \cdot (\sin x - 0) dx = \int_0^{\pi/2} \sin x e^{\cos x} dx.\end{aligned}$$

In this integral we make a substitution $u = \cos x$; then $du = -\sin x dx$, so $\sin x dx = -du$. We also change the limits of integration: if $x = 0$, then $u = \cos 0 = 1$; if $x = \frac{\pi}{2}$, then $u = \cos \frac{\pi}{2} = 0$. So

$$\int_0^{\pi/2} \sin x e^{\cos x} dx = \int_1^0 e^u (-du) = -\int_1^0 e^u du = \int_0^1 e^u du = [e^u]_0^1 = e^1 - e^0 = \boxed{e - 1}.$$

69. Let $B = \iint_R f(x, y) dA$, $C = \iint_{R_1} f(x, y) dA$, and $D = \iint_{R_2} f(x, y) dA$ be the values of these three double integrals. By properties of double integrals, $\iint_R 3f(x, y) dA = 3 \iint_R f(x, y) dA$, and the first given equation can be rewritten as

$$3 \iint_R f(x, y) dA - 2 \iint_{R_1} f(x, y) dA = \iint_{R_2} f(x, y) dA \quad \text{or} \quad 3B - 2C = D.$$

Similarly, $\iint_{R_2} 5f(x, y) dA = 5 \iint_{R_2} f(x, y) dA$, and the second given equation can be rewritten as

$$5 \iint_{R_2} f(x, y) dA - 2 \iint_{R_1} f(x, y) dA = 18 \quad \text{or} \quad 5D - 2C = 18.$$

Also, since the region R is partitioned into subregions R_1 and R_2 , that have no points in common except some portions of their common boundary, by properties of double integrals

$$\iint_{R_1} f(x, y) dA + \iint_{R_2} f(x, y) dA = \iint_R f(x, y) dA \quad \text{or} \quad C + D = B.$$

So we need to solve a system of three linear equations with three unknowns (in fact, we are only asked to find the unknown $B = \iint_R f(x, y) dA$):

$$\begin{cases} 3B - 2C = D \\ 5D - 2C = 18 \\ C + D = B \end{cases}$$

Substituting $B = C + D$ into the first equation yields

$$3B - 2C = D, \text{ so } 3(C + D) - 2C = D, \text{ so } 3C + 3D - 2C = D, \text{ so } C = -2D.$$

Substituting $C = -2D$ into the second equation yields

$$5D - 2C = 18, \text{ so } 5D - 2(-2D) = 18, \text{ so } 9D = 18, \text{ so } D = 2.$$

Now we can find that $C = -2D = -2 \cdot 2 = -4$ and $\iint_R f(x, y) dA = B = C + D = -4 + 2 = \boxed{-2}$.

70. Let $B = \iint_R f(x, y) dA$, $C = \iint_{R_1} f(x, y) dA$, and $D = \iint_{R_2} f(x, y) dA$ be the values of these three double integrals. By properties of double integrals, $\iint_{R_2} 3f(x, y) dA = 3 \iint_{R_2} f(x, y) dA$, and the first given equation can be rewritten as

$$3 \iint_{R_2} f(x, y) dA - \iint_{R_1} f(x, y) dA = 2 \iint_R f(x, y) dA \quad \text{or} \quad 3D - C = 2B.$$

Similarly, $\iint_{R_1} 4f(x, y) dA = 4 \iint_{R_1} f(x, y) dA$ and $\iint_{R_2} 2f(x, y) dA = 2 \iint_{R_2} f(x, y) dA$, and the second given equation can be rewritten as

$$4 \iint_{R_1} f(x, y) dA + 2 \iint_{R_2} f(x, y) dA = 7 \quad \text{or} \quad 4C + 2D = 7.$$

Also, since the region R is partitioned into subregions R_1 and R_2 , that have no points in common except some portions of their common boundary, by properties of double integrals

$$\iint_{R_1} f(x, y) dA + \iint_{R_2} f(x, y) dA = \iint_R f(x, y) dA \quad \text{or} \quad C + D = B.$$

So we need to solve a system of three linear equations with three unknowns (in fact, we are only asked to find the unknown $B = \iint_R f(x, y) dA$):

$$\begin{cases} 3D - C = 2B \\ 4C + 2D = 7 \\ C + D = B \end{cases}$$

Substituting $B = C + D$ into the first equation yields

$$3D - C = 2B, \text{ so } 3D - C = 2(C + D), \text{ so } 3D - C = 2C + 2D, \text{ so } D = 3C.$$

Substituting $D = 3C$ into the second equation yields

$$4C + 2D = 7, \text{ so } 4C + 2 \cdot 3C = 7, \text{ so } 10C = 7, \text{ so } C = \frac{7}{10}.$$

Now we can find that $D = 3C = 3 \cdot \frac{7}{10} = \frac{21}{10}$ and $\iint_R f(x, y) dA = B = C + D = \frac{7}{10} + \frac{21}{10} = \frac{28}{10} = \boxed{\frac{14}{5}}.$

71. Let $C = \iint_{R_1} f(x, y) dA$, and $D = \iint_{R_2} f(x, y) dA$ be the values of the double integrals over the two subregions. Then the first given equation can be rewritten as

$$2 \iint_{R_2} f(x, y) dA - 7 \iint_{R_1} f(x, y) dA = 17 \quad \text{or} \quad 2D - 7C = 17,$$

and the second given equation can be rewritten as

$$\iint_{R_2} f(x, y) dA - 2 \iint_{R_1} f(x, y) dA = 7 \quad \text{or} \quad D - 2C = 7,$$

giving rise to a system of two linear equations with two unknowns:

$$\begin{cases} 2D - 7C = 17 \\ D - 2C = 7 \end{cases}$$

From the second equation we find that $D = 7 + 2C$, and substituting that into the first equation yields

$$2D - 7C = 17, \text{ so } 2(7 + 2C) - 7C = 17, \text{ so } 14 + 4C - 7C = 17, \text{ so } -3C = 3, \text{ so } C = \frac{3}{-3} = -1.$$

Then $D = 7 + 2C = 7 + 2 \cdot (-1) = 5$.

Finally, since the region R is partitioned into subregions R_1 and R_2 , that have no points in common except some portions of their common boundary, by properties of double integrals we find that

$$\iint_R f(x, y) dA = \iint_{R_1} f(x, y) dA + \iint_{R_2} f(x, y) dA = C + D = (-1) + 5 = \boxed{4}.$$

72. Let $C = \iint_{R_1} f(x, y) dA$, and $D = \iint_{R_2} f(x, y) dA$ be the values of the double integrals over the two subregions. By properties of double integrals, $\iint_{R_2} 6f(x, y) dA = 6 \iint_{R_2} f(x, y) dA$, and the first given equation can be rewritten as

$$6 \iint_{R_2} f(x, y) dA - 3 \iint_{R_1} f(x, y) dA = -12 \quad \text{or} \quad 6D - 3C = -12.$$

Similarly, $\iint_{R_2} 4f(x, y) dA = 4 \iint_{R_2} f(x, y) dA$, and the second given equation can be rewritten as

$$4 \iint_{R_2} f(x, y) dA + 2 = \iint_{R_1} f(x, y) dA \quad \text{or} \quad 4D + 2 = C.$$

So we have a system of two linear equations with two unknowns:

$$\begin{cases} 6D - 3C = -12 \\ 4D + 2 = C \end{cases}$$

We can simplify the first equation dividing it through by 3 to obtain $2D - C = -4$ or $C = 2D + 4$. Since from the second equation $C = 4D + 2$, we can eliminate C : $2D + 4 = 4D + 2$, so $-2D = -2$, so $D = 1$. Then $C = 4D + 2 = 4 \cdot 1 + 2 = 6$.

Finally, since the region R is partitioned into subregions R_1 and R_2 , that have no points in common except some portions of their common boundary, by properties of double integrals we find that

$$\iint_R f(x, y) dA = \iint_{R_1} f(x, y) dA + \iint_{R_2} f(x, y) dA = C + D = 6 + 1 = \boxed{7}.$$

73. The limits of integration of the iterated integral $\int_0^1 \left[\int_0^{\sqrt{1-x^2}} \sqrt{1-x^2-y^2} dy \right] dx$ describe the region R in the xy -plane defined by $0 \leq y \leq \sqrt{1-x^2}$, $0 \leq x \leq 1$; this region is the first-quadrant quarter of the disk of radius 1 centered at the origin, as shown in figure (a) below. According to Fubini's Theorem, $\int_0^1 \left[\int_0^{\sqrt{1-x^2}} \sqrt{1-x^2-y^2} dy \right] dx = \iint_R \sqrt{1-x^2-y^2} dA$. Since the integrand is nonnegative on R , this double integral represents the volume of the solid under the surface $z = f(x, y) = \sqrt{1-x^2-y^2}$ over the region R . This is the solid bounded by the hemisphere $z = \sqrt{1-x^2-y^2}$ and the coordinate planes in the first octant, as shown in figure (b) below.

(a)

(b)

74. The limits of integration of the iterated integral $\int_0^2 \left[\int_0^{\sqrt{4-y^2}} (4-x^2-y^2) dx \right] dy$ describe the region R in the xy -plane defined by $0 \leq x \leq \sqrt{4-y^2}$, $0 \leq y \leq 2$; this region is the first-quadrant quarter of the disk of radius 2 centered at the origin, as shown in figure (a) below. According to Fubini's Theorem, $\int_0^2 \left[\int_0^{\sqrt{4-y^2}} (4-x^2-y^2) dx \right] dy = \iint_R (4-x^2-y^2) dA$. Since the integrand is nonnegative on R , this double integral represents the volume of the solid under the surface $z = f(x, y) = 4 - x^2 - y^2$ over the region R . This is the solid bounded by the circular paraboloid $z = 4 - x^2 - y^2$ and the coordinate planes in the first octant, as shown in figure (b) below.

(a)

(b)

75. The limits of integration of the iterated integral $\int_0^4 \left[\int_0^1 3 dy \right] dx$ describe the rectangular region R defined by $0 \leq x \leq 4$, $0 \leq y \leq 1$. According to Fubini's Theorem, $\int_0^4 \left[\int_0^1 3 dy \right] dx = \iint_R 3 dA$. Since the integrand is nonnegative on R , this double integral represents the volume of the solid under the surface $z = f(x, y) = 3$ over the region R . This solid is a rectangular box with height $z = 3$ units, with a rectangular base of dimensions $x = 4$ units by $y = 1$ unit, as shown in the figure.

76. The limits of integration of the iterated integral $\int_0^1 \left[\int_0^2 2 dy \right] dx$ describe the rectangular region R defined by $0 \leq x \leq 1$, $0 \leq y \leq 2$. According to Fubini's Theorem, $\int_0^1 \left[\int_0^2 2 dy \right] dx = \iint_R 2 dA$. Since the integrand is nonnegative on R , this double integral represents the volume of the solid under the surface $z = f(x, y) = 2$ over the region R . This solid is a rectangular box with height $z = 2$ units, with a rectangular base of dimensions $x = 1$ unit by $y = 2$ units, as shown in the figure.

77. (a) Let R be the region enclosed by the circle of radius 1 centered at the origin, that is by the circle $x^2 + y^2 = 1$; see the figure. Notice that it is an x -simple region: y varies from $y = -\sqrt{1-x^2}$ to $y = \sqrt{1-x^2}$, where $-1 \leq x \leq 1$. According to Fubini's Theorem,

$$\begin{aligned} \iint_R x \, dA &= \int_{-1}^1 \left[\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} x \, dy \right] dx = \int_{-1}^1 x \left[\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} dy \right] dx = \int_{-1}^1 x [y]_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} dx \\ &= \int_{-1}^1 x \left[\sqrt{1-x^2} - (-\sqrt{1-x^2}) \right] dx = \int_{-1}^1 2x\sqrt{1-x^2} \, dx. \end{aligned}$$

In this integral we make a substitution $u = 1 - x^2$; then $du = -2x dx$, so $2x dx = -du$. We also change the limits of integration: if $x = -1$, then $u = 1 - (-1)^2 = 0$; if $x = 1$, then $u = 1 - 1^2 = 0$. So

$$\int_{-1}^1 2x\sqrt{1-x^2} \, dx = \int_0^0 \sqrt{u} (-du) = \boxed{0}$$

by properties of definite integrals.

- (b) Let R_1 be the region in the first quadrant enclosed by the circle of radius 1 centered at the origin, that is by the circle $x^2 + y^2 = 1$; see the figure. Notice that it is an x -simple region: y varies from $y = 0$ to $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. According to Fubini's Theorem,

$$\begin{aligned} 4 \iint_{R_1} x \, dA &= 4 \int_0^1 \left[\int_0^{\sqrt{1-x^2}} x \, dy \right] dx = 4 \int_0^1 x \left[\int_0^{\sqrt{1-x^2}} dy \right] dx \\ &= 4 \int_0^1 x [y]_0^{\sqrt{1-x^2}} dx = 4 \int_0^1 x \left[\sqrt{1-x^2} - 0 \right] dx = 4 \int_0^1 x\sqrt{1-x^2} \, dx. \end{aligned}$$

In this integral we make a substitution $u = 1 - x^2$; then $du = -2x dx$, so $x dx = \frac{du}{-2}$. We also

change the limits of integration: if $x = 0$, then $u = 1 - 0^2 = 1$; if $x = 1$, then $u = 1 - 1^2 = 0$. So

$$\begin{aligned} 4 \int_0^1 x \sqrt{1-x^2} dx &= 4 \int_1^0 \sqrt{u} \frac{du}{-2} = -2 \int_1^0 \sqrt{u} du \\ &= 2 \int_0^1 u^{1/2} du = 2 \left[\frac{u^{3/2}}{3/2} \right]_0^1 = \frac{4}{3} \left[u^{3/2} \right]_0^1 = \frac{4}{3}(1-0) = \boxed{\frac{4}{3}}. \end{aligned}$$

78. (a) To evaluate the given iterated integral, we first integrate partially with respect to y :

$$\int_1^e \left[\int_0^{\ln x} \frac{dy}{x} \right] dx = \int_1^e \frac{1}{x} \left[\int_0^{\ln x} dy \right] dx = \int_1^e \frac{1}{x} [y]_0^{\ln x} dx = \int_1^e \frac{1}{x} (\ln x - 0) dx = \int_1^e \frac{\ln x}{x} dx.$$

In this integral we make a substitution $u = \ln x$; then $du = \frac{1}{x} dx$. We also change the limits of integration: if $x = 1$, then $u = \ln 1 = 0$; if $x = e$, then $u = \ln e = 1$. So

$$\int_1^e \frac{\ln x}{x} dx = \int_0^1 u du = \left[\frac{u^2}{2} \right]_0^1 = \frac{1}{2} - 0 = \boxed{\frac{1}{2}}.$$

- (b) The limits of integration of the iterated integral $\int_1^e \left[\int_0^{\ln x} \frac{dy}{x} \right] dx$ describe the region R bounded between $y = 0$ and $y = \ln x$, where $1 \leq x \leq e$; see the figure below. Observe that R is also a y -simple region: it is bounded between $x = e^y$ and $x = e$, where $0 \leq y \leq 1$. So according to Fubini's Theorem,

$$\begin{aligned} \int_1^e \left[\int_0^{\ln x} \frac{dy}{x} \right] dx &= \iint_R \frac{1}{x} dA = \int_0^1 \left[\int_{e^y}^e \frac{dx}{x} \right] dy \\ &= \int_0^1 [\ln x]_{e^y}^e dy = \int_0^1 (\ln e - \ln e^y) dy \\ &= \int_0^1 (1 - y) dy = \left[y - \frac{y^2}{2} \right]_0^1 = \left(1 - \frac{1}{2} \right) - 0 = \boxed{\frac{1}{2}}. \end{aligned}$$

79. (a) To evaluate the given iterated integral, we first integrate partially with respect to y :

$$\begin{aligned}
 \int_0^{\pi/2} \left[\int_0^{\cos x} \sin x \, dy \right] dx &= \int_0^{\pi/2} \sin x \left[\int_0^{\cos x} dy \right] dx = \int_0^{\pi/2} \sin x [y]_0^{\cos x} dx \\
 &= \int_0^{\pi/2} \sin x (\cos x - 0) dx = \int_0^{\pi/2} \sin x \cos x dx \\
 &= \int_0^{\pi/2} \frac{1}{2} \sin 2x dx = \frac{1}{2} \left[-\frac{\cos 2x}{2} \right]_0^{\pi/2} \\
 &= -\frac{1}{4} [\cos 2x]_0^{\pi/2} = -\frac{1}{4} (\cos \pi - \cos 0) = -\frac{1}{4} (-1 - 1) = \boxed{\frac{1}{2}}.
 \end{aligned}$$

- (b) The limits of integration of the iterated integral $\int_0^{\pi/2} [\int_0^{\cos x} \sin x \, dy] dx$ describe the region R bounded between $y = 0$ and $y = \cos x$, where $0 \leq x \leq \frac{\pi}{2}$; see the figure below. Observe that R is also a y -simple region: it is bounded between $x = 0$ and $x = \cos^{-1} y$, where $0 \leq y \leq 1$. So according to Fubini's Theorem,

$$\begin{aligned}
 \int_0^{\pi/2} \left[\int_0^{\cos x} \sin x \, dy \right] dx &= \iint_R \sin x \, dA = \int_0^1 \left[\int_0^{\cos^{-1} y} \sin x \, dx \right] dy \\
 &= \int_0^1 [-\cos x]_0^{\cos^{-1} y} dy = \int_0^1 (-\cos(\cos^{-1} y) + \cos 0) dy \\
 &= \int_0^1 (-y + 1) dy = \left[-\frac{y^2}{2} + y \right]_0^1 = \left(-\frac{1}{2} + 1 \right) - 0 = \boxed{\frac{1}{2}}.
 \end{aligned}$$

80. The volume of the entire half-cylinder tank can be found by multiplying the area of its side face, which is half of a disk of radius $r = 1$ m, by its length $l = 4$ m: $V_{\text{tank}} = \frac{1}{2} \pi r^2 \cdot l = \frac{1}{2} \pi \cdot 1^2 \cdot 4 = 2\pi$. Then we can find the volume of the liquid in the tank, which is filled up to a depth of a meters, as shown in the figure in Problem 80, if we find the volume of the empty cap above the liquid level and subtract it from the volume of the tank.

The side of the tank that lies in the xz -plane is bounded by the semicircle $x^2 + z^2 = 1$, $z \geq 0$, or $z = \sqrt{1 - x^2}$. The horizontal line that represents the water level at $z = a$ meters crosses this semicircle, that is the surface of the tank, at the points with $x = \pm\sqrt{1 - a^2}$; see the figure below. So the empty cap above the water level can be represented as the solid enclosed between $z = f_1(x, y) = a$ and $z = f_2(x, y) = \sqrt{1 - x^2}$ over the region R in the xy -plane, that is a rectangle $-\sqrt{1 - a^2} \leq x \leq \sqrt{1 - a^2}$, $0 \leq y \leq 4$; and we can find its volume as the double integral

$$\iint_R [f_2(x, y) - f_1(x, y)] \, dA = \int_0^4 \left[\int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} (\sqrt{1-x^2} - a) \, dx \right] dy.$$

Let I be the value of the integral in the brackets; we find it by integrating with respect to x . The integral in the brackets can be split into a difference of two integrals:

$$I = \int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} (\sqrt{1-x^2} - a) \, dx = \int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} \sqrt{1-x^2} \, dx - \int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} a \, dx.$$

The second integral can be evaluated directly as

$$\int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} a \, dx = [ax]_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} = a \left[\sqrt{1-a^2} - \left(-\sqrt{1-a^2} \right) \right] = 2a\sqrt{1-a^2}.$$

To evaluate the first integral, we will find an antiderivative using a substitution $x = \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = \cos \theta d\theta$. Also, $\sqrt{1-x^2} = \sqrt{1-\sin^2 \theta} = \sqrt{\cos^2 \theta} = \cos \theta$, and the integral becomes

$$\begin{aligned} \int \sqrt{1-x^2} \, dx &= \int \cos \theta \cdot \cos \theta \, d\theta = \int \cos^2 \theta \, d\theta \\ &= \int \frac{1}{2}(1 + \cos 2\theta) \, d\theta = \frac{1}{2} \left(\theta + \frac{1}{2} \sin 2\theta \right) = \frac{1}{2}(\theta + \sin \theta \cos \theta). \end{aligned}$$

To express this antiderivative in terms of x , we first observe that since $x = \sin \theta$, then $\theta = \sin^{-1}(x)$. Also, as shown above, $\cos \theta = \sqrt{1-x^2}$. So an antiderivative is

$$\int \sqrt{1-x^2} \, dx = \frac{1}{2}(\theta + \sin \theta \cos \theta) = \frac{1}{2} \left(\sin^{-1} x + x\sqrt{1-x^2} \right).$$

Going back to the integral $\int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} \sqrt{1-x^2} \, dx$, notice that the integrand is an even function and the interval of integration is symmetric about the origin, so by properties of definite integrals

$$\begin{aligned} \int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} \sqrt{1-x^2} \, dx &= 2 \int_0^{\sqrt{1-a^2}} \sqrt{1-x^2} \, dx \\ &= 2 \left[\frac{1}{2} \left(\sin^{-1} x + x\sqrt{1-x^2} \right) \right]_0^{\sqrt{1-a^2}} = \left[\sin^{-1} x + x\sqrt{1-x^2} \right]_0^{\sqrt{1-a^2}} \\ &= \left(\sin^{-1} \sqrt{1-a^2} + \sqrt{1-a^2} \sqrt{1-(1-a^2)} \right) - (\sin^{-1} 0 + 0) \\ &= \sin^{-1} \sqrt{1-a^2} + a\sqrt{1-a^2} - 0 = \cos^{-1} a + a\sqrt{1-a^2}, \end{aligned}$$

where we also used a property of inverse trigonometric functions $\sin^{-1} \sqrt{1-t^2} = \cos^{-1} t$ if $0 \leq t \leq 1$ (see the note at the end of this solution). So the integral in the brackets is

$$I = \int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} \sqrt{1-x^2} \, dx - \int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} a \, dx = \cos^{-1} a + a\sqrt{1-a^2} - 2a\sqrt{1-a^2} = \cos^{-1} a - a\sqrt{1-a^2},$$

the volume of the empty cap is

$$\int_0^4 \left[\int_{-\sqrt{1-a^2}}^{\sqrt{1-a^2}} \left(\sqrt{1-x^2} - a \right) dx \right] dy = \int_0^4 I \, dy = I[y]_0^4 = I \cdot (4-0) = 4I = 4 \left(\cos^{-1} a - a\sqrt{1-a^2} \right),$$

and the volume of the liquid is

$$V_{\text{liquid}} = V_{\text{tank}} - V_{\text{cap}} = 2\pi - 4 \left(\cos^{-1} a - a\sqrt{1-a^2} \right) = \boxed{2\pi - 4 \cos^{-1} a + 4a\sqrt{1-a^2} \, \text{m}^3}.$$

Note: to prove the property $\sin^{-1} \sqrt{1-t^2} = \cos^{-1} t$ if $0 \leq t \leq 1$, let $\alpha = \sin^{-1} \sqrt{1-t^2}$. Since $0 \leq \sqrt{1-t^2} \leq 1$, α lies in the first quadrant, that is $0 \leq \alpha \leq \frac{\pi}{2}$, and therefore $\cos \alpha \geq 0$. Then we can calculate $\cos \alpha = \sqrt{1 - \sin^2 \alpha} = \sqrt{1 - (\sqrt{1-t^2})^2} = \sqrt{1 - (1-t^2)} = \sqrt{t^2} = t$, since $t \geq 0$. Since $\cos \alpha = t$ and $0 \leq \alpha \leq \frac{\pi}{2}$, we conclude that $\alpha = \cos^{-1} t$, as desired.

81. The side of the tank that lies in the xz -plane is bounded by the semicircle $x^2 + z^2 = 1$, $z \leq 0$, or $z = -\sqrt{1-x^2}$. The horizontal line that represents the water level of depth a meters, that is at $z = -1+a$, crosses this semicircle, that is the surface of the tank, at the points with $x = \pm\sqrt{1-(-1+a)^2} = \pm\sqrt{2a-a^2}$; see the figure below. So the volume of the water can be represented as the solid enclosed between $z = f_1(x, y) = -\sqrt{1-x^2}$ and $z = f_2(x, y) = -1+a$ over the region R in the xy -plane, that is a rectangle $-\sqrt{2a-a^2} \leq x \leq \sqrt{2a-a^2}$, $0 \leq y \leq 4$; and we can find its volume as the double integral

$$\iint_R [f_2(x, y) - f_1(x, y)] dA = \int_0^4 \left[\int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} (-1+a + \sqrt{1-x^2}) dx \right] dy.$$

Let I be the value of the integral in the brackets; we find it by integrating with respect to x . The integral in the brackets can be split into a sum of two integrals:

$$I = \int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} (-1+a + \sqrt{1-x^2}) dx = \int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} (-1+a) dx + \int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} \sqrt{1-x^2} dx.$$

The first integral can be evaluated directly as

$$\int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} (-1+a) dx = [(-1+a)x]_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} = (-1+a) \left[\sqrt{2a-a^2} - (-\sqrt{2a-a^2}) \right] = 2(a-1)\sqrt{2a-a^2}.$$

To evaluate the second integral, we will find an antiderivative using a substitution $x = \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = \cos \theta d\theta$. Also, $\sqrt{1-x^2} = \sqrt{1-\sin^2 \theta} = \sqrt{\cos^2 \theta} = \cos \theta$, and the integral becomes

$$\begin{aligned} \int \sqrt{1-x^2} dx &= \int \cos \theta \cdot \cos \theta d\theta = \int \cos^2 \theta d\theta \\ &= \int \frac{1}{2}(1 + \cos 2\theta) d\theta = \frac{1}{2} \left(\theta + \frac{1}{2} \sin 2\theta \right) = \frac{1}{2}(\theta + \sin \theta \cos \theta). \end{aligned}$$

To express this antiderivative in terms of x , we first observe that since $x = \sin \theta$, then $\theta = \sin^{-1}(x)$. Also, as shown above, $\cos \theta = \sqrt{1-x^2}$. So an antiderivative is

$$\int \sqrt{1-x^2} dx = \frac{1}{2}(\theta + \sin \theta \cos \theta) = \frac{1}{2} \left(\sin^{-1} x + x\sqrt{1-x^2} \right).$$

Going back to the integral $\int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} \sqrt{1-x^2} dx$, notice that the integrand is an even function and the interval of integration is symmetric about the origin, so by properties of definite integrals

$$\begin{aligned} \int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} \sqrt{1-x^2} dx &= 2 \int_0^{\sqrt{2a-a^2}} \sqrt{1-x^2} dx \\ &= 2 \left[\frac{1}{2} \left(\sin^{-1} x + x\sqrt{1-x^2} \right) \right]_0^{\sqrt{2a-a^2}} = \left[\sin^{-1} x + x\sqrt{1-x^2} \right]_0^{\sqrt{2a-a^2}} \\ &= \left(\sin^{-1} \sqrt{2a-a^2} + \sqrt{2a-a^2} \sqrt{1-(2a-a^2)} \right) - (\sin^{-1} 0 + 0) \\ &= \sin^{-1} \sqrt{2a-a^2} + (1-a)\sqrt{2a-a^2} - 0 = \sin^{-1} \sqrt{2a-a^2} + (1-a)\sqrt{2a-a^2}, \end{aligned}$$

where we simplified $\sqrt{1 - (2a - a^2)} = \sqrt{1 - 2a + a^2} = \sqrt{(1 - a)^2} = 1 - a$ since $a < 1$. So the integral in the brackets is

$$\begin{aligned} I &= \int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} (-1 + a + \sqrt{1-x^2}) dx = 2(a-1)\sqrt{2a-a^2} + \sin^{-1} \sqrt{2a-a^2} - (a-1)\sqrt{2a-a^2} \\ &= (a-1)\sqrt{2a-a^2} + \sin^{-1} \sqrt{2a-a^2}, \end{aligned}$$

and the volume of the liquid is

$$\begin{aligned} V_{\text{liquid}} &= \int_0^4 \left[\int_{-\sqrt{2a-a^2}}^{\sqrt{2a-a^2}} (-1 + a + \sqrt{1-x^2}) dx \right] dy = \int_0^4 I dy \\ &= I \cdot [y]_0^4 = I \cdot (4 - 0) = 4I = \boxed{4 \left[(a-1)\sqrt{2a-a^2} + \sin^{-1} \sqrt{2a-a^2} \right] \text{ m}^3}. \end{aligned}$$

82. Let R be the region in the xy -plane representing the shape of the valley, as shown in the figure in Problem 82. The right side of its V-shape (in the first quadrant) is a line segment through the points $(0,0)$ and $(100,150)$, therefore its slope is $m = \frac{150-0}{100-0} = \frac{3}{2}$, and its equation is $y = \frac{3}{2}x$ or $x = \frac{2}{3}y$; similarly, the equation of the other side (in the second quadrant) passing through $(0,0)$ and $(-100,150)$ is $y = -\frac{3}{2}x$ or $x = -\frac{2}{3}y$. So we can view R as a y -simple region: it is bounded by $x = -\frac{2}{3}y$ and $x = \frac{2}{3}y$, where $0 \leq y \leq 150$.

The surface of the water is at the level of $y = 150$ meters. Partition R into subrectangles of width Δx and height Δy ; assume that after disregarding subrectangles that do not lie entirely in R , we are left with N subrectangles, each of area $\Delta A = \Delta x \Delta y$. In each subrectangle choose an arbitrary point (u_k, v_k) , $k = 1, 2, \dots, N$. If Δy is small, then all points in the k th subrectangle lie at about the same height v_k from the bottom. The pressure due to the water at a depth of $d_k = 150 - v_k$ meters is $P_k = \rho g d_k = \rho g(150 - v_k)$ pascals, so the outward force acting on the k th subrectangle is $F_k = P_k \Delta A = \rho g(150 - v_k) \Delta A$ newtons, and the total force is approximately

$$F \approx \sum_{k=1}^N F_k = \sum_{k=1}^N \rho g(150 - v_k) \Delta A.$$

These are Riemann sums of a continuous function $f(x, y) = \rho g(150 - y)$; and as the number of subrectangles $N \rightarrow \infty$, these sums become better and better approximations to the force due to water

pressure, which can be represented, as the limit of Riemann sums, by the double integral

$$\begin{aligned}
 F &= \iint_R f(x, y) \, dA = \iint_R \rho g(150 - y) \, dA = \int_0^{150} \left[\int_{-2y/3}^{2y/3} \rho g(150 - y) \, dx \right] dy \\
 &= \int_0^{150} \rho g(150 - y) \left[\int_{-2y/3}^{2y/3} dx \right] dy = \int_0^{150} \rho g(150 - y) [x]_{-2y/3}^{2y/3} dy \\
 &= \int_0^{150} \rho g(150 - y) \left[\frac{2y}{3} - \left(-\frac{2y}{3} \right) \right] dy = \int_0^{150} \rho g(150 - y) \cdot \frac{4y}{3} dy \\
 &= \rho g \int_0^{150} \left(200y - \frac{4}{3}y^2 \right) dy = \rho g \left[100y^2 - \frac{4}{9}y^3 \right]_0^{150} = \rho g \left[\left(100 \cdot 150^2 - \frac{4}{9} \cdot 150^3 \right) - (0 - 0) \right] \\
 &= \rho g \cdot 750,000 = 1000 \cdot 9.8 \cdot 750,000 = \boxed{7,350,000,000 \text{ N}}.
 \end{aligned}$$

To convert this value to pounds we use the fact that $1 \text{ N} \approx 0.2248 \text{ lb}$, so

$$F = 7,350,000,000 \text{ N} \times 0.2248 \text{ lb/N} = \boxed{1,652,280,000 \text{ lb}}.$$

83. Answers will vary.

84. We begin by graphing the solid tetrahedron S enclosed by the coordinate planes and the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ (where $a, b, c > 0$). This solid lies under the graph of $z = f(x, y) = c \left(1 - \frac{x}{a} - \frac{y}{b} \right)$ and above the region R in the xy -plane, which is the triangular region in the xy -plane bounded by the coordinate axes and the line $\frac{x}{a} + \frac{y}{b} = 1$. Notice that R is an x -simple region: it is bounded by $y = 0$ and $y = b \left(1 - \frac{x}{a} \right)$, where $0 \leq x \leq a$. See the figures below. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) \, dA = \int_0^a \left[\int_0^{b(1-x/a)} c \left(1 - \frac{x}{a} - \frac{y}{b} \right) dy \right] dx \\
 &= \int_0^a c \left[\left(1 - \frac{x}{a} \right) y - \frac{1}{2b} y^2 \right]_0^{b(1-x/a)} dx = \int_0^a c \left[\left(1 - \frac{x}{a} \right) \cdot b \left(1 - \frac{x}{a} \right) - \frac{1}{2b} b^2 \left(1 - \frac{x}{a} \right)^2 \right] dx \\
 &= \int_0^a c \left[b \left(1 - \frac{x}{a} \right)^2 - \frac{b}{2} \left(1 - \frac{x}{a} \right)^2 \right] dx = \int_0^a c \cdot \frac{b}{2} \left(1 - \frac{x}{a} \right)^2 dx = \frac{bc}{2} \int_0^a \left(1 - \frac{x}{a} \right)^2 dx.
 \end{aligned}$$

In this integral we make a substitution $u = 1 - \frac{x}{a}$; then $du = -\frac{dx}{a}$, so $dx = -adu$. We also change the limits of integration: if $x = 0$, then $u = 1 - \frac{0}{a} = 1$; if $x = a$, then $u = 1 - \frac{a}{a} = 0$. So

$$\begin{aligned}
 V &= \frac{bc}{2} \int_0^a \left(1 - \frac{x}{a} \right)^2 dx = \frac{bc}{2} \int_1^0 u^2 (-adu) = -\frac{abc}{2} \int_1^0 u^2 du \\
 &= \frac{abc}{2} \int_0^1 u^2 du = \frac{abc}{2} \left[\frac{u^3}{3} \right]_0^1 = \frac{abc}{6} [u^3]_0^1 = \frac{abc}{6} \cdot (1 - 0) = \boxed{\frac{abc}{6} \text{ cubic units}}.
 \end{aligned}$$

85. We begin by graphing the region R enclosed by the parabolas $y = 4 - x^2$ and $y = x^2$ to the right of the y -axis; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = x^2$ to $y = 4 - x^2$, $0 \leq x \leq \sqrt{2}$. Then

$$\begin{aligned}
 \iint_R xy \, dA &= \int_0^{\sqrt{2}} \left[\int_{x^2}^{4-x^2} xy \, dy \right] dx = \int_0^{\sqrt{2}} x \left[\int_{x^2}^{4-x^2} y \, dy \right] dx = \int_0^{\sqrt{2}} x \left[\frac{y^2}{2} \right]_{x^2}^{4-x^2} dx \\
 &= \int_0^{\sqrt{2}} x \left[\frac{(4-x^2)^2}{2} - \frac{(x^2)^2}{2} \right] dx = \int_0^{\sqrt{2}} x \left(\frac{16-8x^2+x^4}{2} - \frac{x^4}{2} \right) dx \\
 &= \int_0^{\sqrt{2}} x(8-4x^2) \, dx = \int_0^{\sqrt{2}} (8x-4x^3) \, dx = [4x^2 - x^4]_0^{\sqrt{2}} \\
 &= \left[4(\sqrt{2})^2 - (\sqrt{2})^4 \right] - (0-0) = 8-4 = \boxed{4}.
 \end{aligned}$$

86. We begin by graphing the region R enclosed by the parabolas $x = 4 - y^2$ and $x = y^2$ above the x -axis; see the figure below. Observe that R is a closed bounded region, that is y -simple: x varies from $x = y^2$ to $x = 4 - y^2$, $0 \leq y \leq \sqrt{2}$. Then

$$\begin{aligned}
 \iint_R xy \, dA &= \int_0^{\sqrt{2}} \left[\int_{y^2}^{4-y^2} xy \, dx \right] dy = \int_0^{\sqrt{2}} y \left[\int_{y^2}^{4-y^2} x \, dx \right] dy = \int_0^{\sqrt{2}} y \left[\frac{x^2}{2} \right]_{y^2}^{4-y^2} dy \\
 &= \int_0^{\sqrt{2}} y \left[\frac{(4-y^2)^2}{2} - \frac{(y^2)^2}{2} \right] dy = \int_0^{\sqrt{2}} y \left(\frac{16-8y^2+y^4}{2} - \frac{y^4}{2} \right) dy \\
 &= \int_0^{\sqrt{2}} y(8-4y^2) \, dy = \int_0^{\sqrt{2}} (8y-4y^3) \, dy = [4y^2 - y^4]_0^{\sqrt{2}} \\
 &= \left[4(\sqrt{2})^2 - (\sqrt{2})^4 \right] - (0-0) = 8-4 = \boxed{4}.
 \end{aligned}$$

87. We begin by graphing the region R enclosed by the lines $y = x$, $x = 1$, and $y = 0$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = 0$ to $y = x$, $0 \leq x \leq 1$.

Then

$$\begin{aligned}\iint_R e^{\sqrt{x}} dA &= \int_0^1 \left[\int_0^x e^{\sqrt{x}} dy \right] dx = \int_0^1 e^{\sqrt{x}} \left[\int_0^x dy \right] dx \\ &= \int_0^1 e^{\sqrt{x}} [y]_0^x dx = \int_0^1 e^{\sqrt{x}} \cdot (x-0) dx = \int_0^1 x e^{\sqrt{x}} dx.\end{aligned}$$

In this integral we make a substitution $x = t^2$, so that $\sqrt{x} = t$; then $dx = 2t dt$. We also change the limits of integration: if $x = 0$, then $t = \sqrt{0} = 0$; if $x = 1$, then $t = \sqrt{1} = 1$. So

$$\int_0^1 x e^{\sqrt{x}} dx = \int_0^1 t^2 e^t \cdot 2t dt = \int_0^1 2t^3 e^t dt.$$

We evaluate this integral by applying integration by parts three times (because the integrand is a polynomial of degree 3 times e^t). First time, we set $u = 2t^3$ and $dv = e^t dt$, then $du = 6t^2 dt$ and $v = \int e^t dt = e^t$; then

$$\int_0^1 2t^3 e^t dt = [2t^3 \cdot e^t]_0^1 - \int_0^1 e^t \cdot 6t^2 dt = (2e - 0) - \int_0^1 6t^2 e^t dt = 2e - \int_0^1 6t^2 e^t dt.$$

Next, we set $u = 6t^2$ and $dv = e^t dt$, then $du = 12t dt$ and $v = \int e^t dt = e^t$; then

$$\begin{aligned}2e - \int_0^1 6t^2 e^t dt &= 2e - \left([6t^2 \cdot e^t]_0^1 - \int_0^1 e^t \cdot 12t dt \right) \\ &= 2e - \left((6e - 0) - \int_0^1 12te^t dt \right) = -4e + \int_0^1 12te^t dt.\end{aligned}$$

And finally, we set $u = 12t$ and $dv = e^t dt$, then $du = 12 dt$ and $v = \int e^t dt = e^t$; then

$$\begin{aligned}-4e + \int_0^1 12te^t dt &= -4e + \left([12t \cdot e^t]_0^1 - \int_0^1 e^t \cdot 12 dt \right) = -4e + \left((12e - 0) - \int_0^1 12e^t dt \right) \\ &= 8e - \int_0^1 12e^t dt = 8e - 12 [e^t]_0^1 = 8e - 12(e - 1) = \boxed{12 - 4e}.\end{aligned}$$

88. (a) Assume $0 \leq a \leq b$, where a and b are constants. Then the region R defined by $0 \leq a \leq y \leq b$, $0 \leq a \leq x \leq y$ is the triangular region shown in the figure.

- (b) Observe that R is a closed bounded region, that is x -simple: y varies from $y = x$ to $y = b$, $a \leq x \leq b$. Then for a function $f(x)$ continuous on R ,

$$\begin{aligned} \iint_R f(x) dA &= \int_a^b \left[\int_x^b f(x) dy \right] dx = \int_a^b f(x) \left[\int_x^b dy \right] dx \\ &= \int_a^b f(x) [y]_x^b dx = \int_a^b f(x) \cdot (b - x) dx = \int_a^b (b - x)f(x) dx. \end{aligned}$$

89. Let f and g be integrable function on a region R in the xy -plane, and assume that $f(x, y) \leq g(x, y)$ on R . Let $h(x, y) = g(x, y) - f(x, y)$ be a function of two variables defined on R . Since $f(x, y) \leq g(x, y)$ on R , it follows that $h(x, y) \geq 0$ on R . Then the double integral $\iint_R h(x, y) dA$ equals the volume under the surface $z = h(x, y)$ over the region R , and so it is a nonnegative quantity. Now, using properties of double integrals,

$$0 \leq \iint_R h(x, y) dA = \iint_R [g(x, y) - f(x, y)] dA = \iint_R g(x, y) dA - \iint_R f(x, y) dA.$$

Since $\iint_R g(x, y) dA - \iint_R f(x, y) dA \geq 0$, it follows that $\iint_R f(x, y) dA \leq \iint_R g(x, y) dA$.

Challenge Problem

90. We begin by graphing the solid S under the elliptic paraboloid $z = f(x, y) = 8 - 2x^2 - y^2$ and above the first quadrant in the xy -plane; see figure (a). Its base in the xy -plane is the region R bounded by the ellipse $2x^2 + y^2 = 8$ and the coordinate axes in the first quadrant, as shown on figure (b). Observe that R is an x -simple region: y varies from $y = 0$ to $y = \sqrt{8 - 2x^2}$, where $0 \leq x \leq 2$. So the volume V of the solid S is

$$\begin{aligned} V &= \iint_R f(x, y) dA = \int_0^2 \left[\int_0^{\sqrt{8-2x^2}} (8 - 2x^2 - y^2) dy \right] dx = \int_0^2 \left[(8 - 2x^2)y - \frac{1}{3}y^3 \right]_0^{\sqrt{8-2x^2}} dx \\ &= \int_0^2 \left[(8 - 2x^2)\sqrt{8 - 2x^2} - \frac{1}{3}(\sqrt{8 - 2x^2})^3 \right] dx = \int_0^2 \frac{2}{3}(\sqrt{8 - 2x^2})^3 dx. \end{aligned}$$

In this integral, we make a substitution $x = 2 \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = 2 \cos \theta d\theta$. Also, $\sqrt{8 - 2x^2} = \sqrt{8 - 2(2 \sin \theta)^2} = \sqrt{8 - 8 \sin^2 \theta} = \sqrt{8(1 - \sin^2 \theta)} = \sqrt{8 \cos^2 \theta} = 2\sqrt{2} \cos \theta$. The limits of integration can be recalculated as follows: if $x = 0$, then $\sin \theta = \frac{0}{2} = 0$ and $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ imply that

$\theta = 0$; if $x = 2$, then $\sin \theta = \frac{2}{2} = 1$ and $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ imply that $\theta = \frac{\pi}{2}$. So the integral becomes

$$\begin{aligned} \int_0^2 \frac{2}{3} \left(\sqrt{8-2x^2} \right)^3 dx &= \int_0^{\pi/2} \frac{2}{3} (2\sqrt{2} \cos \theta)^3 \cdot 2 \cos \theta d\theta \\ &= \int_0^{\pi/2} \frac{2}{3} \cdot 16\sqrt{2} \cos^3 \theta \cdot 2 \cos \theta d\theta = \frac{64\sqrt{2}}{3} \int_0^{\pi/2} \cos^4 \theta d\theta. \end{aligned}$$

To find the value of this integral, we can use Wallis's formula given in Section 7.1, Problem 69. Applying Wallis's formula with $n = 4$, we obtain

$$V = \frac{64\sqrt{2}}{3} \int_0^{\pi/2} \cos^4 \theta d\theta = \frac{64\sqrt{2}}{3} \cdot \frac{3 \cdot 1}{4 \cdot 2} \cdot \frac{\pi}{2} = \boxed{4\sqrt{2}\pi \text{ cubic units}}.$$

(a)

(b)

14.3 Double Integrals Using Polar Coordinates

Concepts and Vocabulary

1. $f(x, y) = \sqrt{4x^2 + 4y^2} = \sqrt{4(x^2 + y^2)} = \sqrt{4r^2} = 2r$, assuming $r \geq 0$, so $\boxed{f(r, \theta) = 2r}$.
2. In polar coordinates, the differential of the area is $dA = \boxed{r \, dr \, d\theta}$.
3. **False**. If $f(x, y) \geq 0$ is continuous on a closed bounded region R , the volume under the surface $z = f(x, y)$ over R can be found as $\iint_R f(x, y) \, dA$. Since in polar coordinates the differential of the area is $dA = r \, dr \, d\theta$, then $\iint_R f(x, y) \, dA = \iint_R f(r \cos \theta, r \sin \theta) r \, dr \, d\theta \neq \iint_R f(r \cos \theta, r \sin \theta) \, dr \, d\theta$.
4. **True**. The area of a closed bounded region R can be found as $A = \iint_R dA = \iint_R r \, dr \, d\theta$.

Skill Building

5. The region R given in the figure in Problem 5 is bounded by the circle of radius 2 centered at the origin. In polar coordinates, this region R is given as $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$. Then

$$\iint_R f(x, y) \, dA = \boxed{\int_0^{2\pi} \int_0^2 f(r \cos \theta, r \sin \theta) r \, dr \, d\theta}.$$

6. The region R given in the figure in Problem 6 is half of the disk of radius 3 centered at the origin lying to the right of the y -axis. In polar coordinates, this region R is given as $0 \leq r \leq 3$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then

$$\iint_R f(x, y) \, dA = \boxed{\int_{-\pi/2}^{\pi/2} \int_0^3 f(r \cos \theta, r \sin \theta) r \, dr \, d\theta}.$$

7. The region R given in the figure in Problem 7 is the annular region contained between the concentric circles of radii 1 and 3 centered at the origin. In polar coordinates, this region R is given as $1 \leq r \leq 3$, $0 \leq \theta \leq 2\pi$. Then

$$\iint_R f(x, y) \, dA = \boxed{\int_0^{2\pi} \int_1^3 f(r \cos \theta, r \sin \theta) r \, dr \, d\theta}.$$

8. The region R given in the figure in Problem 8 is part of the annular region contained between the concentric circles of radii 1 and 2 centered at the origin lying in the first quadrant. In polar coordinates, this region R is given as $1 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$. Then

$$\iint_R f(x, y) \, dA = \boxed{\int_0^{\pi/2} \int_1^2 f(r \cos \theta, r \sin \theta) r \, dr \, d\theta}.$$

9. The region R enclosed by $x^2 + y^2 = 9$, $x \geq 0$, and $y \geq 0$ is a quarter of the disk of radius 3 centered at the origin lying in the first quadrant, as shown in the figure below. In polar coordinates, this region R is given as $0 \leq r \leq 3$, $0 \leq \theta \leq \frac{\pi}{2}$. Then

$$\iint_R (x + y) \, dA = \int_0^{\pi/2} \int_0^3 (r \cos \theta + r \sin \theta) r \, dr \, d\theta = \boxed{\int_0^{\pi/2} \int_0^3 r^2 (\cos \theta + \sin \theta) \, dr \, d\theta}.$$

10. The region R enclosed by $y = \sqrt{1 - x^2}$ and the lines $y = x$ and $y = -x$ is part of the disk of radius 1 centered at the origin, as shown in the figure below. In polar coordinates, this region R is given as $0 \leq r \leq 1$, $\frac{\pi}{4} \leq \theta \leq \frac{3\pi}{4}$. Also, the integrand can be simplified as $x^2 + y^2 = r^2$. Then

$$\iint_R (x^2 + y^2) dA = \int_{\pi/4}^{3\pi/4} \int_0^1 r^2 r dr d\theta = \boxed{\int_{\pi/4}^{3\pi/4} \int_0^1 r^3 dr d\theta}.$$

11. The region R enclosed by $x = \sqrt{4 - y^2}$, the positive x -axis, and the line $y = x$ is part of the disk of radius 2 centered at the origin, as shown in the figure below. In polar coordinates, this region R is given as $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{4}$. Then

$$\iint_R x dA = \int_0^{\pi/4} \int_0^2 r \cos \theta r dr d\theta = \boxed{\int_0^{\pi/4} \int_0^2 r^2 \cos \theta dr d\theta}.$$

12. The region R enclosed by $y = \sqrt{16 - x^2}$ in the first quadrant is quarter of the disk of radius 4 centered at the origin, as shown in the figure below. In polar coordinates, this region R is given as $0 \leq r \leq 4$,

$0 \leq \theta \leq \frac{\pi}{2}$. Then

$$\iint_R y \, dA = \int_0^{\pi/2} \int_0^4 r \sin \theta \, dr \, d\theta = \boxed{\int_0^{\pi/2} \int_0^4 r^2 \sin \theta \, dr \, d\theta}.$$

13. The region R enclosed by $x^2 + y^2 = 1$ and $x^2 + y^2 = 4$ is the annular region contained between the concentric circles of radii 1 and 2 centered at the origin, as shown in the figure below. In polar coordinates, this region R is given as $1 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$. Then

$$\iint_R (x + y^2) \, dA = \int_0^{2\pi} \int_1^2 (r \cos \theta + r^2 \sin^2 \theta) r \, dr \, d\theta = \boxed{\int_0^{2\pi} \int_1^2 (r^2 \cos \theta + r^3 \sin^2 \theta) \, dr \, d\theta}.$$

14. The region R enclosed by $x^2 + y^2 = \frac{1}{4}$ and $x^2 + y^2 = 5$ is the annular region contained between the concentric circles of radii $\frac{1}{2}$ and $\sqrt{5}$ centered at the origin, as shown in the figure below. In polar coordinates, this region R is given as $\frac{1}{2} \leq r \leq \sqrt{5}$, $0 \leq \theta \leq 2\pi$. Also, the integrand can be simplified as $\sqrt{x^2 + y^2} = \sqrt{r^2} = r$. Then

$$\iint_R \sqrt{x^2 + y^2} \, dA = \int_0^{2\pi} \int_{1/2}^{\sqrt{5}} r \, r \, dr \, d\theta = \boxed{\int_0^{2\pi} \int_{1/2}^{\sqrt{5}} r^2 \, dr \, d\theta}.$$

15. To find this iterated integral, we first integrate partially with respect to r .

$$\begin{aligned} \int_0^{\pi/4} \int_0^{4 \sin \theta} r \cos \theta \, dr \, d\theta &= \int_0^{\pi/4} \cos \theta \left[\int_0^{4 \sin \theta} r \, dr \right] d\theta \\ &= \int_0^{\pi/4} \cos \theta \left[\frac{r^2}{2} \right]_0^{4 \sin \theta} d\theta = \int_0^{\pi/4} \cos \theta \left[\frac{(4 \sin \theta)^2}{2} - 0 \right] d\theta \\ &= \int_0^{\pi/4} \cos \theta \cdot 8 \sin^2 \theta \, d\theta = 8 \int_0^{\pi/4} \sin^2 \theta \cos \theta \, d\theta. \end{aligned}$$

In this integral we make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$. We also change the limits of integration: if $\theta = 0$, then $u = \sin 0 = 0$; if $\theta = \frac{\pi}{4}$, then $u = \sin \frac{\pi}{4} = \frac{\sqrt{2}}{2}$. So

$$8 \int_0^{\pi/4} \sin^2 \theta \cos \theta \, d\theta = 8 \int_0^{\sqrt{2}/2} u^2 \, du = 8 \left[\frac{u^3}{3} \right]_0^{\sqrt{2}/2} = \frac{8}{3} \left[\left(\frac{\sqrt{2}}{2} \right)^3 - 0 \right] = \frac{8}{3} \cdot \frac{2\sqrt{2}}{8} = \boxed{\frac{2\sqrt{2}}{3}}.$$

16. To find this iterated integral, we first integrate partially with respect to r .

$$\begin{aligned} \int_0^{5\pi/3} \int_0^{2 \cos \theta} r \sin \theta \, dr \, d\theta &= \int_0^{5\pi/3} \sin \theta \left[\int_0^{2 \cos \theta} r \, dr \right] d\theta \\ &= \int_0^{5\pi/3} \sin \theta \left[\frac{r^2}{2} \right]_0^{2 \cos \theta} d\theta = \int_0^{5\pi/3} \sin \theta \left[\frac{(2 \cos \theta)^2}{2} - 0 \right] d\theta \\ &= \int_0^{5\pi/3} \sin \theta \cdot 2 \cos^2 \theta \, d\theta = 2 \int_0^{5\pi/3} \cos^2 \theta \sin \theta \, d\theta. \end{aligned}$$

In this integral we make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = 0$, then $u = \cos 0 = 1$; if $\theta = \frac{5\pi}{3}$, then $u = \cos \frac{5\pi}{3} = \frac{1}{2}$. So

$$\begin{aligned} 2 \int_0^{5\pi/3} \cos^2 \theta \sin \theta \, d\theta &= 2 \int_1^{1/2} u^2 (-du) = -2 \int_1^{1/2} u^2 \, du \\ &= 2 \int_{1/2}^1 u^2 \, du = 2 \left[\frac{u^3}{3} \right]_{1/2}^1 = \frac{2}{3} \left[1^3 - \left(\frac{1}{2} \right)^3 \right] = \frac{2}{3} \cdot \frac{7}{8} = \boxed{\frac{7}{12}}. \end{aligned}$$

17. To find this iterated integral, we first integrate partially with respect to θ .

$$\begin{aligned} \int_0^{\pi/2} \int_0^{\pi/3} r \, d\theta \, dr &= \int_0^{\pi/2} r \left[\int_0^{\pi/3} d\theta \right] dr = \int_0^{\pi/2} r [\theta]_0^{\pi/3} dr = \int_0^{\pi/2} r \left[\frac{\pi}{3} - 0 \right] dr \\ &= \frac{\pi}{3} \int_0^{\pi/2} r \, dr = \frac{\pi}{3} \left[\frac{r^2}{2} \right]_0^{\pi/2} = \frac{\pi}{6} \left[\left(\frac{\pi}{2} \right)^2 - 0 \right] = \frac{\pi}{6} \cdot \frac{\pi^2}{4} = \boxed{\frac{\pi^3}{24}}. \end{aligned}$$

18. To find this iterated integral, we first integrate partially with respect to r .

$$\begin{aligned}
 \int_0^{\pi/3} \int_0^{\sin \theta} r \, dr \, d\theta &= \int_0^{\pi/3} \left[\frac{r^2}{2} \right]_0^{\sin \theta} d\theta = \int_0^{\pi/3} \left[\frac{(\sin \theta)^2}{2} - 0 \right] d\theta = \frac{1}{2} \int_0^{\pi/3} \sin^2 \theta \, d\theta \\
 &= \frac{1}{2} \int_0^{\pi/3} \frac{1}{2} (1 - \cos(2\theta)) \, d\theta = \frac{1}{4} \int_0^{\pi/3} (1 - \cos(2\theta)) \, d\theta = \frac{1}{4} \left[\theta - \frac{1}{2} \sin(2\theta) \right]_0^{\pi/3} \\
 &= \left[\frac{1}{4} \theta - \frac{1}{8} \sin(2\theta) \right]_0^{\pi/3} = \left(\frac{1}{4} \cdot \frac{\pi}{3} - \frac{1}{8} \sin \frac{2\pi}{3} \right) - \left(\frac{1}{4} \cdot 0 - \frac{1}{8} \sin 0 \right) \\
 &= \frac{\pi}{12} - \frac{1}{8} \cdot \frac{\sqrt{3}}{2} - 0 = \boxed{\frac{\pi}{12} - \frac{\sqrt{3}}{16}}.
 \end{aligned}$$

19. To find this iterated integral, we first integrate partially with respect to r .

$$\begin{aligned}
 \int_0^{\pi/4} \int_0^{\cos \theta} r \, dr \, d\theta &= \int_0^{\pi/4} \left[\frac{r^2}{2} \right]_0^{\cos \theta} d\theta = \int_0^{\pi/4} \left[\frac{(\cos \theta)^2}{2} - 0 \right] d\theta = \frac{1}{2} \int_0^{\pi/4} \cos^2 \theta \, d\theta \\
 &= \frac{1}{2} \int_0^{\pi/4} \frac{1}{2} (1 + \cos(2\theta)) \, d\theta = \frac{1}{4} \int_0^{\pi/4} (1 + \cos(2\theta)) \, d\theta = \frac{1}{4} \left[\theta + \frac{1}{2} \sin(2\theta) \right]_0^{\pi/4} \\
 &= \left[\frac{1}{4} \theta + \frac{1}{8} \sin(2\theta) \right]_0^{\pi/4} = \left(\frac{1}{4} \cdot \frac{\pi}{4} + \frac{1}{8} \sin \frac{\pi}{2} \right) - \left(\frac{1}{4} \cdot 0 + \frac{1}{8} \sin 0 \right) \\
 &= \frac{\pi}{16} + \frac{1}{8} \cdot 1 - 0 = \frac{\pi}{16} + \frac{1}{8} = \boxed{\frac{\pi + 2}{16}}.
 \end{aligned}$$

20. To find this iterated integral, we first integrate partially with respect to θ .

$$\begin{aligned}
 \int_0^4 \int_{-\pi/4}^{\pi/4} r \cos \theta \, d\theta \, dr &= \int_0^4 r \left[\int_{-\pi/4}^{\pi/4} \cos \theta \, d\theta \right] dr = \int_0^4 r [\sin \theta]_{-\pi/4}^{\pi/4} dr \\
 &= \int_0^4 r \left[\sin \frac{\pi}{4} - \sin \left(-\frac{\pi}{4} \right) \right] dr = \int_0^4 r \left[\frac{\sqrt{2}}{2} - \left(-\frac{\sqrt{2}}{2} \right) \right] dr \\
 &= \sqrt{2} \int_0^4 r \, dr = \sqrt{2} \left[\frac{r^2}{2} \right]_0^4 = \sqrt{2} \cdot (8 - 0) = \boxed{8\sqrt{2}}.
 \end{aligned}$$

21. To find this iterated integral, we first integrate partially with respect to θ .

$$\begin{aligned}
 \int_0^2 \int_{-\pi/3}^{5\pi/3} r \sin \theta \, d\theta \, dr &= \int_0^2 r \left[\int_{-\pi/3}^{5\pi/3} \sin \theta \, d\theta \right] dr = \int_0^2 r [-\cos \theta]_{-\pi/3}^{5\pi/3} dr \\
 &= \int_0^2 r \left[-\cos \frac{5\pi}{3} + \cos \left(-\frac{\pi}{3} \right) \right] dr = \int_0^2 r \left(-\frac{1}{2} + \frac{1}{2} \right) dr = \int_0^2 0 \, dr = \boxed{0}.
 \end{aligned}$$

22. To find this iterated integral, we first integrate partially with respect to θ .

$$\begin{aligned}
 \int_0^{\pi} \int_0^{\pi/4} r \, d\theta \, dr &= \int_0^{\pi} r \left[\int_0^{\pi/4} d\theta \right] dr = \int_0^{\pi} r [\theta]_0^{\pi/4} dr \\
 &= \int_0^{\pi} r \left(\frac{\pi}{4} - 0 \right) dr = \frac{\pi}{4} \int_0^{\pi} r \, dr = \frac{\pi}{4} \left[\frac{r^2}{2} \right]_0^{\pi} = \frac{\pi}{4} \left(\frac{\pi^2}{2} - 0 \right) = \boxed{\frac{\pi^3}{8}}.
 \end{aligned}$$

23. The region R described in polar coordinates as $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$ is a quarter of the disk of radius 2 centered at the origin lying in the first quadrant, as shown in the figure below. To find the

given double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned}
 \iint_R 3 \sin \theta \, dA &= \int_0^{\pi/2} \int_0^2 3 \sin \theta \cdot r \, dr \, d\theta = \int_0^{\pi/2} 3 \sin \theta \left[\int_0^2 r \, dr \right] d\theta \\
 &= \int_0^{\pi/2} 3 \sin \theta \left[\frac{r^2}{2} \right]_0^2 d\theta = \int_0^{\pi/2} 3 \sin \theta \cdot (2 - 0) \, d\theta = 6 \int_0^{\pi/2} \sin \theta \, d\theta \\
 &= 6[-\cos \theta]_0^{\pi/2} = 6 \left(-\cos \frac{\pi}{2} + \cos 0 \right) = 6 \cdot (-0 + 1) = \boxed{6}.
 \end{aligned}$$

24. The region R described in polar coordinates as $0 \leq r \leq 3$, $0 \leq \theta \leq \frac{\pi}{2}$ is a quarter of the disk of radius 3 centered at the origin lying in the first quadrant, as shown in the figure below. To find the given double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned}
 \iint_R 4 \cos \theta \, dA &= \int_0^{\pi/2} \int_0^3 4 \cos \theta \cdot r \, dr \, d\theta = \int_0^{\pi/2} 4 \cos \theta \left[\int_0^3 r \, dr \right] d\theta \\
 &= \int_0^{\pi/2} 4 \cos \theta \left[\frac{r^2}{2} \right]_0^3 d\theta = \int_0^{\pi/2} 4 \cos \theta \cdot \left(\frac{9}{2} - 0 \right) d\theta = 18 \int_0^{\pi/2} \cos \theta \, d\theta \\
 &= 18[\sin \theta]_0^{\pi/2} = 18 \left(\sin \frac{\pi}{2} - \sin 0 \right) = 18 \cdot (1 - 0) = \boxed{18}.
 \end{aligned}$$

25. The region R described in polar coordinates as $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$ is a quarter of the disk of radius 1 centered at the origin lying in the first quadrant, as shown in the figure below. To find the

given double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned}
 \iint_R 2r \sin \theta \, dA &= \int_0^{\pi/2} \int_0^1 2r \sin \theta \cdot r \, dr \, d\theta = \int_0^{\pi/2} 2 \sin \theta \left[\int_0^1 r^2 \, dr \right] d\theta \\
 &= \int_0^{\pi/2} 2 \sin \theta \left[\frac{r^3}{3} \right]_0^1 d\theta = \int_0^{\pi/2} 2 \sin \theta \cdot \left(\frac{1}{3} - 0 \right) d\theta = \frac{2}{3} \int_0^{\pi/2} \sin \theta \, d\theta \\
 &= \frac{2}{3} [-\cos \theta]_0^{\pi/2} = \frac{2}{3} \left(-\cos \frac{\pi}{2} + \cos 0 \right) = \frac{2}{3} \cdot (-0 + 1) = \boxed{\frac{2}{3}}.
 \end{aligned}$$

26. The region R described in polar coordinates as $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{4}$ is part of the disk of radius 2 centered at the origin lying in the first quadrant, as shown in the figure below. To find the given double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned}
 \iint_R 3r \cos \theta \, dA &= \int_0^{\pi/4} \int_0^2 3r \cos \theta \cdot r \, dr \, d\theta = \int_0^{\pi/4} 3 \cos \theta \left[\int_0^2 r^2 \, dr \right] d\theta \\
 &= \int_0^{\pi/4} 3 \cos \theta \left[\frac{r^3}{3} \right]_0^2 d\theta = \int_0^{\pi/4} 3 \cos \theta \cdot \left(\frac{8}{3} - 0 \right) d\theta = 8 \int_0^{\pi/4} \cos \theta \, d\theta \\
 &= 8 [\sin \theta]_0^{\pi/4} = 8 \left(\sin \frac{\pi}{4} - \sin 0 \right) = 8 \cdot \left(\frac{\sqrt{2}}{2} - 0 \right) = \boxed{4\sqrt{2}}.
 \end{aligned}$$

27. The region R described in polar coordinates as $0 \leq r \leq 2$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ is half of the disk of radius 2 centered at the origin lying to the right of the y -axis, as shown in the figure below. To find the given

double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned}
 \iint_R 3r^2 \sin \theta \, dA &= \int_{-\pi/2}^{\pi/2} \int_0^2 3r^2 \sin \theta \cdot r \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} 3 \sin \theta \left[\int_0^2 r^3 \, dr \right] d\theta \\
 &= \int_{-\pi/2}^{\pi/2} 3 \sin \theta \left[\frac{r^4}{4} \right]_0^2 d\theta = \int_{-\pi/2}^{\pi/2} 3 \sin \theta \cdot (4 - 0) \, d\theta = 12 \int_{-\pi/2}^{\pi/2} \sin \theta \, d\theta \\
 &= 12[-\cos \theta]_{-\pi/2}^{\pi/2} = 12 \left[-\cos \frac{\pi}{2} + \cos \left(-\frac{\pi}{2} \right) \right] = 12 \cdot (-0 + 0) = \boxed{0}.
 \end{aligned}$$

28. The region R described in polar coordinates as $0 \leq r \leq 4$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ is half of the disk of radius 4 centered at the origin lying to the right of the y -axis, as shown in the figure below. To find the given double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned}
 \iint_R 2r^2 \cos \theta \, dA &= \int_{-\pi/2}^{\pi/2} \int_0^4 2r^2 \cos \theta \cdot r \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} 2 \cos \theta \left[\int_0^4 r^3 \, dr \right] d\theta \\
 &= \int_{-\pi/2}^{\pi/2} 2 \cos \theta \left[\frac{r^4}{4} \right]_0^4 d\theta = \int_{-\pi/2}^{\pi/2} 2 \cos \theta \cdot (64 - 0) \, d\theta = 128 \int_{-\pi/2}^{\pi/2} \cos \theta \, d\theta \\
 &= 128[\sin \theta]_{-\pi/2}^{\pi/2} = 128 \left[\sin \frac{\pi}{2} - \sin \left(-\frac{\pi}{2} \right) \right] = 128 \cdot [1 - (-1)] = \boxed{256}.
 \end{aligned}$$

29. The region R associated with the integral $\int_0^1 \int_0^{\sqrt{1-x^2}} dy \, dx$ is enclosed between $y = 0$ and $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. This is the first-quadrant quarter of the disk of radius 1 centered at the origin, as

shown in the figure below. In polar coordinates R is given by $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$. Then

$$\begin{aligned} \int_0^1 \int_0^{\sqrt{1-x^2}} dy dx &= \iint_R dA = \int_0^{\pi/2} \int_0^1 r dr d\theta = \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_0^1 d\theta \\ &= \int_0^{\pi/2} \left(\frac{1}{2} - 0 \right) d\theta = \frac{1}{2} \int_0^{\pi/2} d\theta = \frac{1}{2} [\theta]_0^{\pi/2} = \frac{1}{2} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi}{4}}. \end{aligned}$$

30. The region R associated with the integral $\int_0^3 \int_0^y \sqrt{x^2 + y^2} dx dy$ is enclosed between $x = 0$ and $x = y$, where $0 \leq y \leq 3$. This is a triangular region shown in the figure below. In polar coordinates, it can be viewed as bounded, between the rays $\theta = \frac{\pi}{4}$ and $\theta = \frac{\pi}{2}$, by the graph of $y = 3$ or $r \sin \theta = 3$, so that $r = \frac{3}{\sin \theta} = 3 \csc \theta$. So in polar coordinates R is given by $0 \leq r \leq 3 \csc \theta$, $\frac{\pi}{4} \leq \theta \leq \frac{\pi}{2}$. Also, the integrand can be simplified as $\sqrt{x^2 + y^2} = \sqrt{r^2} = r$. Then

$$\begin{aligned} \int_0^3 \int_0^y \sqrt{x^2 + y^2} dx dy &= \iint_R \sqrt{x^2 + y^2} dA = \int_{\pi/4}^{\pi/2} \int_0^{3 \csc \theta} r \cdot r dr d\theta = \int_{\pi/4}^{\pi/2} \int_0^{3 \csc \theta} r^2 dr d\theta \\ &= \int_{\pi/4}^{\pi/2} \left[\frac{r^3}{3} \right]_0^{3 \csc \theta} d\theta = \int_{\pi/4}^{\pi/2} (9 \csc^3 \theta - 0) d\theta = 9 \int_{\pi/4}^{\pi/2} \csc^3 \theta d\theta. \end{aligned}$$

To evaluate this integral, we find an antiderivative of $\csc^3 \theta = \csc \theta \csc^2 \theta$ using the method of integration by parts: let $u = \csc \theta$ and $dv = \csc^2 \theta d\theta$; then $du = -\cot \theta \csc \theta d\theta$ and $v = \int \csc^2 \theta d\theta = -\cot \theta$. Then

$$\begin{aligned} \int \csc^3 \theta d\theta &= \int \csc \theta \csc^2 \theta d\theta = \csc \theta \cdot (-\cot \theta) - \int (-\cot \theta) \cdot (-\cot \theta \csc \theta d\theta) \\ &= -\cot \theta \csc \theta - \int \csc \theta \cot^2 \theta d\theta = -\cot \theta \csc \theta - \int \csc \theta (\csc^2 \theta - 1) d\theta \\ &= -\cot \theta \csc \theta - \int \csc^3 \theta d\theta + \int \csc \theta d\theta = -\cot \theta \csc \theta - \int \csc^3 \theta d\theta + \ln |\cot \theta - \csc \theta|. \end{aligned}$$

This relation allows us to solve for the desired antiderivative:

$$\begin{aligned} \int \csc^3 \theta d\theta &= -\cot \theta \csc \theta - \int \csc^3 \theta d\theta + \ln |\cot \theta - \csc \theta|; \\ 2 \int \csc^3 \theta d\theta &= \ln |\cot \theta - \csc \theta| - \cot \theta \csc \theta; \\ \int \csc^3 \theta d\theta &= \frac{1}{2} (\ln |\cot \theta - \csc \theta| - \cot \theta \csc \theta). \end{aligned}$$

Now we can finish evaluating the original integral:

$$\begin{aligned}
 9 \int_{\pi/4}^{\pi/2} \csc^3 \theta \, d\theta &= \left[\frac{9}{2} (\ln |\cot \theta - \csc \theta| - \cot \theta \csc \theta) \right]_{\pi/4}^{\pi/2} \\
 &= \frac{9}{2} \left(\ln \left| \cot \frac{\pi}{2} - \csc \frac{\pi}{2} \right| - \cot \frac{\pi}{2} \csc \frac{\pi}{2} \right) - \frac{9}{2} \left(\ln \left| \cot \frac{\pi}{4} - \csc \frac{\pi}{4} \right| - \cot \frac{\pi}{4} \csc \frac{\pi}{4} \right) \\
 &= \frac{9}{2} (\ln |0 - 1| - 0 \cdot 1) - \frac{9}{2} (\ln |1 - \sqrt{2}| - 1 \cdot \sqrt{2}) \\
 &= \frac{9}{2} (\ln 1 - 0) - \frac{9}{2} [\ln (\sqrt{2} - 1) - \sqrt{2}] \\
 &= \frac{9}{2} \cdot 0 + \frac{9}{2} [\sqrt{2} - \ln (\sqrt{2} - 1)] = \boxed{\frac{9 [\sqrt{2} - \ln (\sqrt{2} - 1)]}{2}}.
 \end{aligned}$$

31. The region R associated with the integral $\int_{-2}^2 \int_0^{\sqrt{4-y^2}} (x^2 + y^2) \, dx \, dy$ is enclosed between $x = 0$ and $x = \sqrt{4 - y^2}$, where $-2 \leq y \leq 2$. This is half of the disk of radius 2 centered at the origin lying to the right of the y -axis, as shown in the figure below. In polar coordinates R is given by $0 \leq r \leq 2$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Also, the integrand can be simplified as $x^2 + y^2 = r^2$. Then

$$\begin{aligned}
 \int_{-2}^2 \int_0^{\sqrt{4-y^2}} (x^2 + y^2) \, dx \, dy &= \iint_R (x^2 + y^2) \, dA = \int_{-\pi/2}^{\pi/2} \int_0^2 r^2 \cdot r \, dr \, d\theta \\
 &= \int_{-\pi/2}^{\pi/2} \int_0^2 r^3 \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} \left[\frac{r^4}{4} \right]_0^2 \, d\theta = \int_{-\pi/2}^{\pi/2} (4 - 0) \, d\theta \\
 &= 4 \int_{-\pi/2}^{\pi/2} d\theta = 4 [\theta]_{-\pi/2}^{\pi/2} = 4 \left(\frac{\pi}{2} + \frac{\pi}{2} \right) = \boxed{4\pi}.
 \end{aligned}$$

32. The region R associated with the integral $\int_0^2 \int_0^{\sqrt{4-x^2}} \sqrt{4-x^2-y^2} dy dx$ is enclosed between $y = 0$ and $y = \sqrt{4-x^2}$, where $0 \leq x \leq 2$. This is the first-quadrant quarter of the disk of radius 2 centered at the origin, as shown in the figure below. In polar coordinates R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, the integrand can be simplified as $\sqrt{4-x^2-y^2} = \sqrt{4-(x^2+y^2)} = \sqrt{4-r^2}$. Then

$$\int_0^2 \int_0^{\sqrt{4-x^2}} \sqrt{4-x^2-y^2} dy dx = \iint_R \sqrt{4-x^2-y^2} dA = \int_0^{\pi/2} \int_0^2 \sqrt{4-r^2} \cdot r dr d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^2 \sqrt{4-r^2} \cdot r dr$. In this integral we make a substitution $u = 4 - r^2$; then $du = -2rdr$, so $rdr = -\frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = 4 - 0^2 = 4$; if $r = 2$, then $u = 4 - 2^2 = 0$. So

$$\begin{aligned} \int_0^2 \sqrt{4-r^2} \cdot r dr &= \int_4^0 \sqrt{u} \left(-\frac{du}{2}\right) = -\frac{1}{2} \int_4^0 u^{1/2} du = \frac{1}{2} \int_0^4 u^{1/2} du \\ &= \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_0^4 = \frac{1}{3} [(\sqrt{u})^3]_0^4 = \frac{1}{3} [(\sqrt{4})^3 - (\sqrt{0})^3] = \frac{1}{3} \cdot (8 - 0) = \frac{8}{3}. \end{aligned}$$

Going back to the iterated integral,

$$\int_0^{\pi/2} \int_0^2 \sqrt{4-r^2} \cdot r dr d\theta = \int_0^{\pi/2} \frac{8}{3} d\theta = \frac{8}{3} [\theta]_0^{\pi/2} = \frac{8}{3} \cdot \left(\frac{\pi}{2} - 0\right) = \boxed{\frac{4\pi}{3}}.$$

33. The region R associated with the integral $\int_0^1 \int_0^{\sqrt{1-x^2}} \cos(x^2 + y^2) dy dx$ is enclosed between $y = 0$ and $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. This is the first-quadrant quarter of the disk of radius 1 centered at the origin, as shown in the figure below. In polar coordinates R is given by $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, in the integrand we can simplify $x^2 + y^2 = r^2$. Then

$$\int_0^1 \int_0^{\sqrt{1-x^2}} \cos(x^2 + y^2) dy dx = \iint_R \cos(x^2 + y^2) dA = \int_0^{\pi/2} \int_0^1 \cos(r^2) \cdot r dr d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^1 \cos(r^2) \cdot r dr$. In this integral we make a substitution $u = r^2$; then $du = 2rdr$, so $rdr = \frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = 0^2 = 0$; if $r = 1$, then $u = 1^2 = 1$. So

$$\int_0^1 \cos(r^2) \cdot r dr = \int_0^1 \cos u \cdot \frac{du}{2} = \frac{1}{2} \int_0^1 \cos u du = \frac{1}{2} [\sin u]_0^1 = \frac{1}{2} (\sin 1 - \sin 0) = \frac{\sin 1}{2}.$$

Going back to the iterated integral,

$$\int_0^{\pi/2} \int_0^1 \cos(r^2) \cdot r \, dr \, d\theta = \int_0^{\pi/2} \frac{\sin 1}{2} \, d\theta = \frac{\sin 1}{2} [\theta]_0^{\pi/2} = \frac{\sin 1}{2} \cdot \left(\frac{\pi}{2} - 0\right) = \boxed{\frac{\pi \sin 1}{4}}.$$

34. The region R associated with the integral $\int_0^1 \int_0^{\sqrt{1-y^2}} e^{\sqrt{x^2+y^2}} \, dx \, dy$ is enclosed between $x = 0$ and $x = \sqrt{1-y^2}$, where $0 \leq y \leq 1$. This is the first-quadrant quarter of the disk of radius 1 centered at the origin, as shown in the figure below. In polar coordinates R is given by $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, in the integrand we can simplify $\sqrt{x^2+y^2} = r$. Then

$$\int_0^1 \int_0^{\sqrt{1-y^2}} e^{\sqrt{x^2+y^2}} \, dx \, dy = \iint_R e^{\sqrt{x^2+y^2}} \, dA = \int_0^{\pi/2} \int_0^1 e^r r \, dr \, d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^1 e^r r \, dr$. We find this integral using the method of integration by parts. If we choose $u = r$ and $dv = e^r dr$, then $du = dr$ and $v = \int e^r dr = e^r$. So

$$\int_0^1 e^r r \, dr = [re^r]_0^1 - \int_0^1 e^r \, dr = (1e^1 - 0e^0) - [e^r]_0^1 = e - (e^1 - e^0) = e - e + 1 = 1.$$

Going back to the iterated integral,

$$\int_0^{\pi/2} \int_0^1 e^r r \, dr \, d\theta = \int_0^{\pi/2} 1 \, d\theta = [\theta]_0^{\pi/2} = \frac{\pi}{2} - 0 = \boxed{\frac{\pi}{2}}.$$

35. The region R enclosed in the first quadrant by the circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 4$ is shown in the figure below. In polar coordinates, this region R is given as $1 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, in the integrand we can simplify $x^2 + y^2 = r^2$. Then

$$\iint_R e^{-(x^2+y^2)} \, dA = \int_0^{\pi/2} \int_1^2 e^{-r^2} r \, dr \, d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_1^2 e^{-r^2} r \, dr$. In this integral we make a substitution $u = -r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{du}{2}$. We also change the limits of integration: if $r = 1$, then $u = -1^2 = -1$; if $r = 2$, then $u = -2^2 = -4$. So

$$\begin{aligned} \int_1^2 e^{-r^2} r \, dr &= \int_{-1}^{-4} e^u \left(-\frac{du}{2} \right) = -\frac{1}{2} \int_{-1}^{-4} e^u \, du = \frac{1}{2} \int_{-4}^{-1} e^u \, du \\ &= \frac{1}{2} [e^u]_{-4}^{-1} = \frac{1}{2} (e^{-1} - e^{-4}) = \frac{1}{2} \left(\frac{1}{e} - \frac{1}{e^4} \right) = \frac{1}{2} \cdot \frac{e^3 - 1}{e^4} = \frac{e^3 - 1}{2e^4}. \end{aligned}$$

Going back to the iterated integral,

$$\int_0^{\pi/2} \int_1^2 e^{-r^2} r \, dr \, d\theta = \int_0^{\pi/2} \frac{e^3 - 1}{2e^4} \, d\theta = \frac{e^3 - 1}{2e^4} [\theta]_0^{\pi/2} = \frac{e^3 - 1}{2e^4} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi(e^3 - 1)}{4e^4}}.$$

36. The region R enclosed in the first quadrant by the circle $x^2 + y^2 = a^2$ is shown in the figure below. In polar coordinates, this region R is given as $0 \leq r \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, the integrand simplifies as

$$\frac{y}{\sqrt{x^2 + y^2}} = \frac{r \sin \theta}{r} = \sin \theta. \text{ Then}$$

$$\begin{aligned} \iint_R \frac{y}{\sqrt{x^2 + y^2}} \, dA &= \int_0^{\pi/2} \int_0^a \sin \theta \cdot r \, dr \, d\theta = \int_0^{\pi/2} \sin \theta \left[\int_0^a r \, dr \right] d\theta \\ &= \int_0^{\pi/2} \sin \theta \left[\frac{r^2}{2} \right]_0^a d\theta = \int_0^{\pi/2} \sin \theta \left(\frac{a^2}{2} - 0 \right) d\theta = \frac{a^2}{2} \int_0^{\pi/2} \sin \theta \, d\theta \\ &= \frac{a^2}{2} [-\cos \theta]_0^{\pi/2} = \frac{a^2}{2} \left(-\cos \frac{\pi}{2} + \cos 0 \right) = \frac{a^2}{2} (-0 + 1) = \boxed{\frac{a^2}{2}}. \end{aligned}$$

37. First, we convert the equation of the boundary of the given region R to polar coordinates:

$$\begin{aligned}x^2 + y^2 &= x \\r^2 &= r \cos \theta \\r &= \cos \theta\end{aligned}$$

So R is enclosed by the circle $r = \cos \theta$, as shown in the figure below. In polar coordinates, this region R is given as $0 \leq r \leq \cos \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Also, in the integrand we substitute $x = r \cos \theta$. Then

$$\begin{aligned}\iint_R x \, dA &= \int_{-\pi/2}^{\pi/2} \int_0^{\cos \theta} r \cos \theta \cdot r \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} \cos \theta \left[\int_0^{\cos \theta} r^2 \, dr \right] d\theta \\&= \int_{-\pi/2}^{\pi/2} \cos \theta \left[\frac{r^3}{3} \right]_0^{\cos \theta} d\theta = \int_{-\pi/2}^{\pi/2} \frac{1}{3} \cos \theta [(\cos \theta)^3 - 0] d\theta = \frac{1}{3} \int_{-\pi/2}^{\pi/2} \cos^4 \theta \, d\theta \\&= \frac{1}{3} \int_{-\pi/2}^{\pi/2} \left[\frac{1}{2}(1 + \cos(2\theta)) \right]^2 d\theta = \frac{1}{12} \int_{-\pi/2}^{\pi/2} (1 + 2\cos(2\theta) + \cos^2(2\theta)) d\theta \\&= \frac{1}{12} \int_{-\pi/2}^{\pi/2} \left[1 + 2\cos(2\theta) + \frac{1}{2}(1 + \cos(4\theta)) \right] d\theta = \frac{1}{12} \int_{-\pi/2}^{\pi/2} \left(\frac{3}{2} + 2\cos(2\theta) + \frac{1}{2}\cos(4\theta) \right) d\theta \\&= \frac{1}{12} \left[\frac{3}{2}\theta + 2 \cdot \frac{\sin(2\theta)}{2} + \frac{1}{2} \cdot \frac{\sin(4\theta)}{4} \right]_{-\pi/2}^{\pi/2} = \frac{1}{12} \left[\frac{3}{2}\theta + \sin(2\theta) + \frac{1}{8}\sin(4\theta) \right]_{-\pi/2}^{\pi/2} \\&= \frac{1}{12} \left[\left(\frac{3}{2} \cdot \frac{\pi}{2} + \sin \pi + \frac{1}{8}\sin(2\pi) \right) - \left(\frac{3}{2} \cdot \left(-\frac{\pi}{2} \right) + \sin(-\pi) + \frac{1}{8}\sin(-2\pi) \right) \right] \\&= \frac{1}{12} \left[\left(\frac{3\pi}{4} + 0 + 0 \right) - \left(-\frac{3\pi}{4} + 0 + 0 \right) \right] = \frac{1}{12} \cdot \frac{3\pi}{2} = \boxed{\frac{\pi}{8}}.\end{aligned}$$

38. First, we convert the equation of the boundary of the given region R to polar coordinates:

$$\begin{aligned}x^2 + y^2 &= 2y \\r^2 &= 2r \sin \theta \\r &= 2 \sin \theta\end{aligned}$$

So R is enclosed by the circle $r = 2 \sin \theta$, as shown in the figure below. In polar coordinates, this region

R is given as $0 \leq r \leq 2 \sin \theta$, $0 \leq \theta \leq \pi$. Also, in the integrand we substitute $y = r \sin \theta$. Then

$$\begin{aligned}
 \iint_R y^2 dA &= \int_0^\pi \int_0^{2 \sin \theta} (r \sin \theta)^2 \cdot r dr d\theta = \int_0^\pi \sin^2 \theta \left[\int_0^{2 \sin \theta} r^3 dr \right] d\theta \\
 &= \int_0^\pi \sin^2 \theta \left[\frac{r^4}{4} \right]_0^{2 \sin \theta} d\theta = \int_0^\pi \sin^2 \theta \left[\frac{(2 \sin \theta)^4}{4} - 0 \right] d\theta = \int_0^\pi 4 \sin^6 \theta d\theta \\
 &= 4 \int_0^\pi \left[\frac{1}{2} (1 - \cos(2\theta)) \right]^3 d\theta = \frac{1}{2} \int_0^\pi (1 - 3 \cos(2\theta) + 3 \cos^2(2\theta) - \cos^3(2\theta)) d\theta \\
 &= \frac{1}{2} \int_0^\pi \left[1 - 3 \cos(2\theta) + 3 \cdot \frac{1}{2} (1 + \cos(4\theta)) - \cos^3(2\theta) \right] d\theta \\
 &= \frac{1}{2} \int_0^\pi \left(\frac{5}{2} - 3 \cos(2\theta) + \frac{3}{2} \cos(4\theta) - \cos^3(2\theta) \right) d\theta \\
 &= \frac{5}{4} \int_0^\pi d\theta - \frac{3}{2} \int_0^\pi \cos(2\theta) d\theta + \frac{3}{4} \int_0^\pi \cos(4\theta) d\theta - \frac{1}{2} \int_0^\pi \cos^3(2\theta) d\theta.
 \end{aligned}$$

The first three integrals can be evaluated directly:

$$\begin{aligned}
 \frac{5}{4} \int_0^\pi d\theta &= \frac{5}{4} [\theta]_0^\pi = \frac{5}{4} (\pi - 0) = \frac{5\pi}{4}; \\
 \frac{3}{2} \int_0^\pi \cos(2\theta) d\theta &= \frac{3}{2} \left[\frac{\sin(2\theta)}{2} \right]_0^\pi = \frac{3}{4} [\sin(2\theta)]_0^\pi = \frac{3}{4} (\sin(2\pi) - \sin 0) = \frac{3}{4} (0 - 0) = 0; \\
 \frac{3}{4} \int_0^\pi \cos(4\theta) d\theta &= \frac{3}{4} \left[\frac{\sin(4\theta)}{4} \right]_0^\pi = \frac{3}{16} [\sin(4\theta)]_0^\pi = \frac{3}{16} (\sin(4\pi) - \sin 0) = \frac{3}{16} (0 - 0) = 0.
 \end{aligned}$$

To evaluate the last integral, we use a trigonometric identity to transform the integrand $\cos^3(2\theta) = \cos^2(2\theta) \cdot \cos(2\theta) = (1 - \sin^2(2\theta)) \cos(2\theta)$, and then make a substitution $u = \sin(2\theta)$; then $du = 2 \cos(2\theta) d\theta$, so $\cos(2\theta) d\theta = \frac{du}{2}$. We also change the limits of integration: if $\theta = 0$, then $u = \sin 0 = 0$; if $\theta = \pi$, then $u = \sin(2\pi) = 0$. So

$$\frac{1}{2} \int_0^\pi \cos^3(2\theta) d\theta = \frac{1}{2} \int_0^\pi (1 - \sin^2(2\theta)) \cos(2\theta) d\theta = \frac{1}{2} \int_0^0 (1 - u^2) \frac{du}{2} = \frac{1}{4} \int_0^0 (1 - u^2) du = 0.$$

Then the final answer is

$$\frac{5}{4} \int_0^\pi d\theta - \frac{3}{2} \int_0^\pi \cos(2\theta) d\theta + \frac{3}{4} \int_0^\pi \cos(4\theta) d\theta - \frac{1}{2} \int_0^\pi \cos^3(2\theta) d\theta = \frac{5\pi}{4} - 0 + 0 - 0 = \boxed{\frac{5\pi}{4}}.$$

39. The region R enclosed by the cardioid $r = 3 + \cos \theta$ is shown in the figure below. In polar coordinates,

it is given as $0 \leq r \leq 3 + \cos \theta$, $0 \leq \theta \leq 2\pi$. Also, the integrand simplifies as $\sqrt{x^2 + y^2} = r$. Then

$$\begin{aligned}
 \iint_R \sqrt{x^2 + y^2} dA &= \int_0^{2\pi} \int_0^{3+\cos \theta} r \cdot r dr d\theta = \int_0^{2\pi} \int_0^{3+\cos \theta} r^2 dr d\theta \\
 &= \int_0^{2\pi} \left[\frac{r^3}{3} \right]_0^{3+\cos \theta} d\theta = \int_0^{2\pi} \left[\frac{(3 + \cos \theta)^3}{3} - 0 \right] d\theta \\
 &= \int_0^{2\pi} \frac{27 + 27 \cos \theta + 9 \cos^2 \theta + \cos^3 \theta}{3} d\theta \\
 &= \int_0^{2\pi} \left(9 + 9 \cos \theta + 3 \cos^2 \theta + \frac{1}{3} \cos^3 \theta \right) d\theta \\
 &= \int_0^{2\pi} \left[9 + 9 \cos \theta + 3 \cdot \frac{1}{2} (1 + \cos(2\theta)) + \frac{1}{3} \cos^3 \theta \right] d\theta \\
 &= \int_0^{2\pi} \left(\frac{21}{2} + 9 \cos \theta + \frac{3}{2} \cos(2\theta) + \frac{1}{3} \cos^3 \theta \right) d\theta \\
 &= \frac{21}{2} \int_0^{2\pi} d\theta + 9 \int_0^{2\pi} \cos \theta d\theta + \frac{3}{2} \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{3} \int_0^{2\pi} \cos^3 \theta d\theta.
 \end{aligned}$$

The first three integrals can be evaluated directly:

$$\begin{aligned}
 \frac{21}{2} \int_0^{2\pi} d\theta &= \frac{21}{2} [\theta]_0^{2\pi} = \frac{21}{2} (2\pi - 0) = 21\pi; \\
 9 \int_0^{2\pi} \cos \theta d\theta &= 9 [\sin \theta]_0^{2\pi} = 9 (\sin 2\pi - \sin 0) = 9(0 - 0) = 0; \\
 \frac{3}{2} \int_0^{2\pi} \cos(2\theta) d\theta &= \frac{3}{2} \left[\frac{\sin(2\theta)}{2} \right]_0^{2\pi} = \frac{3}{4} [\sin(2\theta)]_0^{2\pi} = \frac{3}{4} (\sin(4\pi) - \sin 0) = \frac{3}{4} (0 - 0) = 0.
 \end{aligned}$$

To evaluate the last integral, we use a trigonometric identity to transform the integrand $\cos^3 \theta = \cos^2 \theta \cdot \cos \theta = (1 - \sin^2 \theta) \cos \theta$, and then make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$. We also change the limits of integration: if $\theta = 0$, then $u = \sin 0 = 0$; if $\theta = 2\pi$, then $u = \sin(2\pi) = 0$. So

$$\frac{1}{3} \int_0^{2\pi} \cos^3 \theta d\theta = \frac{1}{3} \int_0^{2\pi} (1 - \sin^2 \theta) \cos \theta d\theta = \frac{1}{2} \int_0^0 (1 - u^2) du = 0.$$

Then the final answer is

$$\frac{21}{2} \int_0^{2\pi} d\theta + 9 \int_0^{2\pi} \cos \theta d\theta + \frac{3}{2} \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{3} \int_0^{2\pi} \cos^3 \theta d\theta = 21\pi + 0 + 0 + 0 = \boxed{21\pi}.$$

40. The region R enclosed by the cardioid $r = 2(1 + \sin \theta)$ is shown in the figure below. In polar coordinates, it is given as $0 \leq r \leq 2(1 + \sin \theta)$, $0 \leq \theta \leq 2\pi$. Also, the integrand simplifies as $x^2 + y^2 = r^2$. Then

$$\begin{aligned}
 \iint_R (x^2 + y^2) dA &= \int_0^{2\pi} \int_0^{2(1+\sin \theta)} r^2 \cdot r dr d\theta = \int_0^{2\pi} \int_0^{2(1+\sin \theta)} r^3 dr d\theta \\
 &= \int_0^{2\pi} \left[\frac{r^4}{4} \right]_0^{2(1+\sin \theta)} d\theta = \int_0^{2\pi} \left[\frac{2^4(1+\sin \theta)^4}{4} - 0 \right] d\theta \\
 &= \int_0^{2\pi} 4(1 + 4\sin \theta + 6\sin^2 \theta + 4\sin^3 \theta + \sin^4 \theta) d\theta \\
 &= \int_0^{2\pi} (4 + 16\sin \theta + 24\sin^2 \theta + 16\sin^3 \theta + 4\sin^4 \theta) d\theta \\
 &= \int_0^{2\pi} \left[4 + 16\sin \theta + 24 \cdot \frac{1}{2}(1 - \cos(2\theta)) + 16\sin^3 \theta + 4 \left[\frac{1}{2}(1 - \cos(2\theta)) \right]^2 \right] d\theta \\
 &= \int_0^{2\pi} (4 + 16\sin \theta + 12 - 12\cos(2\theta) + 16\sin^3 \theta + 1 - 2\cos(2\theta) + \cos^2(2\theta)) d\theta \\
 &= \int_0^{2\pi} \left[17 + 16\sin \theta - 14\cos(2\theta) + 16\sin^3 \theta + \frac{1}{2}(1 + \cos(4\theta)) \right] d\theta \\
 &= \int_0^{2\pi} \left(\frac{35}{2} + 16\sin \theta - 14\cos(2\theta) + \frac{1}{2}\cos(4\theta) + 16\sin^3 \theta \right) d\theta \\
 &= \frac{35}{2} \int_0^{2\pi} d\theta + 16 \int_0^{2\pi} \sin \theta d\theta - 14 \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{2} \int_0^{2\pi} \cos(4\theta) d\theta + 16 \int_0^{2\pi} \sin^3 \theta d\theta.
 \end{aligned}$$

The first four integrals can be evaluated directly:

$$\begin{aligned}
 \frac{35}{2} \int_0^{2\pi} d\theta &= \frac{35}{2} [\theta]_0^{2\pi} = \frac{35}{2} (2\pi - 0) = 35\pi; \\
 16 \int_0^{2\pi} \sin \theta d\theta &= 16[-\cos \theta]_0^{2\pi} = 16(-\cos(2\pi) + \cos 0) = 16(-1 + 1) = 0; \\
 14 \int_0^{2\pi} \cos(2\theta) d\theta &= 14 \left[\frac{\sin(2\theta)}{2} \right]_0^{2\pi} = 7[\sin(2\theta)]_0^{2\pi} = 7(\sin(4\pi) - \sin 0) = 7(0 - 0) = 0; \\
 \frac{1}{2} \int_0^{2\pi} \cos(4\theta) d\theta &= \frac{1}{2} \left[\frac{\sin(4\theta)}{4} \right]_0^{2\pi} = \frac{1}{8}[\sin(4\theta)]_0^{2\pi} = \frac{1}{8}(\sin(8\pi) - \sin 0) = \frac{1}{8}(0 - 0) = 0.
 \end{aligned}$$

To evaluate the last integral, we use a trigonometric identity to transform the integrand $\sin^3 \theta = \sin^2 \theta \cdot \sin \theta = (1 - \cos^2 \theta) \sin \theta$, and then make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = 0$, then $u = \cos 0 = 1$; if $\theta = 2\pi$, then $u = \cos 2\pi = 1$. So

$$16 \int_0^{2\pi} \sin^3 \theta d\theta = 16 \int_0^{2\pi} (1 - \cos^2 \theta) \sin \theta d\theta = 16 \int_1^1 (1 - u^2) (-du) = -16 \int_1^1 (1 - u^2) du = 0.$$

Then the final answer is

$$\frac{35}{2} \int_0^{2\pi} d\theta + 16 \int_0^{2\pi} \sin \theta d\theta - 14 \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{2} \int_0^{2\pi} \cos(4\theta) d\theta + 16 \int_0^{2\pi} \sin^3 \theta d\theta = 35\pi + 0 - 0 + 0 + 0 = \boxed{35\pi}.$$

41. The region R associated with the integral $\int_{-2}^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} (x^2 + y^2)^2 dx dy$ is enclosed between $x = -\sqrt{4-y^2}$ and $x = \sqrt{4-y^2}$, where $-2 \leq y \leq 2$. This is the disk of radius 2 centered at the origin, as shown in the figure below. In polar coordinates R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$. Also, the integrand simplifies as $(x^2 + y^2)^2 = (r^2)^2 = r^4$. Then

$$\begin{aligned} \int_{-2}^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} (x^2 + y^2)^2 dx dy &= \iint_R (x^2 + y^2)^2 dA = \int_0^{2\pi} \int_0^2 r^4 \cdot r dr d\theta \\ &= \int_0^{2\pi} \int_0^2 r^5 dr d\theta = \int_0^{2\pi} \left[\frac{r^6}{6} \right]_0^2 d\theta = \int_0^{2\pi} \left(\frac{2^6}{6} - 0 \right) d\theta \\ &= \int_0^{2\pi} \frac{64}{6} d\theta = \frac{32}{3} \int_0^{2\pi} d\theta = \frac{32}{3} [\theta]_0^{2\pi} = \frac{32}{3} (2\pi - 0) = \boxed{\frac{64\pi}{3}}. \end{aligned}$$

42. Since in both integrals the integrand is the same, $f(x, y) = 1$, we can treat the given sum of double integrals

$$\int_0^2 \int_{\sqrt{2x-x^2}}^{\sqrt{4x-x^2}} dy dx + \int_2^4 \int_0^{\sqrt{4x-x^2}} dy dx$$

as integration over a region R that has been split into two subregions R_1 and R_2 : the region R_1 is bounded between $y = \sqrt{2x-x^2}$ and $y = \sqrt{4x-x^2}$, where $0 \leq x \leq 2$; and the region R_2 is bounded between $y = 0$ and $y = \sqrt{4x-x^2}$, where $2 \leq x \leq 4$. See the figure below. The two curved boundaries are parts of circles, whose equations can be converted to polar coordinates as follows:

$$\begin{array}{ll} y = \sqrt{2x-x^2} & y = \sqrt{4x-x^2} \\ y^2 = 2x-x^2 & y^2 = 4x-x^2 \\ x^2 + y^2 = 2x & x^2 + y^2 = 4x \\ r^2 = 2r \cos \theta & r^2 = 4r \cos \theta \\ r = 2 \cos \theta & r = 4 \cos \theta \end{array}$$

In polar coordinates R is given by $2 \cos \theta \leq r \leq 4 \cos \theta$, $0 \leq \theta \leq \frac{\pi}{2}$. Then

$$\begin{aligned}
 \int_0^2 \int_{\sqrt{2x-x^2}}^{\sqrt{4x-x^2}} dy dx &+ \int_2^4 \int_0^{\sqrt{4x-x^2}} dy dx = \iint_{R_1} dA + \iint_{R_2} dA = \iint_R dA = \int_0^{\pi/2} \int_{2 \cos \theta}^{4 \cos \theta} r dr d\theta \\
 &= \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_{2 \cos \theta}^{4 \cos \theta} d\theta = \int_0^{\pi/2} \left(\frac{16 \cos^2 \theta}{2} - \frac{4 \cos^2 \theta}{2} \right) d\theta = \int_0^{\pi/2} 6 \cos^2 \theta d\theta \\
 &= \int_0^{\pi/2} 6 \cdot \frac{1}{2} (1 + \cos(2\theta)) d\theta = \int_0^{\pi/2} (3 + 3 \cos(2\theta)) d\theta = \left[3\theta + 3 \cdot \frac{\sin(2\theta)}{2} \right]_0^{\pi/2} \\
 &= \left[3\theta + \frac{3}{2} \sin(2\theta) \right]_0^{\pi/2} = \left(3 \cdot \frac{\pi}{2} + \frac{3}{2} \sin \pi \right) - \left(3 \cdot 0 + \frac{3}{2} \sin 0 \right) \\
 &= \left(\frac{3\pi}{2} + 0 \right) - (0 + 0) = \boxed{\frac{3\pi}{2}}.
 \end{aligned}$$

Applications and Extensions

43. We begin by graphing the ellipsoid $x^2 + y^2 + 4z^2 = 4$; see figure (a) below. Since it is symmetric about the xy -plane, to find the volume of the entire ellipsoid we can find the volume of its upper half lying above the xy -plane and multiply it by 2. We solve for z assuming $z \geq 0$ to find the equation of the upper half of the ellipsoid: $z = \sqrt{1 - \frac{x^2}{4} - \frac{y^2}{4}}$. To determine the region R that is the intersection of the ellipsoid with the xy -plane, we let $z = 0$ and find that $x^2 + y^2 = 4$, so R is a disk of radius 2 centered at the origin; see figure (b) below. In polar coordinates it is given by $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$. Also, the equation of the surface of the ellipsoid simplifies as $z = \sqrt{1 - \frac{x^2}{4} - \frac{y^2}{4}} = \sqrt{1 - \frac{x^2 + y^2}{4}} = \sqrt{1 - \frac{r^2}{4}}$. Then the volume is

$$V = 2 \iint_R \sqrt{1 - \frac{x^2}{4} - \frac{y^2}{4}} dA = 2 \int_0^{2\pi} \int_0^2 \sqrt{1 - \frac{r^2}{4}} \cdot r dr d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^2 \sqrt{1 - r^2/4} \cdot r dr$. In this integral we make a substitution $u = 1 - \frac{r^2}{4}$; then $du = -\frac{1}{2}rdr$, so $rdr = -2du$. We also change the limits of integration: if $r = 0$, then $u = 1 - \frac{0^2}{4} = 1$; if $r = 2$, then $u = 1 - \frac{2^2}{4} = 0$. So

$$\begin{aligned}
 \int_0^2 \sqrt{1 - \frac{r^2}{4}} \cdot r dr &= \int_1^0 \sqrt{u} (-2du) = -2 \int_1^0 u^{1/2} du \\
 &= 2 \int_0^1 u^{1/2} du = 2 \left[\frac{u^{3/2}}{3/2} \right]_0^1 = \frac{4}{3} \left[u^{3/2} \right]_0^1 = \frac{4}{3} (1 - 0) = \frac{4}{3}.
 \end{aligned}$$

Going back to the iterated integral,

$$V = 2 \int_0^{2\pi} \int_0^2 \sqrt{1 - \frac{r^2}{4}} \cdot r \, dr \, d\theta = 2 \int_0^{2\pi} \frac{4}{3} d\theta = \frac{8}{3} [\theta]_0^{2\pi} = \frac{8}{3} (2\pi - 0) = \boxed{\frac{16\pi}{3} \text{ cubic units}}.$$

(a)

(b)

44. We begin by graphing the solid enclosed by the paraboloid $x^2 + y^2 = az$, the xy -plane, and the cylinder $x^2 + y^2 = a^2$; see figure (a) below. It is bounded from below by the plane $z = 0$, from above by the paraboloid $z = \frac{1}{a}(x^2 + y^2)$, and it lies over the region R in the xy -plane that is the base of the cylinder $x^2 + y^2 = a^2$. In polar coordinates, R is given by $0 \leq r \leq a$, $0 \leq \theta \leq 2\pi$; see figure (b) below. Also, the equation of the surface of the paraboloid simplifies as $z = \frac{1}{a}(x^2 + y^2) = \frac{r^2}{a}$. Then the volume is

$$\begin{aligned} V &= \iint_R \frac{1}{a}(x^2 + y^2) \, dA = \int_0^{2\pi} \int_0^a \frac{r^2}{a} \cdot r \, dr \, d\theta = \int_0^{2\pi} \int_0^a \frac{1}{a} r^3 \, dr \, d\theta = \int_0^{2\pi} \frac{1}{a} \left[\frac{r^4}{4} \right]_0^a d\theta \\ &= \int_0^{2\pi} \frac{1}{a} \left(\frac{a^4}{4} - 0 \right) d\theta = \int_0^{2\pi} \frac{a^3}{4} d\theta = \frac{a^3}{4} [\theta]_0^{2\pi} = \frac{a^3}{4} (2\pi - 0) = \boxed{\frac{\pi a^3}{2} \text{ cubic units}}. \end{aligned}$$

(a)

(b)

45. The solid shown in the figure in Problem 45 is bounded from below by the plane $z = 0$, from above by the upper hemisphere $z = \sqrt{16 - x^2 - y^2}$, and it lies over the region R in the xy -plane bounded by the circle $r = 4 \sin \theta$. Observe that this solid (and the region R) is symmetric about the yz -plane, so we can find the volume of its half lying to the right of the yz -plane, that is over the half of R to the right of the y -axis, and multiply it by 2. The half of the region R to the right of the y -axis is given

by $0 \leq r \leq 4 \sin \theta$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, in polar coordinates, the equation of the hemisphere simplifies as $z = \sqrt{16 - x^2 - y^2} = \sqrt{16 - (x^2 + y^2)} = \sqrt{16 - r^2}$. Then the volume is

$$V = \iint_R \sqrt{16 - x^2 - y^2} \, dA = 2 \int_0^{\pi/2} \int_0^{4 \sin \theta} \sqrt{16 - r^2} \cdot r \, dr \, d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^{4 \sin \theta} \sqrt{16 - r^2} \cdot r \, dr$. In this integral we make a substitution $u = 16 - r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = 16 - 0^2 = 16$; if $r = 4 \sin \theta$, then $u = 16 - (4 \sin \theta)^2 = 16 - 16 \sin^2 \theta = 16(1 - \sin^2 \theta) = 16 \cos^2 \theta$. So

$$\begin{aligned} \int_0^{4 \sin \theta} \sqrt{16 - r^2} \cdot r \, dr &= \int_{16}^{16 \cos^2 \theta} \sqrt{u} \left(-\frac{du}{2} \right) = -\frac{1}{2} \int_{16}^{16 \cos^2 \theta} u^{1/2} \, du \\ &= \frac{1}{2} \int_{16 \cos^2 \theta}^{16} u^{1/2} \, du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_{16 \cos^2 \theta}^{16} = \frac{1}{3} \left[(\sqrt{u})^3 \right]_{16 \cos^2 \theta}^{16} \\ &= \frac{1}{3} \left[(\sqrt{16})^3 - (\sqrt{16 \cos^2 \theta})^3 \right] = \frac{1}{3} (64 - 64 \cos^3 \theta) = \frac{64}{3} (1 - \cos^3 \theta), \end{aligned}$$

where we used the fact that $\sqrt{\cos^2 \theta} = \cos \theta$, because $0 \leq \theta \leq \frac{\pi}{2}$ and so $\cos \theta \geq 0$. Going back to the iterated integral,

$$\begin{aligned} V &= 2 \int_0^{\pi/2} \int_0^{4 \sin \theta} \sqrt{16 - r^2} \cdot r \, dr \, d\theta = 2 \int_0^{\pi/2} \frac{64}{3} (1 - \cos^3 \theta) \, d\theta \\ &= \frac{128}{3} \int_0^{\pi/2} (1 - \cos^3 \theta) \, d\theta = \frac{128}{3} \int_0^{\pi/2} d\theta - \frac{128}{3} \int_0^{\pi/2} \cos^3 \theta \, d\theta. \end{aligned}$$

The first integral can be evaluated directly:

$$\frac{128}{3} \int_0^{\pi/2} d\theta = \frac{128}{3} [\theta]_0^{\pi/2} = \frac{128}{3} \left(\frac{\pi}{2} - 0 \right) = \frac{64\pi}{3}.$$

To evaluate the second integral, we use a trigonometric identity to transform the integrand $\cos^3 \theta = \cos^2 \theta \cdot \cos \theta = (1 - \sin^2 \theta) \cos \theta$, and then make a substitution $v = \sin \theta$; then $dv = \cos \theta \, d\theta$. We also change the limits of integration: if $\theta = 0$, then $v = \sin 0 = 0$; if $\theta = \frac{\pi}{2}$, then $v = \sin \frac{\pi}{2} = 1$. So

$$\begin{aligned} \frac{128}{3} \int_0^{\pi/2} \cos^3 \theta \, d\theta &= \frac{128}{3} \int_0^{\pi/2} (1 - \sin^2 \theta) \cos \theta \, d\theta = \frac{128}{3} \int_0^1 (1 - v^2) \, dv \\ &= \frac{128}{3} \left[v - \frac{v^3}{3} \right]_0^1 = \frac{128}{3} \left[\left(1 - \frac{1}{3} \right) - (0 - 0) \right] = \frac{128}{3} \cdot \frac{2}{3} = \frac{256}{9}. \end{aligned}$$

Then the final answer is

$$V = \frac{128}{3} \int_0^{\pi/2} d\theta - \frac{128}{3} \int_0^{\pi/2} \cos^3 \theta \, d\theta = \boxed{\frac{64\pi}{3} - \frac{256}{9} \text{ cubic units}}.$$

46. We begin by graphing the solid cut from the ellipsoid $x^2 + y^2 + 4z^2 = 4$ by the cylinder $x^2 + y^2 = 1$; see figure (a) below. Since it is symmetric about the xy -plane, to find the volume of the entire solid we can find the volume of its upper half lying above the xy -plane and multiply it by 2. We solve for z assuming $z \geq 0$ to find the equation of the upper half of the ellipsoid: $z = \sqrt{1 - \frac{x^2}{4} - \frac{y^2}{4}}$.

The equation of the trace of the cylinder in the xy -plane is $x^2 + y^2 = 1$, so it encloses the region R that is the disk of radius 1 centered at the origin; see figure (b) below. In polar coordinates it is given by $0 \leq r \leq 1$, $0 \leq \theta \leq 2\pi$. Also, the equation of the surface of the ellipsoid simplifies as $z = \sqrt{1 - \frac{x^2}{4} - \frac{y^2}{4}} = \sqrt{1 - \frac{x^2 + y^2}{4}} = \sqrt{1 - \frac{r^2}{4}}$. Then the volume is

$$V = 2 \iint_R \sqrt{1 - \frac{x^2}{4} - \frac{y^2}{4}} dA = 2 \int_0^{2\pi} \int_0^1 \sqrt{1 - \frac{r^2}{4}} \cdot r dr d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^1 \sqrt{1 - r^2/4} \cdot r dr$. In this integral we make a substitution $u = 1 - \frac{r^2}{4}$; then $du = -\frac{1}{2}rdr$, so $rdr = -2du$. We also change the limits of integration: if $r = 0$, then $u = 1 - \frac{0^2}{4} = 1$; if $r = 1$, then $u = 1 - \frac{1^2}{4} = \frac{3}{4}$. So

$$\begin{aligned} \int_0^1 \sqrt{1 - \frac{r^2}{4}} \cdot r dr &= \int_1^{3/4} \sqrt{u} (-2du) = -2 \int_1^{3/4} u^{1/2} du = 2 \int_{3/4}^1 u^{1/2} du = 2 \left[\frac{u^{3/2}}{3/2} \right]_{3/4}^1 \\ &= \frac{4}{3} \left[(\sqrt{u})^3 \right]_{3/4}^1 = \frac{4}{3} \left[(\sqrt{1})^3 - \left(\sqrt{\frac{3}{4}} \right)^3 \right] = \frac{4}{3} \left(1 - \frac{3\sqrt{3}}{8} \right) = \frac{4}{3} - \frac{\sqrt{3}}{2}. \end{aligned}$$

Going back to the iterated integral,

$$\begin{aligned} V &= 2 \int_0^{2\pi} \int_0^1 \sqrt{1 - \frac{r^2}{4}} \cdot r dr d\theta = 2 \int_0^{2\pi} \left(\frac{4}{3} - \frac{\sqrt{3}}{2} \right) d\theta \\ &= \left(\frac{8}{3} - \sqrt{3} \right) [\theta]_0^{2\pi} = \left(\frac{8}{3} - \sqrt{3} \right) (2\pi - 0) = \boxed{\frac{(16 - 6\sqrt{3})\pi}{3} \text{ cubic units}}. \end{aligned}$$

47. We begin by graphing the polar curve $r^2 = 9 \sin(2\theta)$, shown in the figure below. The graph consists of two similar loops. The loop lying in the first quadrant encloses the region R that can be defined in

polar coordinates as $0 \leq r \leq 3\sqrt{\sin(2\theta)}$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the area of this region can be found as

$$\begin{aligned}
 A &= \iint_R dA = \int_0^{\pi/2} \int_0^{3\sqrt{\sin(2\theta)}} r \, dr \, d\theta = \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_0^{3\sqrt{\sin(2\theta)}} d\theta \\
 &= \int_0^{\pi/2} \left[\frac{9\sin(2\theta)}{2} - 0 \right] d\theta = \frac{9}{2} \int_0^{\pi/2} \sin(2\theta) \, d\theta = \frac{9}{2} \left[\frac{-\cos(2\theta)}{2} \right]_0^{\pi/2} \\
 &= -\frac{9}{4} [\cos(2\theta)]_0^{\pi/2} = -\frac{9}{4} (\cos \pi - \cos 0) = -\frac{9}{4} (-1 - 1) = \boxed{\frac{9}{2} \text{ square units}}.
 \end{aligned}$$

48. We begin by graphing the region R lying inside the circle $r = 4 \cos \theta$ but outside the circle $r = \cos \theta$; see the figure below. Notice that R is symmetric about the x -axis, so its area can be found by finding the area of its half lying in the upper half-plane and multiplying it by 2. This upper half of the region R can be defined in polar coordinates as $\cos \theta \leq r \leq 4 \cos \theta$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the area of R can be found as

$$\begin{aligned}
 A &= \iint_R dA = 2 \int_0^{\pi/2} \int_{\cos \theta}^{4 \cos \theta} r \, dr \, d\theta = 2 \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_{\cos \theta}^{4 \cos \theta} d\theta = 2 \int_0^{\pi/2} \left[\frac{16 \cos^2 \theta}{2} - \frac{\cos^2 \theta}{2} \right] d\theta \\
 &= 2 \cdot \frac{15}{2} \int_0^{\pi/2} \cos^2 \theta \, d\theta = 15 \int_0^{\pi/2} \frac{1}{2} (1 + \cos(2\theta)) \, d\theta = \frac{15}{2} \left[\theta + \frac{\sin(2\theta)}{2} \right]_0^{\pi/2} \\
 &= \frac{15}{2} \left[\left(\frac{\pi}{2} + \frac{\sin \pi}{2} \right) - \left(0 + \frac{\sin 0}{2} \right) \right] = \frac{15}{2} \left[\left(\frac{\pi}{2} + 0 \right) - (0 + 0) \right] = \boxed{\frac{15\pi}{4} \text{ square units}}.
 \end{aligned}$$

49. The region R that lies in the first quadrant inside the limaçon $r = 3 + 2 \sin \theta$ but outside the circle $r = 4 \sin \theta$, as shown in the figure in Problem 49, can be defined in polar coordinates as $4 \sin \theta \leq r \leq$

$3 + 2 \sin \theta$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the area of R can be found as

$$\begin{aligned}
 A &= \iint_R dA = \int_0^{\pi/2} \int_{4 \sin \theta}^{3+2 \sin \theta} r \, dr \, d\theta = \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_{4 \sin \theta}^{3+2 \sin \theta} d\theta \\
 &= \int_0^{\pi/2} \left[\frac{(3+2 \sin \theta)^2}{2} - \frac{(4 \sin \theta)^2}{2} \right] d\theta = \int_0^{\pi/2} \left(\frac{9+12 \sin \theta+4 \sin^2 \theta}{2} - \frac{16 \sin^2 \theta}{2} \right) d\theta \\
 &= \int_0^{\pi/2} \left(\frac{9}{2} + 6 \sin \theta - 6 \sin^2 \theta \right) d\theta = \int_0^{\pi/2} \left[\frac{9}{2} + 6 \sin \theta - 6 \cdot \frac{1}{2}(1 - \cos(2\theta)) \right] d\theta \\
 &= \int_0^{\pi/2} \left(\frac{9}{2} + 6 \sin \theta - 3 + 3 \cos(2\theta) \right) d\theta = \int_0^{\pi/2} \left(\frac{3}{2} + 6 \sin \theta + 3 \cos(2\theta) \right) d\theta \\
 &= \left[\frac{3}{2}\theta - 6 \cos \theta + \frac{3}{2} \sin(2\theta) \right]_0^{\pi/2} = \left(\frac{3}{2} \cdot \frac{\pi}{2} - 6 \cos \frac{\pi}{2} + \frac{3}{2} \sin \pi \right) - \left(\frac{3}{2} \cdot 0 - 6 \cos 0 + \frac{3}{2} \sin 0 \right) \\
 &= \left[\left(\frac{3\pi}{4} - 0 + 0 \right) - (0 - 6 + 0) \right] = \boxed{\frac{3\pi}{4} + 6 \text{ square units}}.
 \end{aligned}$$

50. We begin by graphing the region R lying inside the circle $r = 1$ but outside the cardioid $r = 1 + \cos \theta$; see the figure below. The graphs intersect at the points where

$$1 + \cos \theta = 1, \quad \text{so} \quad \cos \theta = 0, \quad \text{so} \quad \theta = \pm \frac{\pi}{2}.$$

Notice that R is symmetric about the x -axis, so its area can be found by finding the area of its half lying in the upper half-plane (that is, in the third quadrant) and multiplying it by 2. This upper half of the region R can be defined in polar coordinates as $1 + \cos \theta \leq r \leq 1$, $\frac{\pi}{2} \leq \theta \leq \pi$. Then the area of R can be found as

$$\begin{aligned}
 A &= \iint_R dA = 2 \int_{\pi/2}^{\pi} \int_{1+\cos \theta}^1 r \, dr \, d\theta = 2 \int_{\pi/2}^{\pi} \left[\frac{r^2}{2} \right]_{1+\cos \theta}^1 d\theta = \int_{\pi/2}^{\pi} [r^2]_{1+\cos \theta}^1 d\theta \\
 &= \int_{\pi/2}^{\pi} [1^2 - (1 + \cos \theta)^2] d\theta = \int_{\pi/2}^{\pi} [1 - (1 + 2 \cos \theta + \cos^2 \theta)] d\theta = \int_{\pi/2}^{\pi} (-2 \cos \theta - \cos^2 \theta) d\theta \\
 &= \int_{\pi/2}^{\pi} \left[-2 \cos \theta - \frac{1}{2}(1 + \cos(2\theta)) \right] d\theta = \int_{\pi/2}^{\pi} \left(-\frac{1}{2} - 2 \cos \theta - \frac{1}{2} \cos(2\theta) \right) d\theta \\
 &= \left[-\frac{1}{2}\theta - 2 \sin \theta - \frac{1}{4} \sin(2\theta) \right]_{\pi/2}^{\pi} = \left(-\frac{1}{2} \cdot \pi - 2 \sin \pi - \frac{1}{4} \sin(2\pi) \right) - \left(-\frac{1}{2} \cdot \frac{\pi}{2} - 2 \sin \frac{\pi}{2} - \frac{1}{4} \sin \pi \right) \\
 &= \left(-\frac{\pi}{2} - 0 - 0 \right) - \left(-\frac{\pi}{4} - 2 - 0 \right) = \boxed{2 - \frac{\pi}{4} \text{ square units}}.
 \end{aligned}$$

51. We begin by graphing the region R lying inside the cardioid $r = 1 + \cos \theta$ but outside the circle $r = \frac{1}{2}$; see the figure below. The graphs intersect at the points where

$$1 + \cos \theta = \frac{1}{2}, \quad \text{so} \quad \cos \theta = -\frac{1}{2}, \quad \text{so} \quad \theta = \pm \frac{2\pi}{3}.$$

Notice that R is symmetric about the x -axis, so its area can be found by finding the area of its half lying in the upper half-plane and multiplying it by 2. This upper half of the region R can be defined in polar coordinates as $\frac{1}{2} \leq r \leq 1 + \cos \theta$, $0 \leq \theta \leq \frac{2\pi}{3}$. Then the area of R can be found as

$$\begin{aligned} A &= \iint_R dA = 2 \int_0^{2\pi/3} \int_{1/2}^{1+\cos \theta} r \, dr \, d\theta = 2 \int_0^{2\pi/3} \left[\frac{r^2}{2} \right]_{1/2}^{1+\cos \theta} d\theta = \int_0^{2\pi/3} [r^2]_{1/2}^{1+\cos \theta} d\theta \\ &= \int_0^{2\pi/3} \left[(1 + \cos \theta)^2 - \left(\frac{1}{2} \right)^2 \right] d\theta = \int_0^{2\pi/3} \left[1 + 2 \cos \theta + \cos^2 \theta - \frac{1}{4} \right] d\theta \\ &= \int_0^{2\pi/3} \left(\frac{3}{4} + 2 \cos \theta + \cos^2 \theta \right) d\theta = \int_0^{2\pi/3} \left[\frac{3}{4} + 2 \cos \theta + \frac{1}{2}(1 + \cos(2\theta)) \right] d\theta \\ &= \int_0^{2\pi/3} \left(\frac{5}{4} + 2 \cos \theta + \frac{1}{2} \cos(2\theta) \right) d\theta = \left[\frac{5}{4}\theta + 2 \sin \theta + \frac{1}{4} \sin(2\theta) \right]_0^{2\pi/3} \\ &= \left(\frac{5}{4} \cdot \frac{2\pi}{3} + 2 \sin \frac{2\pi}{3} + \frac{1}{4} \sin \frac{4\pi}{3} \right) - \left(\frac{5}{4} \cdot 0 + 2 \sin 0 + \frac{1}{4} \sin 0 \right) \\ &= \left[\frac{5\pi}{6} + 2 \cdot \frac{\sqrt{3}}{2} + \frac{1}{4} \cdot \left(-\frac{\sqrt{3}}{2} \right) \right] - (0 + 0 + 0) \\ &= \frac{5\pi}{6} + \sqrt{3} - \frac{\sqrt{3}}{8} = \boxed{\frac{5\pi}{6} + \frac{7\sqrt{3}}{8} \text{ square units}}. \end{aligned}$$

52. We begin by graphing the region R lying inside the limaçon $r = 3 - \cos \theta$ but outside the circle $r = 5 \cos \theta$; see figure (a) below. The graphs intersect at the points where

$$3 - \cos \theta = 5 \cos \theta, \quad \text{so} \quad 6 \cos \theta = 3, \quad \text{so} \quad \cos \theta = \frac{1}{2}, \quad \text{so} \quad \theta = \pm \frac{\pi}{3}.$$

Notice that R is symmetric about the x -axis, so its area can be found by finding the area of its half lying in the upper half-plane and multiplying it by 2. Moreover, it is convenient to split this upper half of the region R into two subregions: subregion R_1 lying in the first quadrant can be defined in polar coordinates as $5 \cos \theta \leq r \leq 3 - \cos \theta$, $\frac{\pi}{3} \leq \theta \leq \frac{\pi}{2}$; and subregion R_2 lying in the second quadrant can be defined in polar coordinates as $0 \leq r \leq 3 - \cos \theta$, $\frac{\pi}{2} \leq \theta \leq \pi$; see figure (b) below.

The area of the subregion R_1 is

$$\begin{aligned}
 A_{R_1} &= \iint_{R_1} dA = \int_{\pi/3}^{\pi/2} \int_{5 \cos \theta}^{3 - \cos \theta} r \, dr \, d\theta = \int_{\pi/3}^{\pi/2} \left[\frac{r^2}{2} \right]_{5 \cos \theta}^{3 - \cos \theta} d\theta \\
 &= \int_{\pi/3}^{\pi/2} \left[\frac{(3 - \cos \theta)^2}{2} - \frac{(5 \cos \theta)^2}{2} \right] d\theta = \int_{\pi/3}^{\pi/2} \left(\frac{9 - 6 \cos \theta + \cos^2 \theta}{2} - \frac{25 \cos^2 \theta}{2} \right) d\theta \\
 &= \int_{\pi/3}^{\pi/2} \left(\frac{9}{2} - 3 \cos \theta - 12 \cos^2 \theta \right) d\theta = \int_{\pi/3}^{\pi/2} \left[\frac{9}{2} - 3 \cos \theta - 12 \cdot \frac{1}{2} (1 + \cos(2\theta)) \right] d\theta \\
 &= \int_{\pi/3}^{\pi/2} \left(-\frac{3}{2} - 3 \cos \theta - 6 \cos(2\theta) \right) d\theta = \left[-\frac{3}{2} \theta - 3 \sin \theta - 3 \sin(2\theta) \right]_{\pi/3}^{\pi/2} \\
 &= \left(-\frac{3}{2} \cdot \frac{\pi}{2} - 3 \sin \frac{\pi}{2} - 3 \sin \pi \right) - \left(-\frac{3}{2} \cdot \frac{\pi}{3} - 3 \sin \frac{\pi}{3} - 3 \sin \frac{2\pi}{3} \right) \\
 &= \left(-\frac{3\pi}{4} - 3 \cdot 1 - 3 \cdot 0 \right) - \left(-\frac{\pi}{2} - 3 \cdot \frac{\sqrt{3}}{2} - 3 \cdot \frac{\sqrt{3}}{2} \right) \\
 &= -\frac{3\pi}{4} - 3 - 0 + \frac{\pi}{2} + \frac{3\sqrt{3}}{2} + \frac{3\sqrt{3}}{2} = 3\sqrt{3} - 3 - \frac{\pi}{4}.
 \end{aligned}$$

The area of the subregion R_2 is

$$\begin{aligned}
 A_{R_2} &= \iint_{R_2} dA = \int_{\pi/2}^{\pi} \int_0^{3 - \cos \theta} r \, dr \, d\theta = \int_{\pi/2}^{\pi} \left[\frac{r^2}{2} \right]_0^{3 - \cos \theta} d\theta \\
 &= \int_{\pi/2}^{\pi} \left[\frac{(3 - \cos \theta)^2}{2} - 0 \right] d\theta = \int_{\pi/2}^{\pi} \frac{9 - 6 \cos \theta + \cos^2 \theta}{2} d\theta \\
 &= \int_{\pi/2}^{\pi} \left(\frac{9}{2} - 3 \cos \theta + \frac{1}{2} \cos^2 \theta \right) d\theta = \int_{\pi/2}^{\pi} \left[\frac{9}{2} - 3 \cos \theta + \frac{1}{2} \cdot \frac{1}{2} (1 + \cos(2\theta)) \right] d\theta \\
 &= \int_{\pi/2}^{\pi} \left(\frac{19}{4} - 3 \cos \theta + \frac{1}{4} \cos(2\theta) \right) d\theta = \left[\frac{19}{4} \theta - 3 \sin \theta + \frac{1}{8} \sin(2\theta) \right]_{\pi/2}^{\pi} \\
 &= \left(\frac{19}{4} \cdot \pi - 3 \sin \pi + \frac{1}{8} \sin(2\pi) \right) - \left(\frac{19}{4} \cdot \frac{\pi}{2} - 3 \sin \frac{\pi}{2} + \frac{1}{8} \sin \pi \right) \\
 &= \left(\frac{19\pi}{4} - 3 \cdot 0 + \frac{1}{8} \cdot 0 \right) - \left(\frac{19\pi}{8} - 3 \cdot 1 + \frac{1}{8} \cdot 0 \right) = \frac{19\pi}{8} + 3.
 \end{aligned}$$

Finally, the area of the entire region R is

$$\begin{aligned} A_R &= 2(A_{R_1} + A_{R_2}) = 2 \left[\left(3\sqrt{3} - 3 - \frac{\pi}{4} \right) + \left(\frac{19\pi}{8} + 3 \right) \right] \\ &= 2 \left(3\sqrt{3} + \frac{17\pi}{8} \right) = \boxed{6\sqrt{3} + \frac{17\pi}{4} \text{ square units}}. \end{aligned}$$

53. The region R associated with the integral $\int_0^{1/\sqrt{2}} \int_0^{\sin^{-1} r} r \, d\theta \, dr$ is enclosed between $\theta = 0$ (the positive x -axis) and $\theta = \sin^{-1} r$, where $0 \leq r \leq \frac{1}{\sqrt{2}}$. In other words, for each value of the polar radius r , $0 \leq r \leq \frac{1}{\sqrt{2}}$, the polar angle θ ranges from $\theta = 0$ to $\theta = \sin^{-1} r$. This region R is shown in the figure below. Notice that R is a y -simple region. To obtain equations of the bounding curves, we convert them from polar to cartesian coordinates:

$$\begin{aligned} \theta &= \sin^{-1} r & r &= \frac{1}{\sqrt{2}} \\ r &= \sin \theta & r^2 &= \frac{1}{2} \\ r^2 &= r \sin \theta & x^2 + y^2 &= \frac{1}{2} \\ x^2 + y^2 &= y & x^2 &= \frac{1}{2} - y^2 \\ x^2 &= y - y^2 & x &= \sqrt{\frac{1}{2} - y^2} \\ x &= \sqrt{y - y^2} \end{aligned}$$

The point of intersection of the two graphs can be found by setting their equations equal to each other:

$$\sqrt{y - y^2} = \sqrt{\frac{1}{2} - y^2}, \quad \text{so } y - y^2 = \frac{1}{2} - y^2, \quad \text{so } y = \frac{1}{2}, \quad \text{and } x = \sqrt{y - y^2} = \sqrt{\frac{1}{2} - \frac{1}{4}} = \frac{1}{2}.$$

Finally, since $r \, d\theta \, dr = dA$, the given integral can be rewritten as

$$\int_0^{1/\sqrt{2}} \int_0^{\sin^{-1} r} r \, d\theta \, dr = \iint_R dA = \boxed{\int_0^{1/2} \int_{\sqrt{y-y^2}}^{\sqrt{\frac{1}{2}-y^2}} dx \, dy}.$$

54. The region R associated with the integral $\int_0^1 \int_{\cos^{-1} r}^{\pi/2} r^2 \sin \theta \, d\theta \, dr$ is enclosed between $\theta = \cos^{-1} r$ and $\theta = \frac{\pi}{2}$ (the positive y -axis), where $0 \leq r \leq 1$. In other words, for each value of the polar radius r , $0 \leq r \leq 1$, the polar angle θ ranges from $\theta = \cos^{-1} r$ to $\theta = \frac{\pi}{2}$. This region R is shown in the figure

below. Notice that R is an x -simple region. To obtain equations of the bounding curves, we convert them from polar to cartesian coordinates:

$$\begin{array}{ll} \theta = \cos^{-1} r & r = 1 \\ r = \cos \theta & r^2 = 1 \\ r^2 = r \cos \theta & x^2 + y^2 = 1 \\ x^2 + y^2 = x & y^2 = 1 - x^2 \\ y^2 = x - x^2 & y = \sqrt{1 - x^2} \\ y = \sqrt{x - x^2} & \end{array}$$

The point of intersection of the two graphs can be found by setting their equations equal to each other:

$$\sqrt{x - x^2} = \sqrt{1 - x^2}, \quad \text{so } x - x^2 = 1 - x^2, \quad \text{so } x = 1, \quad \text{and } y = \sqrt{x - x^2} = \sqrt{1 - 1} = 0.$$

Finally, since $r^2 \sin \theta \, d\theta \, dr = r \sin \theta \cdot r \, d\theta \, dr = y \, dA$, the given integral can be rewritten as

$$\int_0^1 \int_{\cos^{-1} r}^{\pi/2} r^2 \sin \theta \, d\theta \, dr = \iint_R y \, dA = \boxed{\int_0^1 \int_{\sqrt{x-x^2}}^{\sqrt{1-x^2}} y \, dy \, dx}.$$

55. The volume of the entire hemisphere tank is: $V_{\text{tank}} = \frac{1}{2} V_{\text{sphere}} = \frac{1}{2} \cdot \frac{4}{3} \pi r^3 = \frac{1}{2} \cdot \frac{4}{3} \pi \cdot 1^3 = \frac{2\pi}{3} \text{ m}^3$. Then we can find the volume of the liquid in the tank, which is filled up to a depth of a meters, $0 \leq a \leq 1$, as shown in the figure in Problem 55, if we find the volume of the empty cap above the liquid level and subtract it from the volume of the tank.

The empty cap above the water level can be represented as the solid enclosed between $z = f_1(x, y) = a$ and $z = f_2(x, y) = \sqrt{1 - x^2 - y^2}$ over the region R in the xy -plane, that is bounded by the trace obtained as the intersection of the hemisphere with the plane $z = a$; the equation of this trace is $x^2 + y^2 + a^2 = 1$ or $x^2 + y^2 = 1 - a^2$. So we can find the volume of the empty cap as the double integral

$$V_{\text{cap}} = \iint_R [f_2(x, y) - f_1(x, y)] \, dA = \iint_R (\sqrt{1 - x^2 - y^2} - a) \, dA.$$

In polar coordinates, the region R can be described as $0 \leq r \leq \sqrt{1 - a^2}$, $0 \leq \theta \leq 2\pi$. Also, in the integrand we can simplify $\sqrt{1 - x^2 - y^2} = \sqrt{1 - (x^2 + y^2)} = \sqrt{1 - r^2}$. So this double integral can be converted to polar coordinates as

$$V_{\text{cap}} = \iint_R (\sqrt{1 - x^2 - y^2} - a) \, dA = \int_0^{2\pi} \int_0^{\sqrt{1-a^2}} (\sqrt{1 - r^2} - a) \cdot r \, dr \, d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^{\sqrt{1-a^2}} (\sqrt{1-r^2} - a) \cdot r \, dr$. In this integral we make a substitution $u = 1 - r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = 1 - 0^2 = 1$; if $r = \sqrt{1 - a^2}$, then $u = 1 - (\sqrt{1 - a^2})^2 = 1 - (1 - a^2) = a^2$. So

$$\begin{aligned} \int_0^{\sqrt{1-a^2}} (\sqrt{1-r^2} - a) \cdot r \, dr &= \int_1^{a^2} (\sqrt{u} - a) \cdot \frac{du}{-2} = -\frac{1}{2} \int_1^{a^2} (\sqrt{u} - a) \, du \\ &= \frac{1}{2} \int_{a^2}^1 (u^{1/2} - a) \, du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} - au \right]_{a^2}^1 = \left[\frac{1}{3} (\sqrt{u})^3 - \frac{1}{2} au \right]_{a^2}^1 \\ &= \left[\frac{1}{3} (\sqrt{1})^3 - \frac{1}{2} a \cdot 1 \right] - \left[\frac{1}{3} (\sqrt{a^2})^3 - \frac{1}{2} a \cdot a^2 \right] \\ &= \left(\frac{1}{3} - \frac{a}{2} \right) - \left(\frac{a^3}{3} - \frac{a^3}{2} \right) = \frac{1}{3} - \frac{a}{2} + \frac{a^3}{6} = \frac{2 - 3a + a^3}{6}. \end{aligned}$$

Going back to the iterated integral, the volume of the empty cap is

$$\begin{aligned} V_{\text{cap}} &= \int_0^{2\pi} \int_0^{\sqrt{1-a^2}} (\sqrt{1-r^2} - a) \cdot r \, dr \, d\theta = \int_0^{2\pi} \frac{2 - 3a + a^3}{6} \, d\theta \\ &= \frac{2 - 3a + a^3}{6} \cdot [\theta]_0^{2\pi} = \frac{2 - 3a + a^3}{6} \cdot (2\pi - 0) = \frac{(2 - 3a + a^3)\pi}{3} \, \text{m}^3, \end{aligned}$$

and the volume of the liquid is

$$V_{\text{liquid}} = V_{\text{tank}} - V_{\text{cap}} = \frac{2\pi}{3} - \frac{(2 - 3a + a^3)\pi}{3} = \frac{(3a - a^3)\pi}{3} = \boxed{\pi a \left(1 - \frac{a^2}{3} \right) \, \text{m}^3}.$$

56. The volume of the liquid in the tank, which is filled up to a depth of a meters, $-1 \leq a \leq 0$, as shown in the figure in Problem 56, can be represented as the volume of the solid enclosed between $z = f_1(x, y) = -\sqrt{1 - x^2 - y^2}$ and $z = f_2(x, y) = a$ over the region R in the xy -plane, that is bounded by the trace obtained as the intersection of the hemisphere with the plane $z = a$; the equation of this trace is $x^2 + y^2 + a^2 = 1$ or $x^2 + y^2 = 1 - a^2$. So we can find this volume as the double integral

$$V = \iint_R [f_2(x, y) - f_1(x, y)] \, dA = \iint_R (a + \sqrt{1 - x^2 - y^2}) \, dA.$$

In polar coordinates, the region R can be described as $0 \leq r \leq \sqrt{1 - a^2}$, $0 \leq \theta \leq 2\pi$. Also, in the integrand we can simplify $\sqrt{1 - x^2 - y^2} = \sqrt{1 - (x^2 + y^2)} = \sqrt{1 - r^2}$. So this double integral can be converted to polar coordinates as

$$V = \iint_R (a + \sqrt{1 - x^2 - y^2}) \, dA = \int_0^{2\pi} \int_0^{\sqrt{1-a^2}} (a + \sqrt{1-r^2}) \cdot r \, dr \, d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^{\sqrt{1-a^2}} (a + \sqrt{1-r^2}) \cdot r \, dr$. In this integral we make a substitution $u = 1 - r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = 1 - 0^2 = 1$; if $r = \sqrt{1 - a^2}$, then $u = 1 - (\sqrt{1 - a^2})^2 = 1 - (1 - a^2) = a^2$.

So

$$\begin{aligned}
 \int_0^{\sqrt{1-a^2}} (a + \sqrt{1-r^2}) \cdot r \, dr &= \int_1^{a^2} (a + \sqrt{u}) \cdot \frac{du}{-2} = -\frac{1}{2} \int_1^{a^2} (a + \sqrt{u}) \, du \\
 &= \frac{1}{2} \int_{a^2}^1 (a + u^{1/2}) \, du = \frac{1}{2} \left[au + \frac{u^{3/2}}{3/2} \right]_{a^2}^1 = \left[\frac{1}{2} au + \frac{1}{3} (\sqrt{u})^3 \right]_{a^2}^1 \\
 &= \left[\frac{1}{2} a \cdot 1 + \frac{1}{3} (\sqrt{1})^3 \right] - \left[\frac{1}{2} a \cdot a^2 + \frac{1}{3} (\sqrt{a^2})^3 \right] \\
 &= \left(\frac{a}{2} + \frac{1}{3} \right) - \left(\frac{a^3}{2} + \frac{a^3}{3} \right) = \frac{a}{2} + \frac{1}{3} - \frac{a^3}{6} = \frac{2 + 3a - a^3}{6}.
 \end{aligned}$$

(Note that $\sqrt{a^2} = |a| = -a$, because $a \leq 0$.)

Going back to the iterated integral, the volume of the liquid is

$$\begin{aligned}
 V &= \int_0^{2\pi} \int_0^{\sqrt{1-a^2}} (a + \sqrt{1-r^2}) \cdot r \, dr \, d\theta = \int_0^{2\pi} \frac{2 + 3a - a^3}{6} \, d\theta \\
 &= \frac{2 + 3a - a^3}{6} \cdot [\theta]_0^{2\pi} = \frac{2 + 3a - a^3}{6} \cdot (2\pi - 0) = \boxed{\frac{(2 + 3a - a^3)\pi}{3} \text{ m}^3}.
 \end{aligned}$$

57. (a) Using the computer algebra system *Mathematica*, we can generate the graph of $r = \theta$, $0 \leq \theta \leq 2\pi$, shown in figure (a) below.

- (b) The region R bounded by the graph of $r = \theta$, $0 \leq \theta \leq 2\pi$, and the positive x -axis is shown in figure (b) above. In polar coordinates it can be described as $0 \leq r \leq \theta$, $0 \leq \theta \leq 2\pi$. So its area is

$$\begin{aligned}
 A &= \iint_R dA = \int_0^{2\pi} \int_0^\theta r \, dr \, d\theta = \int_0^{2\pi} \left[\frac{r^2}{2} \right]_0^\theta d\theta = \int_0^{2\pi} \left(\frac{\theta^2}{2} - \frac{0^2}{2} \right) d\theta \\
 &= \int_0^{2\pi} \frac{\theta^2}{2} d\theta = \left[\frac{\theta^3}{6} \right]_0^{2\pi} = \frac{(2\pi)^3}{6} - \frac{0^3}{6} = \frac{8\pi^3}{6} = \boxed{\frac{4\pi^3}{3} \text{ square units}}.
 \end{aligned}$$

58. The solid S cut from the sphere $x^2 + y^2 + z^2 = a^2$ by the cylinder $x^2 + y^2 = ay$, $a > 0$, is shown in figure (a) below. Notice that it is symmetric about the xy -plane, so we can find its volume if we find the volume of its upper half and multiply that by 2. This upper half is bounded from below by the plane $z = 0$, from above by the upper hemisphere $z = \sqrt{a^2 - x^2 - y^2}$, and it lies over the region R in the xy -plane bounded by the circle $x^2 + y^2 = ay$ or $r = a \sin \theta$; see figure (b) below.

Moreover, this region R and the part of the solid S above it are symmetric about the yz -plane, so we can find the volume of the quarter of the solid S lying over R to the right of the yz -plane and multiply that by 4. In polar coordinates, the equation of the upper hemisphere simplifies as $z = \sqrt{a^2 - x^2 - y^2} = \sqrt{a^2 - (x^2 + y^2)} = \sqrt{a^2 - r^2}$. The part of the region R to the right of the y -axis is given by $0 \leq r \leq a \sin \theta$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the volume is

$$V = 2 \iint_R \sqrt{a^2 - x^2 - y^2} dA = 4 \int_0^{\pi/2} \int_0^{a \sin \theta} \sqrt{a^2 - r^2} \cdot r dr d\theta.$$

(a)

(b)

In this iterated integral, first we evaluate the “inside” integral $\int_0^{a \sin \theta} \sqrt{a^2 - r^2} \cdot r dr$. In this integral we make a substitution $u = a^2 - r^2$; then $du = -2r dr$, so $r dr = -\frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = a^2 - 0^2 = a^2$; if $r = a \sin \theta$, then $u = a^2 - (a \sin \theta)^2 = a^2 - a^2 \sin^2 \theta = a^2(1 - \sin^2 \theta) = a^2 \cos^2 \theta$. So

$$\begin{aligned} \int_0^{a \sin \theta} \sqrt{a^2 - r^2} \cdot r dr &= \int_{a^2}^{a^2 \cos^2 \theta} \sqrt{u} \left(-\frac{du}{2} \right) = -\frac{1}{2} \int_{a^2}^{a^2 \cos^2 \theta} u^{1/2} du \\ &= \frac{1}{2} \int_{a^2 \cos^2 \theta}^{a^2} u^{1/2} du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_{a^2 \cos^2 \theta}^{a^2} = \frac{1}{3} \left[(\sqrt{u})^3 \right]_{a^2 \cos^2 \theta}^{a^2} \\ &= \frac{1}{3} \left[(\sqrt{a^2})^3 - (\sqrt{a^2 \cos^2 \theta})^3 \right] = \frac{1}{3} (a^3 - a^3 \cos^3 \theta) = \frac{a^3}{3} (1 - \cos^3 \theta), \end{aligned}$$

where we used the facts that $\sqrt{a^2} = a$ (because $a > 0$) and $\sqrt{\cos^2 \theta} = \cos \theta$ (because $0 \leq \theta \leq \frac{\pi}{2}$ and so $\cos \theta \geq 0$). Going back to the iterated integral,

$$\begin{aligned} V &= 4 \int_0^{\pi/2} \int_0^{a \sin \theta} \sqrt{a^2 - r^2} \cdot r dr d\theta = 4 \int_0^{\pi/2} \frac{a^3}{3} (1 - \cos^3 \theta) d\theta \\ &= \frac{4a^3}{3} \int_0^{\pi/2} (1 - \cos^3 \theta) d\theta = \frac{4a^3}{3} \int_0^{\pi/2} d\theta - \frac{4a^3}{3} \int_0^{\pi/2} \cos^3 \theta d\theta. \end{aligned}$$

The first integral can be evaluated directly:

$$\frac{4a^3}{3} \int_0^{\pi/2} d\theta = \frac{4a^3}{3} [\theta]_0^{\pi/2} = \frac{4a^3}{3} \left(\frac{\pi}{2} - 0 \right) = \frac{2a^3\pi}{3}.$$

To evaluate the second integral, we use a trigonometric identity to transform the integrand $\cos^3 \theta = \cos^2 \theta \cdot \cos \theta = (1 - \sin^2 \theta) \cos \theta$, and then make a substitution $v = \sin \theta$; then $dv = \cos \theta d\theta$. We also

change the limits of integration: if $\theta = 0$, then $v = \sin 0 = 0$; if $\theta = \frac{\pi}{2}$, then $v = \sin \frac{\pi}{2} = 1$. So

$$\begin{aligned} \frac{4a^3}{3} \int_0^{\pi/2} \cos^3 \theta \, d\theta &= \frac{4a^3}{3} \int_0^{\pi/2} (1 - \sin^2 \theta) \cos \theta \, d\theta = \frac{4a^3}{3} \int_0^1 (1 - v^2) \, dv \\ &= \frac{4a^3}{3} \left[v - \frac{v^3}{3} \right]_0^1 = \frac{4a^3}{3} \left[\left(1 - \frac{1}{3}\right) - (0 - 0) \right] = \frac{4a^3}{3} \cdot \frac{2}{3} = \frac{8a^3}{9}. \end{aligned}$$

Then the final answer is

$$V = \frac{4a^3}{3} \int_0^{\pi/2} d\theta - \frac{4a^3}{3} \int_0^{\pi/2} \cos^3 \theta \, d\theta = \frac{2a^3\pi}{3} - \frac{8a^3}{9} = \boxed{\frac{2a^3(3\pi - 4)}{9} \text{ cubic units}}.$$

59. We begin by graphing the rose curve $r = \sin(3\theta)$; see the figure below. Its leaf lying in the first quadrant, that is the region R shaded in the figure, is defined in polar coordinates by $0 \leq r \leq \sin(3\theta)$, $0 \leq \theta \leq \frac{\pi}{3}$. Then the area of this leaf can be found as

$$\begin{aligned} A &= \iint_R dA = \int_0^{\pi/3} \int_0^{\sin(3\theta)} r \, dr \, d\theta = \int_0^{\pi/3} \left[\frac{r^2}{2} \right]_0^{\sin(3\theta)} d\theta = \int_0^{\pi/3} \left(\frac{\sin^2(3\theta)}{2} - 0 \right) d\theta \\ &= \int_0^{\pi/3} \frac{1}{2} \sin^2(3\theta) \, d\theta = \int_0^{\pi/3} \frac{1}{2} \cdot \frac{1}{2} (1 - \cos(6\theta)) \, d\theta = \frac{1}{4} \left[\theta - \frac{1}{6} \sin(6\theta) \right]_0^{\pi/3} \\ &= \frac{1}{4} \left(\frac{\pi}{3} - \frac{1}{6} \sin(2\pi) \right) - \frac{1}{4} \left(0 - \frac{1}{6} \sin 0 \right) = \frac{1}{4} \left(\frac{\pi}{3} - 0 \right) - \frac{1}{4} (0 - 0) = \boxed{\frac{\pi}{12} \text{ square units}}. \end{aligned}$$

Challenge Problems

60. (a) In polar coordinates, $x = r \cos \theta$ and $\sqrt{x^2 + y^2} = r$, so

$$f(x, y) = \frac{1}{x^2 \sqrt{x^2 + y^2}} = \frac{1}{(r \cos \theta)^2 \cdot r} = \frac{1}{r^3 \cos^2 \theta} = \boxed{\frac{\sec^2 \theta}{r^3}}.$$

- (b) The region R defined by $1 \leq x \leq 2$, $0 \leq y \leq 1$ is a square region shown in figure (a) below. To represent it in polar coordinates, we draw three rays from the origin: along the positive x -axis — its equation is $\theta = 0$; through the corner of the square at $(2, 1)$ — since $\tan \theta = \frac{y}{x} = \frac{1}{2}$, its equation is $\theta = \tan^{-1} \left(\frac{1}{2} \right)$; and through the corner of the square at $(1, 1)$ — since $\tan \theta = \frac{y}{x} = \frac{1}{1} = 1$, its equation is $\theta = \tan^{-1} 1 = \frac{\pi}{4}$. These rays cut the region R into two subregions R_1 and R_2 ,

as shown in figure (b) below. The equations of the sides of the square can be converted to polar coordinates as follows:

$$\begin{array}{lll}
 x = 1 & x = 2 & y = 1 \\
 r \cos \theta = 1 & r \cos \theta = 2 & r \sin \theta = 1 \\
 r = \frac{1}{\cos \theta} & r = \frac{2}{\cos \theta} & r = \frac{1}{\sin \theta} \\
 r = \sec \theta & r = 2 \sec \theta & r = \csc \theta
 \end{array}$$

Then in polar coordinates the subregion R_1 can be described as $\sec \theta \leq r \leq 2 \sec \theta$, $0 \leq \theta \leq \tan^{-1} \left(\frac{1}{2} \right)$, and the subregion R_2 as $\sec \theta \leq r \leq \csc \theta$, $\tan^{-1} \left(\frac{1}{2} \right) \leq \theta \leq \frac{\pi}{4}$. Then, using the result of part (a), the given double integral can be converted to polar coordinates as follows:

$$\begin{aligned}
 \int_1^2 \int_0^1 \frac{1}{x^2 \sqrt{x^2 + y^2}} dy dx &= \iint_R \frac{1}{x^2 \sqrt{x^2 + y^2}} dA \\
 &= \iint_{R_1} \frac{1}{x^2 \sqrt{x^2 + y^2}} dA + \iint_{R_2} \frac{1}{x^2 \sqrt{x^2 + y^2}} dA \\
 &= \int_0^{\tan^{-1}(1/2)} \int_{\sec \theta}^{2 \sec \theta} \frac{\sec^2 \theta}{r^3} r dr d\theta + \int_{\tan^{-1}(1/2)}^{\pi/4} \int_{\sec \theta}^{\csc \theta} \frac{\sec^2 \theta}{r^3} r dr d\theta \\
 &= \int_0^{\tan^{-1}(1/2)} \int_{\sec \theta}^{2 \sec \theta} \frac{\sec^2 \theta}{r^2} dr d\theta + \int_{\tan^{-1}(1/2)}^{\pi/4} \int_{\sec \theta}^{\csc \theta} \frac{\sec^2 \theta}{r^2} dr d\theta \\
 &= \int_0^{\alpha} \int_{\sec \theta}^{2 \sec \theta} \frac{\sec^2 \theta}{r^2} dr d\theta + \int_{\alpha}^{\pi/4} \int_{\sec \theta}^{\csc \theta} \frac{\sec^2 \theta}{r^2} dr d\theta,
 \end{aligned}$$

where we denoted $\alpha = \tan^{-1} \left(\frac{1}{2} \right)$ for brevity.

The first integral evaluates as follows:

$$\begin{aligned}
 \int_0^{\alpha} \int_{\sec \theta}^{2 \sec \theta} \frac{\sec^2 \theta}{r^2} dr d\theta &= \int_0^{\alpha} \sec^2 \theta \left[\int_{\sec \theta}^{2 \sec \theta} r^{-2} dr \right] d\theta \\
 &= \int_0^{\alpha} \sec^2 \theta \left[\frac{r^{-1}}{-1} \right]_{\sec \theta}^{2 \sec \theta} d\theta = \int_0^{\alpha} \sec^2 \theta \left[-\frac{1}{r} \right]_{\sec \theta}^{2 \sec \theta} d\theta \\
 &= \int_0^{\alpha} \sec^2 \theta \left(-\frac{1}{2 \sec \theta} + \frac{1}{\sec \theta} \right) d\theta = \int_0^{\alpha} \sec^2 \theta \cdot \frac{1}{2 \sec \theta} d\theta \\
 &= \int_0^{\alpha} \frac{1}{2} \sec \theta d\theta = \frac{1}{2} [\ln |\sec \theta + \tan \theta|]_0^{\alpha} \\
 &= \frac{1}{2} \ln |\sec \alpha + \tan \alpha| - \frac{1}{2} \ln |\sec 0 + \tan 0| \\
 &= \frac{1}{2} \ln \left| \frac{\sqrt{5}}{2} + \frac{1}{2} \right| - \frac{1}{2} \ln |1 + 0| = \frac{1}{2} \ln \frac{\sqrt{5} + 1}{2} - \frac{1}{2} \cdot 0 = \frac{1}{2} \ln \frac{\sqrt{5} + 1}{2},
 \end{aligned}$$

where in the last line we substituted back $\alpha = \tan^{-1} \left(\frac{1}{2} \right)$, so $\tan \alpha = \frac{1}{2}$ and $\sec \alpha = \sqrt{1 + \tan^2 \alpha} =$

$$\sqrt{1 + \left(\frac{1}{2} \right)^2} = \sqrt{\frac{5}{4}} = \frac{\sqrt{5}}{2} \text{ (sec } \alpha \text{ is positive because } \alpha \text{ lies in the first quadrant).}$$

The second integral evaluates as follows:

$$\begin{aligned}
 \int_{\alpha}^{\pi/4} \int_{\sec \theta}^{\csc \theta} \frac{\sec^2 \theta}{r^2} dr d\theta &= \int_{\alpha}^{\pi/4} \sec^2 \theta \left[\int_{\sec \theta}^{\csc \theta} r^{-2} dr \right] d\theta \\
 &= \int_{\alpha}^{\pi/4} \sec^2 \theta \left[\frac{r^{-1}}{-1} \right]_{\sec \theta}^{\csc \theta} d\theta = \int_{\alpha}^{\pi/4} \sec^2 \theta \left[-\frac{1}{r} \right]_{\sec \theta}^{\csc \theta} d\theta \\
 &= \int_{\alpha}^{\pi/4} \sec^2 \theta \left(-\frac{1}{\csc \theta} + \frac{1}{\sec \theta} \right) d\theta = \int_{\alpha}^{\pi/4} \left(-\frac{\sec^2 \theta}{\csc \theta} + \sec \theta \right) d\theta \\
 &= \int_{\alpha}^{\pi/4} (\sec \theta - \tan \theta \sec \theta) d\theta = [\ln |\sec \theta + \tan \theta| - \sec \theta]_{\alpha}^{\pi/4} \\
 &= \left(\ln \left| \sec \frac{\pi}{4} + \tan \frac{\pi}{4} \right| - \sec \frac{\pi}{4} \right) - (\ln |\sec \alpha + \tan \alpha| - \sec \alpha) \\
 &= \left(\ln |\sqrt{2} + 1| - \sqrt{2} \right) - \left(\ln \left| \frac{\sqrt{5}}{2} + \frac{1}{2} \right| - \frac{\sqrt{5}}{2} \right) \\
 &= \ln(\sqrt{2} + 1) - \sqrt{2} - \ln \frac{\sqrt{5} + 1}{2} + \frac{\sqrt{5}}{2}.
 \end{aligned}$$

Adding the values of the two integrals, we obtain the final answer:

$$\begin{aligned}
 \int_1^2 \int_0^1 \frac{1}{x^2 \sqrt{x^2 + y^2}} dy dx &= \int_0^{\alpha} \int_{\sec \theta}^{2 \sec \theta} \frac{\sec^2 \theta}{r^2} dr d\theta + \int_{\alpha}^{\pi/4} \int_{\sec \theta}^{\csc \theta} \frac{\sec^2 \theta}{r^2} dr d\theta \\
 &= \left(\frac{1}{2} \ln \frac{\sqrt{5} + 1}{2} \right) + \left(\ln(\sqrt{2} + 1) - \sqrt{2} - \ln \frac{\sqrt{5} + 1}{2} + \frac{\sqrt{5}}{2} \right) \\
 &= \boxed{\frac{\sqrt{5}}{2} - \sqrt{2} - \frac{1}{2} \ln \frac{\sqrt{5} + 1}{2} + \ln(\sqrt{2} + 1)}.
 \end{aligned}$$

61. (a) Let $I_a = \int_0^a e^{-x^2} dx$. Since a definite integral is independent of the symbol used as the variable of integration, we can also write that $I_a = \int_0^a e^{-y^2} dy$. Then

$$\begin{aligned}
 I_a^2 &= \int_0^a e^{-x^2} dx \cdot \int_0^a e^{-y^2} dy = I_a \int_0^a e^{-y^2} dy = \int_0^a I_a e^{-y^2} dy = \int_0^a \left[\int_0^a e^{-x^2} dx \right] e^{-y^2} dy \\
 &= \int_0^a \left[\int_0^a e^{-x^2} e^{-y^2} dx \right] dy = \int_0^a \int_0^a e^{-x^2} e^{-y^2} dx dy = \int_0^a \int_0^a e^{-(x^2+y^2)} dx dy,
 \end{aligned}$$

where we used Fubini's Theorem for rectangular regions, the fact that I_a is a constant (it is a number), and that e^{-y^2} is constant with respect to x .

- (b) Let $J_a = \iint_R e^{-(x^2+y^2)} dA$, where R is the quarter circle $0 \leq r \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$. If R'' is the square $0 \leq x \leq a$, $0 \leq y \leq a$, and R' is the region lying inside the square R'' but outside the

quarter-circle R (see the figure below), then $I_a^2 = \iint_{R''} e^{-(x^2+y^2)} dA$ according to part (a), and by properties of double integrals

$$\begin{aligned} \iint_R e^{-(x^2+y^2)} dA + \iint_{R'} e^{-(x^2+y^2)} dA &= \iint_{R''} e^{-(x^2+y^2)} dA \\ J_a + \iint_{R'} e^{-(x^2+y^2)} dA &= I_a^2 \\ \iint_{R'} e^{-(x^2+y^2)} dA &= I_a^2 - J_a \end{aligned}$$

Notice that $I_a^2 - J_a$ is positive since it is equal to a double integral of a positive function.

Since the region R' lies outside the circle $x^2 + y^2 = a^2$, it follows that $x^2 + y^2 \geq a^2$ on R' , and therefore $e^{-(x^2+y^2)} \leq e^{-a^2}$ on R' . If we denote $f(x, y) = e^{-(x^2+y^2)}$ and $g(x, y) = e^{-a^2}$, then we have just demonstrated that $f(x, y) \leq g(x, y)$ on R' , and by the property proven in Problem 89, Section 14.2, $\iint_{R'} f(x, y) dA \leq \iint_{R'} g(x, y) dA$; that is

$$\begin{aligned} |I_a^2 - J_a| &= I_a^2 - J_a = \iint_{R'} e^{-(x^2+y^2)} dA \leq \iint_{R'} e^{-a^2} dA = e^{-a^2} \iint_{R'} dA \\ &= e^{-a^2} \cdot (\text{area of } R') = e^{-a^2} \cdot \left(a^2 - \frac{1}{4}\pi a^2 \right) = \frac{(4-\pi)a^2}{4} e^{-a^2}, \end{aligned}$$

where we found the area of R' by subtracting the area of the quarter-circle R from the area of the square R'' . So we have shown that

$$|I_a^2 - J_a| \leq \frac{(4-\pi)a^2}{4} e^{-a^2}.$$

(c) To find $J_a = \iint_R e^{-(x^2+y^2)} dA$, we convert it to polar coordinates:

$$J_a = \iint_R e^{-(x^2+y^2)} dA = \iint_R e^{-r^2} \cdot r dr d\theta = \int_0^{\pi/2} \int_0^a e^{-r^2} \cdot r dr d\theta.$$

In this iterated integral, first we evaluate the “inside” integral $\int_0^a e^{-r^2} \cdot r dr$. In this integral we make a substitution $u = -r^2$; then $du = -2rdr$, so $rdr = -\frac{du}{2}$. We also change the limits of integration: if $r = 0$, then $u = -0^2 = 0$; if $r = a$, then $u = -a^2$. So

$$\begin{aligned} \int_0^a e^{-r^2} \cdot r dr &= \int_0^{-a^2} e^u \left(-\frac{du}{2} \right) = -\frac{1}{2} \int_0^{-a^2} e^u du \\ &= \frac{1}{2} \int_{-a^2}^0 e^u du = \frac{1}{2} [e^u]_{-a^2}^0 = \frac{1}{2} (e^0 - e^{-a^2}) = \frac{1}{2} (1 - e^{-a^2}). \end{aligned}$$

Going back to the iterated integral,

$$\begin{aligned}\int_0^{\pi/2} \int_0^a e^{-r^2} \cdot r \, dr \, d\theta &= \int_0^{\pi/2} \frac{1}{2} (1 - e^{-a^2}) \, d\theta = \frac{1}{2} (1 - e^{-a^2}) \int_0^{\pi/2} d\theta \\ &= \frac{1}{2} (1 - e^{-a^2}) \cdot [\theta]_0^{\pi/2} = \frac{1}{2} (1 - e^{-a^2}) \cdot \left(\frac{\pi}{2} - 0\right) = \boxed{\frac{\pi}{4} (1 - e^{-a^2})}.\end{aligned}$$

- (d) Let $t = -a^2$. If $a \rightarrow \infty$, then $t = -a^2 \rightarrow -\infty$, and $\lim_{a \rightarrow \infty} e^{-a^2} = \lim_{t \rightarrow -\infty} e^t = 0$ by properties of the exponential function. Then

$$\lim_{a \rightarrow \infty} J_a = \lim_{a \rightarrow \infty} \frac{\pi}{4} (1 - e^{-a^2}) = \frac{\pi}{4} \lim_{a \rightarrow \infty} (1 - e^{-a^2}) = \frac{\pi}{4} \left(1 - \lim_{a \rightarrow \infty} e^{-a^2}\right) = \frac{\pi}{4} (1 - 0) = \frac{\pi}{4},$$

proving the first limit. Also,

$$\lim_{a \rightarrow \infty} \frac{(4 - \pi)a^2}{4} e^{-a^2} = \frac{4 - \pi}{4} \lim_{a \rightarrow \infty} \frac{a^2}{e^{a^2}} = \frac{4 - \pi}{4} \lim_{a \rightarrow \infty} \frac{2a}{2ae^{a^2}} = \frac{4 - \pi}{4} \lim_{a \rightarrow \infty} \frac{1}{e^{a^2}} = 0,$$

where we applied L'Hospital's rule at the second step. Since according to part (b), $0 \leq |I_a^2 - J_a| \leq \frac{(4 - \pi)a^2}{4} e^{-a^2}$, and $\lim_{a \rightarrow \infty} 0 = \lim_{a \rightarrow \infty} \frac{(4 - \pi)a^2}{4} e^{-a^2} = 0$ as shown above, then by the Squeeze Theorem, $\lim_{a \rightarrow \infty} |I_a^2 - J_a| = 0$, proving the second limit.

- (e) First, using the results of part (d), we can find the limit of I_a as $a \rightarrow \infty$: $\lim_{a \rightarrow \infty} |I_a^2 - J_a| = 0$ is equivalent to $\lim_{a \rightarrow \infty} (I_a^2 - J_a) = 0$, and so

$$\lim_{a \rightarrow \infty} I_a^2 = \lim_{a \rightarrow \infty} [J_a + (I_a^2 - J_a)] = \lim_{a \rightarrow \infty} J_a + \lim_{a \rightarrow \infty} (I_a^2 - J_a) = \frac{\pi}{4} + 0 = \frac{\pi}{4},$$

which implies that $\lim_{a \rightarrow \infty} I_a = \sqrt{\frac{\pi}{4}} = \frac{\sqrt{\pi}}{2}$.

Now we can find the improper integral $\int_0^\infty e^{-x^2} dx$:

$$\int_0^\infty e^{-x^2} dx = \lim_{a \rightarrow \infty} \int_0^a e^{-x^2} dx = \lim_{a \rightarrow \infty} I_a = \frac{\sqrt{\pi}}{2}.$$

Since e^{-x^2} is an even function, for any $a > 0$, $\int_{-a}^0 e^{-x^2} dx = \int_0^a e^{-x^2} dx$ by properties of definite integrals, and therefore

$$\int_{-\infty}^0 e^{-x^2} dx = \lim_{a \rightarrow \infty} \int_{-a}^0 e^{-x^2} dx = \lim_{a \rightarrow \infty} \int_0^a e^{-x^2} dx = \frac{\sqrt{\pi}}{2}.$$

Adding these together, we obtain that

$$\int_{-\infty}^\infty e^{-x^2} dx = \int_{-\infty}^0 e^{-x^2} dx + \int_0^\infty e^{-x^2} dx = \frac{\sqrt{\pi}}{2} + \frac{\sqrt{\pi}}{2} = \sqrt{\pi}.$$

14.4 Center of Mass; Moment of Inertia

Concepts and Vocabulary

1. If a lamina is represented by a closed bounded region R and has a continuous mass density function $\rho(x, y)$, then the double integral $\iint_R \rho(x, y) dA$ gives the mass of the lamina.
2. False. If a lamina is represented by a closed bounded region R and has a continuous mass density function $\rho(x, y)$, then $\iint_R y\rho(x, y) dA = M_x$, the moment of mass about the x -axis. The moment of mass about the y -axis is given by $M_y = \iint_R x\rho(x, y) dA$.
3. If a lamina is represented by a closed bounded region R and has a continuous mass density function $\rho(x, y)$, then the moment of mass about the y -axis is given by the double integral $M_y = \iint_R x\rho(x, y) dA$.
4. False. The centroid is a geometrical property of a lamina; it coincides with the center of mass in the case of a homogeneous lamina (when the mass density is constant). The center of mass is a physical property of a lamina, and if the mass density is variable, it may not be at the geometrical center (centroid) of the lamina.
5. True. If a particle of mass m is located a distance d from a fixed axis a , the moment of mass of the particle about the a -axis is $M_a = md$, and it measures the tendency of the particle to rotate about this axis.
6. False. The moment of inertia about the origin equals the sum of the moment of inertia about the x -axis and the moment of inertia about the y -axis.

Skill Building

7. The lamina occupies the triangular region R shown in the figure in Problem 7, see also the figure below. The side of the triangle joining the points $(0, 0)$ and $(3, 6)$ has the equation $y = 2x$. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 2x$, $0 \leq x \leq 3$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R x^2 y dA = \int_0^3 \int_0^{2x} x^2 y dy dx = \int_0^3 x^2 \left[\frac{y^2}{2} \right]_0^{2x} dx \\ &= \int_0^3 x^2 (2x^2 - 0) dx = \int_0^3 2x^4 dx = 2 \left[\frac{x^5}{5} \right]_0^3 = 2 \left(\frac{243}{5} - 0 \right) = \frac{486}{5}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x \cdot x^2 y dA = \int_0^3 \int_0^{2x} x^3 y dy dx = \int_0^3 x^3 \left[\frac{y^2}{2} \right]_0^{2x} dx \\ &= \int_0^3 x^3 (2x^2 - 0) dx = \int_0^3 2x^5 dx = \left[\frac{x^6}{3} \right]_0^3 = \frac{3^6}{3} - 0 = 243, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{243}{486/5} = \frac{5}{2}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R y \cdot x^2 y dA = \int_0^3 \int_0^{2x} x^2 y^2 dy dx = \int_0^3 x^2 \left[\frac{y^3}{3} \right]_0^{2x} dx \\ &= \int_0^3 x^2 \left(\frac{8x^3}{3} - 0 \right) dx = \int_0^3 \frac{8x^5}{3} dx = \left[\frac{4x^6}{9} \right]_0^3 = \frac{4 \cdot 3^6}{9} - 0 = 324, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{324}{486/5} = \frac{10}{3}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{5}{2}, \frac{10}{3} \right)$.

8. The lamina occupies the square region R shown in the figure in Problem 8; see also the figure below. Notice that R is an x -simple region: it is bounded between $y = 1$ and $y = 4$, $1 \leq x \leq 4$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R xy^2 dA = \int_1^4 \int_1^4 xy^2 dy dx = \int_1^4 x \left[\frac{y^3}{3} \right]_1^4 dx \\ &= \int_1^4 x \left(\frac{64}{3} - \frac{1}{3} \right) dx = \int_1^4 21x dx = 21 \left[\frac{x^2}{2} \right]_1^4 = 21 \left(8 - \frac{1}{2} \right) = 21 \cdot \frac{15}{2} = \boxed{\frac{315}{2}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x \cdot xy^2 dA = \int_1^4 \int_1^4 x^2 y^2 dy dx = \int_1^4 x^2 \left[\frac{y^3}{3} \right]_1^4 dx \\ &= \int_1^4 x^2 \left(\frac{64}{3} - \frac{1}{3} \right) dx = \int_1^4 21x^2 dx = [7x^3]_1^4 = 7(64 - 1) = 441, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{441}{315/2} = \frac{14}{5}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R y \cdot xy^2 dA = \int_1^4 \int_1^4 xy^3 dy dx = \int_1^4 x \left[\frac{y^4}{4} \right]_1^4 dx \\ &= \int_1^4 x \left(64 - \frac{1}{4} \right) dx = \int_1^4 \frac{255x}{4} dx = \left[\frac{255x^2}{8} \right]_1^4 = 510 - \frac{255}{8} = \frac{3825}{8}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{3825/8}{315/2} = \frac{85}{28}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{14}{5}, \frac{85}{28} \right)$.

9. The region R enclosed by the lines $x = 2$ and $y = 4$ and the coordinate axes is a rectangle, as shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 4$, $0 \leq x \leq 2$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R 3x^2 y dA = \int_0^2 \int_0^4 3x^2 y dy dx = \int_0^2 3x^2 \left[\frac{y^2}{2} \right]_0^4 dx \\ &= \int_0^2 3x^2 (8 - 0) dx = \int_0^2 24x^2 dx = [8x^3]_0^2 = 8(8 - 0) = \boxed{64}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x \rho(x, y) dA = \iint_R x \cdot 3x^2 y dA = \int_0^2 \int_0^4 3x^3 y dy dx = \int_0^2 3x^3 \left[\frac{y^2}{2} \right]_0^4 dx \\ &= \int_0^2 3x^3 (8 - 0) dx = \int_0^2 24x^3 dx = [6x^4]_0^2 = 6(16 - 0) = 96, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{96}{64} = \frac{3}{2}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) dA = \iint_R y \cdot 3x^2 y dA = \int_0^2 \int_0^4 3x^2 y^2 dy dx = \int_0^2 x^2 [y^3]_0^4 dx \\ &= \int_0^2 x^2 (64 - 0) dx = \int_0^2 64x^2 dx = \left[\frac{64x^3}{3} \right]_0^2 = \frac{512}{3} - 0 = \frac{512}{3}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{512/3}{64} = \frac{8}{3}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{3}{2}, \frac{8}{3} \right)$.

10. The region R enclosed by the lines $x = 1$ and $y = 2$ and the coordinate axes is a rectangle, as shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 2$, $0 \leq x \leq 1$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R 2x^2 y^2 dA = \int_0^1 \int_0^2 2x^2 y^2 dy dx = \int_0^1 2x^2 \left[\frac{y^3}{3} \right]_0^2 dx \\ &= \int_0^1 2x^2 \left(\frac{8}{3} - 0 \right) dx = \int_0^1 \frac{16x^2}{3} dx = \left[\frac{16x^3}{9} \right]_0^1 = \frac{16}{9} - 0 = \boxed{\frac{16}{9}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x \rho(x, y) dA = \iint_R x \cdot 2x^2 y^2 dA = \int_0^1 \int_0^2 2x^3 y^2 dy dx = \int_0^1 2x^3 \left[\frac{y^3}{3} \right]_0^2 dx \\ &= \int_0^1 2x^3 \left(\frac{8}{3} - 0 \right) dx = \int_0^1 \frac{16x^3}{3} dx = \left[\frac{4x^4}{3} \right]_0^1 = \frac{4}{3} - 0 = \frac{4}{3}, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{4/3}{16/9} = \frac{3}{4}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) dA = \iint_R y \cdot 2x^2 y^2 dA = \int_0^1 \int_0^2 2x^2 y^3 dy dx = \int_0^1 2x^2 \left[\frac{y^4}{4} \right]_0^2 dx \\ &= \int_0^1 2x^2 (4 - 0) dx = \int_0^1 8x^2 dx = \left[\frac{8x^3}{3} \right]_0^1 = \frac{8}{3} - 0 = \frac{8}{3}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{8/3}{16/9} = \frac{3}{2}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \boxed{\left(\frac{3}{4}, \frac{3}{2} \right)}$.

11. The region R enclosed in the first quadrant by $y^2 = x$, $x = 1$, and the x -axis is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = \sqrt{x}$, $0 \leq x \leq 1$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R (2x + 3y) dA = \int_0^1 \int_0^{\sqrt{x}} (2x + 3y) dy dx = \int_0^1 \left[2xy + \frac{3y^2}{2} \right]_0^{\sqrt{x}} dx \\
 &= \int_0^1 \left[2x\sqrt{x} + \frac{3(\sqrt{x})^2}{2} \right] - (0 + 0) dx = \int_0^1 \left(2x^{3/2} + \frac{3}{2}x \right) dx = \left[2 \cdot \frac{x^{5/2}}{5/2} + \frac{3}{2} \cdot \frac{x^2}{2} \right]_0^1 \\
 &= \left[\frac{4}{5}x^{5/2} + \frac{3}{4}x^2 \right]_0^1 = \left(\frac{4}{5} + \frac{3}{4} \right) - (0 + 0) = \boxed{\frac{31}{20}}.
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R x(2x + 3y) dA = \int_0^1 \int_0^{\sqrt{x}} (2x^2 + 3xy) dy dx \\
 &= \int_0^1 \left[2x^2y + \frac{3xy^2}{2} \right]_0^{\sqrt{x}} dx = \int_0^1 \left[2x^2\sqrt{x} + \frac{3x(\sqrt{x})^2}{2} \right] - (0 + 0) dx \\
 &= \int_0^1 \left(2x^{5/2} + \frac{3}{2}x^2 \right) dx = \left[2 \cdot \frac{x^{7/2}}{7/2} + \frac{3}{2} \cdot \frac{x^3}{3} \right]_0^1 \\
 &= \left[\frac{4}{7}x^{7/2} + \frac{1}{2}x^3 \right]_0^1 = \left(\frac{4}{7} + \frac{1}{2} \right) - (0 + 0) = \frac{15}{14},
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{15/14}{31/20} = \frac{150}{217}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x, y) dA = \iint_R y(2x + 3y) dA = \int_0^1 \int_0^{\sqrt{x}} (2xy + 3y^2) dy dx \\
 &= \int_0^1 \left[xy^2 + y^3 \right]_0^{\sqrt{x}} dx = \int_0^1 \left[(x(\sqrt{x})^2 + (\sqrt{x})^3) - (0 + 0) \right] dx = \int_0^1 (x^2 + x^{3/2}) dx \\
 &= \left[\frac{x^3}{3} + \frac{x^{5/2}}{5/2} \right]_0^1 = \left[\frac{1}{3}x^3 + \frac{2}{5}x^{5/2} \right]_0^1 = \left(\frac{1}{3} + \frac{2}{5} \right) - (0 + 0) = \frac{11}{15},
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{11/15}{31/20} = \frac{44}{93}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{150}{217}, \frac{44}{93} \right)$.

12. The region R enclosed in the first quadrant by $y^2 = 4x$, $x = 1$, and the x -axis is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 2\sqrt{x}$, $0 \leq x \leq 1$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R (x+1) dA = \int_0^1 \int_0^{2\sqrt{x}} (x+1) dy dx = \int_0^1 [(x+1)y]_0^{2\sqrt{x}} dx \\ &= \int_0^1 [(x+1) \cdot 2\sqrt{x} - (x+1) \cdot 0] dx = \int_0^1 (2x^{3/2} + 2x^{1/2}) dx = \left[2 \cdot \frac{x^{5/2}}{5/2} + 2 \cdot \frac{x^{3/2}}{3/2} \right]_0^1 \\ &= \left[\frac{4}{5}x^{5/2} + \frac{4}{3}x^{3/2} \right]_0^1 = \left(\frac{4}{5} + \frac{4}{3} \right) - (0+0) = \boxed{\frac{32}{15}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x(x+1) dA = \int_0^1 \int_0^{2\sqrt{x}} (x^2 + x) dy dx = \int_0^1 [(x^2 + x)y]_0^{2\sqrt{x}} dx \\ &= \int_0^1 [(x^2 + x) \cdot 2\sqrt{x} - (x+1) \cdot 0] dx = \int_0^1 (2x^{5/2} + 2x^{3/2}) dx = \left[2 \cdot \frac{x^{7/2}}{7/2} + 2 \cdot \frac{x^{5/2}}{5/2} \right]_0^1 \\ &= \left[\frac{4}{7}x^{7/2} + \frac{4}{5}x^{5/2} \right]_0^1 = \left(\frac{4}{7} + \frac{4}{5} \right) - (0+0) = \frac{48}{35}, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{48/35}{32/15} = \frac{9}{14}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R y(x+1) dA = \int_0^1 \int_0^{2\sqrt{x}} (x+1)y dy dx = \int_0^1 \left[(x+1)\frac{y^2}{2} \right]_0^{2\sqrt{x}} dx \\ &= \int_0^1 [(x+1) \cdot 2x - (x+1) \cdot 0] dx = \int_0^1 (2x^2 + 2x) dx = \left[\frac{2}{3}x^3 + x^2 \right]_0^1 \\ &= \left(\frac{2}{3} + 1 \right) - (0+0) = \frac{5}{3}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{5/3}{32/15} = \frac{25}{32}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{9}{14}, \frac{25}{32} \right)$.

13. The region R enclosed by $y^2 = x$ and $y = x$ is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = x$ and $y = \sqrt{x}$, $0 \leq x \leq 1$. The mass density of the lamina is proportional to the distance from the y -axis; that is, $\rho(x, y) = kx$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R kx dA = k \int_0^1 \int_x^{\sqrt{x}} x dy dx = k \int_0^1 [xy]_x^{\sqrt{x}} dx \\
 &= k \int_0^1 [x \cdot \sqrt{x} - x \cdot x] dx = k \int_0^1 (x^{3/2} - x^2) dx = k \left[\frac{x^{5/2}}{5/2} - \frac{x^3}{3} \right]_0^1 \\
 &= k \left[\frac{2}{5} x^{5/2} - \frac{1}{3} x^3 \right]_0^1 = k \left[\left(\frac{2}{5} - \frac{1}{3} \right) - (0 - 0) \right] = \frac{1}{15} k \\
 &= \boxed{\frac{k}{15}}, \text{ where } k \text{ is the constant of proportionality.}
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x \rho(x, y) dA = \iint_R x \cdot kx dA = k \int_0^1 \int_x^{\sqrt{x}} x^2 dy dx = k \int_0^1 [x^2 y]_x^{\sqrt{x}} dx \\
 &= k \int_0^1 [x^2 \cdot \sqrt{x} - x^2 \cdot x] dx = k \int_0^1 (x^{5/2} - x^3) dx = k \left[\frac{x^{7/2}}{7/2} - \frac{x^4}{4} \right]_0^1 \\
 &= k \left[\frac{2}{7} x^{7/2} - \frac{1}{4} x^4 \right]_0^1 = k \left[\left(\frac{2}{7} - \frac{1}{4} \right) - (0 - 0) \right] = \frac{1}{28} k,
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{(1/28)k}{(1/15)k} = \frac{15}{28}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y \rho(x, y) dA = \iint_R y \cdot kx dA = k \int_0^1 \int_x^{\sqrt{x}} xy dy dx = k \int_0^1 \left[x \frac{y^2}{2} \right]_x^{\sqrt{x}} dx \\
 &= k \int_0^1 \left[x \cdot \frac{x}{2} - x \cdot \frac{x^2}{2} \right] dx = k \int_0^1 \left(\frac{1}{2} x^2 - \frac{1}{2} x^3 \right) dx = k \left[\frac{1}{6} x^3 - \frac{1}{8} x^4 \right]_0^1 \\
 &= k \left[\left(\frac{1}{6} - \frac{1}{8} \right) - (0 - 0) \right] = \frac{1}{24} k,
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{(1/24)k}{(1/15)k} = \frac{5}{8}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{15}{28}, \frac{5}{8} \right)$.

14. The region R enclosed by $y = \sin x$ and the x -axis, $0 \leq x \leq \pi$, is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = \sin x$, $0 \leq x \leq \pi$. The mass density of the lamina is proportional to the distance from the x -axis; that is, $\rho(x, y) = ky$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R ky dA = k \int_0^\pi \int_0^{\sin x} y dy dx = k \int_0^\pi \left[\frac{y^2}{2} \right]_0^{\sin x} dx \\ &= k \int_0^\pi \left[\frac{(\sin x)^2}{2} - 0 \right] dx = \frac{k}{2} \int_0^\pi \sin^2 x dx = \frac{k}{2} \int_0^\pi \frac{1}{2} (1 - \cos(2x)) dx = \frac{k}{4} \left[x - \frac{1}{2} \sin(2x) \right]_0^\pi \\ &= \frac{k}{4} \left[\left(\pi - \frac{1}{2} \sin(2\pi) \right) - \left(0 - \frac{1}{2} \sin(0) \right) \right] = \frac{k}{4} [(\pi - 0) - (0 - 0)] \\ &= \boxed{\frac{k\pi}{4}, \text{ where } k \text{ is the constant of proportionality.}} \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x \cdot ky dA = k \int_0^\pi \int_0^{\sin x} xy dy dx = k \int_0^\pi x \left[\frac{y^2}{2} \right]_0^{\sin x} dx \\ &= k \int_0^\pi x \left[\frac{(\sin x)^2}{2} - 0 \right] dx = \frac{k}{2} \int_0^\pi x \sin^2 x dx = \frac{k}{2} \int_0^\pi x \cdot \frac{1}{2} (1 - \cos(2x)) dx \\ &= \frac{k}{4} \int_0^\pi (x - x \cos(2x)) dx = \frac{k}{4} \left[\int_0^\pi x dx - \int_0^\pi x \cos(2x) dx \right]. \end{aligned}$$

The first integral in the brackets can be evaluated directly:

$$\int_0^\pi x dx = \left[\frac{x^2}{2} \right]_0^\pi = \frac{\pi^2}{2} - \frac{0^2}{2} = \frac{\pi^2}{2}.$$

To evaluate the second integral in the brackets, we use the method of integration by parts. If we choose $u = x$ and $dv = \cos(2x) dx$, then $du = dx$ and $v = \int \cos(2x) dx = \frac{1}{2} \sin(2x)$. So

$$\begin{aligned} \int_0^\pi x \cos(2x) dx &= \left[x \cdot \frac{1}{2} \sin(2x) \right]_0^\pi - \int_0^\pi \frac{1}{2} \sin(2x) dx = \left(\frac{1}{2} \cdot \pi \sin(2\pi) - \frac{1}{2} \cdot 0 \sin(0) \right) + \left[\frac{1}{4} \cos(2x) \right]_0^\pi \\ &= (0 - 0) + \left(\frac{1}{4} \cos(2\pi) - \frac{1}{4} \cos(0) \right) = 0 + \left(\frac{1}{4} - \frac{1}{4} \right) = 0. \end{aligned}$$

Substituting these values back into the computation of M_y , we obtain

$$M_y = \frac{k}{4} \left[\int_0^\pi x \, dx - \int_0^\pi x \cos(2x) \, dx \right] = \frac{k}{4} \left[\frac{\pi^2}{2} - 0 \right] = \frac{k\pi^2}{8},$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{k\pi^2/8}{k\pi/4} = \frac{\pi}{2}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) \, dA = \iint_R y \cdot ky \, dA = k \int_0^\pi \int_0^{\sin x} y^2 \, dy \, dx = k \int_0^\pi \left[\frac{y^3}{3} \right]_0^{\sin x} dx \\ &= k \int_0^\pi \left[\frac{(\sin x)^3}{3} - 0 \right] dx = \frac{k}{3} \int_0^\pi \sin^3 x \, dx = \frac{k}{3} \int_0^\pi \sin^2 x \sin x \, dx = \frac{k}{3} \int_0^\pi (1 - \cos^2 x) \sin x \, dx. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos x$; then $du = -\sin x \, dx$, so $\sin x \, dx = -du$. We also change the limits of integration: if $x = 0$, then $u = \cos 0 = 1$; if $x = \pi$, then $u = \cos \pi = -1$. So

$$\begin{aligned} M_x &= \frac{k}{3} \int_0^\pi (1 - \cos^2 x) \sin x \, dx = \frac{k}{3} \int_1^{-1} (1 - u^2)(-du) = -\frac{k}{3} \int_1^{-1} (1 - u^2) \, du \\ &= \frac{k}{3} \int_{-1}^1 (1 - u^2) \, du = \frac{k}{3} \left[u - \frac{u^3}{3} \right]_{-1}^1 = \frac{k}{3} \left[\left(1 - \frac{1}{3}\right) - \left(-1 - \frac{-1}{3}\right) \right] \\ &= \frac{k}{3} \left[\frac{2}{3} - \left(-\frac{2}{3}\right) \right] = \frac{k}{3} \cdot \frac{4}{3} = \frac{4k}{9}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{4k/9}{k\pi/4} = \frac{16}{9\pi}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{\pi}{2}, \frac{16}{9\pi} \right)$.

15. The region R enclosed by the lines $2x + 3y = 6$, $x = 0$ (the y -axis), and $y = 0$ (the x -axis) is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 2 - \frac{2x}{3}$, $0 \leq x \leq 3$. The mass density of the lamina is proportional to the sum of the distances from the coordinate axes; that is, $\rho(x, y) = k(x + y)$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) \, dA = \iint_R k(x + y) \, dA = k \int_0^3 \int_0^{2-2x/3} (x + y) \, dy \, dx = k \int_0^3 \left[xy + \frac{y^2}{2} \right]_0^{2-2x/3} dx \\ &= k \int_0^3 \left\{ x \left(2 - \frac{2x}{3} \right) + \frac{\left(2 - \frac{2x}{3} \right)^2}{2} \right\} - (0 + 0) \, dx = k \int_0^3 \left(2x - \frac{2x^2}{3} + 2 - \frac{4x}{3} + \frac{2x^2}{9} \right) dx \\ &= k \int_0^3 \left(2 + \frac{2x}{3} - \frac{4x^2}{9} \right) dx = k \left[2x + \frac{x^2}{3} - \frac{4x^3}{27} \right]_0^3 = k[(6 + 3 - 4) - (0 + 0 - 0)] \\ &= \boxed{5k, \text{ where } k \text{ is the constant of proportionality}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x,y) dA = \iint_R x \cdot k(x+y) dA = k \int_0^3 \int_0^{2-2x/3} (x^2 + xy) dy dx \\
 &= k \int_0^3 \left[x^2 y + x \frac{y^2}{2} \right]_0^{2-2x/3} dx = k \int_0^3 \left\{ \left[x^2 \left(2 - \frac{2x}{3} \right) + x \frac{\left(2 - \frac{2x}{3} \right)^2}{2} \right] - (0+0) \right\} dx \\
 &= k \int_0^3 \left(2x^2 - \frac{2x^3}{3} + 2x - \frac{4x^2}{3} + \frac{2x^3}{9} \right) dx = k \int_0^3 \left(2x + \frac{2x^2}{3} - \frac{4x^3}{9} \right) dx \\
 &= k \left[x^2 + \frac{2x^3}{9} - \frac{x^4}{9} \right]_0^3 = k [(9+6-9) - (0+0-0)] = 6k,
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{6k}{5k} = \frac{6}{5} = 1.2.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x,y) dA = \iint_R y \cdot k(x+y) dA = k \int_0^3 \int_0^{2-2x/3} (xy + y^2) dy dx \\
 &= k \int_0^3 \left[x \frac{y^2}{2} + \frac{y^3}{3} \right]_0^{2-2x/3} dx = k \int_0^3 \left\{ \left[x \frac{\left(2 - \frac{2x}{3} \right)^2}{2} + \frac{\left(2 - \frac{2x}{3} \right)^3}{3} \right] - (0+0) \right\} dx \\
 &= k \int_0^3 \left(2x - \frac{4x^2}{3} + \frac{2x^3}{9} + \frac{8}{3} - \frac{8x}{3} + \frac{8x^2}{9} - \frac{8x^3}{81} \right) dx = k \int_0^3 \left(\frac{8}{3} - \frac{2x}{3} - \frac{4x^2}{9} + \frac{10x^3}{81} \right) dx \\
 &= k \left[\frac{8x}{3} - \frac{x^2}{3} - \frac{4x^3}{27} + \frac{5x^4}{162} \right]_0^3 = k \left[\left(8 - 3 - 4 + \frac{5}{2} \right) - (0 - 0 - 0 + 0) \right] = \frac{7}{2}k,
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{(7/2)k}{5k} = \frac{7}{10} = 0.7.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{6}{5}, \frac{7}{10} \right) = (1.2, 0.7)$.

16. The region R enclosed by the lines $3x + 4y = 12$, $x = 0$ (the y -axis), and $y = 0$ (the x -axis) is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 3 - \frac{3x}{4}$, $0 \leq x \leq 4$. The mass density of the lamina is proportional to the product of the distances from the coordinate axes; that is, $\rho(x,y) = kxy$, where k is a constant coefficient of proportionality. Then the

mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R kxy dA = k \int_0^4 \int_0^{3-3x/4} xy dy dx = k \int_0^4 \left[x \frac{y^2}{2} \right]_0^{3-3x/4} dx \\
 &= k \int_0^4 \left[x \frac{\left(3 - \frac{3x}{4}\right)^2}{2} - 0 \right] dx = k \int_0^4 \left(\frac{9x}{2} - \frac{9x^2}{4} + \frac{9x^3}{32} \right) dx \\
 &= k \left[\frac{9x^2}{4} - \frac{3x^3}{4} + \frac{9x^4}{128} \right]_0^4 = k [(36 - 48 + 18) - (0 - 0 + 0)] = \\
 &= \boxed{6k, \text{ where } k \text{ is the constant of proportionality}}.
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R x \cdot kxy dA = k \int_0^4 \int_0^{3-3x/4} x^2 y dy dx = k \int_0^4 \left[x^2 \frac{y^2}{2} \right]_0^{3-3x/4} dx \\
 &= k \int_0^4 \left[x^2 \frac{\left(3 - \frac{3x}{4}\right)^2}{2} - 0 \right] dx = k \int_0^4 \left(\frac{9x^2}{2} - \frac{9x^3}{4} + \frac{9x^4}{32} \right) dx \\
 &= k \left[\frac{3x^3}{2} - \frac{9x^4}{16} + \frac{9x^5}{160} \right]_0^4 = k \left[\left(96 - 144 + \frac{288}{5} \right) - (0 - 0 + 0) \right] = \frac{48}{5}k,
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{(48/5)k}{6k} = \frac{8}{5} = 1.6.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x, y) dA = \iint_R y \cdot kxy dA = k \int_0^4 \int_0^{3-3x/4} xy^2 dy dx = k \int_0^4 \left[x \frac{y^3}{3} \right]_0^{3-3x/4} dx \\
 &= k \int_0^4 \left[x \frac{\left(3 - \frac{3x}{4}\right)^3}{3} - 0 \right] dx = k \int_0^4 \left(9x - \frac{27x^2}{4} + \frac{27x^3}{16} - \frac{9x^4}{64} \right) dx \\
 &= k \left[\frac{9x^2}{2} - \frac{9x^3}{4} + \frac{27x^4}{64} - \frac{9x^5}{320} \right]_0^4 = k \left[\left(72 - 144 + 108 - \frac{144}{5} \right) - (0 - 0 + 0 - 0) \right] = \frac{36}{5}k,
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{(36/5)k}{6k} = \frac{6}{5} = 1.2.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \boxed{\left(\frac{8}{5}, \frac{6}{5} \right) = (1.6, 1.2)}$.

17. The region R enclosed by the cardioid $r = 1 + \sin \theta$ is shown in the figure below. In polar coordinates, it is given by $0 \leq r \leq 1 + \sin \theta$, $0 \leq \theta \leq 2\pi$. The mass density of the lamina is proportional to the distance from the pole; that is, $\rho(r, \theta) = kr$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R kr \cdot r dr d\theta = k \int_0^{2\pi} \int_0^{1+\sin \theta} r^2 dr d\theta = k \int_0^{2\pi} \left[\frac{r^3}{3} \right]_0^{1+\sin \theta} d\theta \\
 &= k \int_0^{2\pi} \left[\frac{1}{3}(1 + \sin \theta)^3 - 0 \right] d\theta = k \int_0^{2\pi} \left(\frac{1}{3} + \sin \theta + \sin^2 \theta + \frac{1}{3} \sin^3 \theta \right) d\theta \\
 &= k \int_0^{2\pi} \left(\frac{1}{3} + \sin \theta + \frac{1}{2}(1 - \cos(2\theta)) + \frac{1}{3} \sin^3 \theta \right) d\theta = k \int_0^{2\pi} \left(\frac{5}{6} + \sin \theta - \frac{1}{2} \cos(2\theta) + \frac{1}{3} \sin^3 \theta \right) d\theta \\
 &= k \left(\frac{5}{6} \int_0^{2\pi} d\theta + \int_0^{2\pi} \sin \theta d\theta - \frac{1}{2} \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{3} \int_0^{2\pi} \sin^3 \theta d\theta \right).
 \end{aligned}$$

The first three integrals in parentheses can be evaluated directly:

$$\begin{aligned}
 \frac{5}{6} \int_0^{2\pi} d\theta &= \frac{5}{6} [\theta]_0^{2\pi} = \frac{5}{6} (2\pi - 0) = \frac{5\pi}{3}; \\
 \int_0^{2\pi} \sin \theta d\theta &= [-\cos \theta]_0^{2\pi} = -\cos 2\pi + \cos 0 = -1 + 1 = 0; \\
 \frac{1}{2} \int_0^{2\pi} \cos(2\theta) d\theta &= \frac{1}{2} \left[\frac{\sin(2\theta)}{2} \right]_0^{2\pi} = \frac{1}{4} [\sin(2\theta)]_0^{2\pi} = \frac{1}{4} (\sin(4\pi) - \sin 0) = \frac{1}{4} (0 - 0) = 0.
 \end{aligned}$$

To evaluate the last integral in parentheses, we use a trigonometric identity to transform the integrand $\sin^3 \theta = \sin^2 \theta \cdot \sin \theta = (1 - \cos^2 \theta) \sin \theta$, and then make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = 0$, then $u = \cos 0 = 1$; if $\theta = 2\pi$, then $u = \cos 2\pi = 1$. So

$$\frac{1}{3} \int_0^{2\pi} \sin^3 \theta d\theta = \frac{1}{3} \int_0^{2\pi} (1 - \cos^2 \theta) \sin \theta d\theta = \frac{1}{3} \int_1^1 (1 - u^2)(-du) = -\frac{1}{3} \int_1^1 (1 - u^2) du = 0.$$

Substituting these values back into the computation of M , we obtain

$$\begin{aligned}
 M &= k \left(\frac{5}{6} \int_0^{2\pi} d\theta + \int_0^{2\pi} \sin \theta d\theta - \frac{1}{2} \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{3} \int_0^{2\pi} \sin^3 \theta d\theta \right) = k \left(\frac{5\pi}{3} + 0 - 0 + 0 \right) \\
 &= \boxed{\frac{5\pi k}{3}}, \text{ where } k \text{ is the constant of proportionality.}
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R r \cos \theta \cdot kr \cdot r dr d\theta = k \int_0^{2\pi} \int_0^{1+\sin \theta} r^3 \cos \theta dr d\theta \\
 &= k \int_0^{2\pi} \cos \theta \left[\frac{r^4}{4} \right]_0^{1+\sin \theta} d\theta = \frac{k}{4} \int_0^{2\pi} \cos \theta [(1 + \sin \theta)^4 - 0] d\theta = \frac{k}{4} \int_0^{2\pi} (1 + \sin \theta)^4 \cos \theta d\theta.
 \end{aligned}$$

To evaluate this integral, we make a substitution $u = 1 + \sin \theta$; then $du = \cos \theta d\theta$. We also change the limits of integration: if $\theta = 0$, then $u = 1 + \sin 0 = 1 + 0 = 1$; if $\theta = 2\pi$, then $u = 1 + \sin 2\pi = 1 + 0 = 1$. So

$$M_y = \frac{k}{4} \int_0^{2\pi} (1 + \sin \theta)^4 \cos \theta d\theta = \frac{k}{4} \int_1^1 u^4 du = 0,$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{0}{5\pi k/3} = 0.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y \rho(x, y) dA = \iint_R r \sin \theta \cdot kr \cdot r dr d\theta = k \int_0^{2\pi} \int_0^{1+\sin \theta} r^3 \sin \theta dr d\theta \\
 &= k \int_0^{2\pi} \sin \theta \left[\frac{r^4}{4} \right]_0^{1+\sin \theta} d\theta = k \int_0^{2\pi} \sin \theta \left[\frac{1}{4}(1 + \sin \theta)^4 - 0 \right] d\theta \\
 &= k \int_0^{2\pi} \left(\frac{1}{4} \sin \theta + \sin^2 \theta + \frac{3}{2} \sin^3 \theta + \sin^4 \theta + \frac{1}{4} \sin^5 \theta \right) d\theta \\
 &= k \int_0^{2\pi} \left[\frac{1}{4} \sin \theta + \frac{1}{2}(1 - \cos(2\theta)) + \frac{3}{2} \sin^3 \theta + \left[\frac{1}{2}(1 - \cos(2\theta)) \right]^2 + \frac{1}{4} \sin^5 \theta \right] d\theta \\
 &= k \int_0^{2\pi} \left(\frac{1}{4} \sin \theta + \frac{1}{2} - \frac{1}{2} \cos(2\theta) + \frac{3}{2} \sin^3 \theta + \frac{1}{4} - \frac{1}{2} \cos(2\theta) + \frac{1}{4} \cos^2(2\theta) + \frac{1}{4} \sin^5 \theta \right) d\theta \\
 &= k \int_0^{2\pi} \left(\frac{3}{4} + \frac{1}{4} \sin \theta - \cos(2\theta) + \frac{1}{4} \cdot \frac{1}{2}(1 + \cos(4\theta)) + \frac{3}{2} \sin^3 \theta + \frac{1}{4} \sin^5 \theta \right) d\theta \\
 &= k \int_0^{2\pi} \left(\frac{7}{8} + \frac{1}{4} \sin \theta - \cos(2\theta) + \frac{1}{8} \cos(4\theta) + \frac{3}{2} \sin^3 \theta + \frac{1}{4} \sin^5 \theta \right) d\theta \\
 &= k \left[\frac{7}{8} \int_0^{2\pi} d\theta + \frac{1}{4} \int_0^{2\pi} \sin \theta d\theta - \int_0^{2\pi} \cos(2\theta) d\theta + \frac{1}{8} \int_0^{2\pi} \cos(4\theta) d\theta + \frac{3}{2} \int_0^{2\pi} \sin^3 \theta d\theta + \frac{1}{4} \int_0^{2\pi} \sin^5 \theta d\theta \right].
 \end{aligned}$$

The first four integrals in parentheses can be evaluated directly:

$$\begin{aligned}
 \frac{7}{8} \int_0^{2\pi} d\theta &= \frac{7}{8} [\theta]_0^{2\pi} = \frac{7}{8}(2\pi - 0) = \frac{7\pi}{4}; \\
 \frac{1}{4} \int_0^{2\pi} \sin \theta d\theta &= \frac{1}{4} [-\cos \theta]_0^{2\pi} = \frac{1}{4}(-\cos 2\pi + \cos 0) = \frac{1}{4}(-1 + 1) = 0; \\
 \int_0^{2\pi} \cos(2\theta) d\theta &= \left[\frac{\sin(2\theta)}{2} \right]_0^{2\pi} = \frac{1}{2}[\sin(2\theta)]_0^{2\pi} = \frac{1}{2}(\sin(4\pi) - \sin 0) = \frac{1}{2}(0 - 0) = 0; \\
 \frac{1}{8} \int_0^{2\pi} \cos(4\theta) d\theta &= \frac{1}{8} \left[\frac{\sin(4\theta)}{4} \right]_0^{2\pi} = \frac{1}{32}[\sin(4\theta)]_0^{2\pi} = \frac{1}{32}(\sin(8\pi) - \sin 0) = \frac{1}{32}(0 - 0) = 0.
 \end{aligned}$$

To evaluate the last two integrals in parentheses, we use a trigonometric identity to transform their integrands: $\sin^3 \theta = \sin^2 \theta \cdot \sin \theta = (1 - \cos^2 \theta) \sin \theta$ and $\sin^5 \theta = \sin^4 \theta \cdot \sin \theta = (1 - \cos^2 \theta)^2 \sin \theta$. Then in both integrals we can make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = 0$, then $u = \cos 0 = 1$; if $\theta = 2\pi$, then $u = \cos 2\pi = 1$. So

$$\begin{aligned}
 \frac{3}{2} \int_0^{2\pi} \sin^3 \theta d\theta &= \frac{3}{2} \int_0^{2\pi} (1 - \cos^2 \theta) \sin \theta d\theta = \frac{3}{2} \int_1^1 (1 - u^2)(-du) = -\frac{3}{2} \int_1^1 (1 - u^2) du = 0; \\
 \frac{1}{4} \int_0^{2\pi} \sin^5 \theta d\theta &= \frac{1}{4} \int_0^{2\pi} (1 - \cos^2 \theta)^2 \sin \theta d\theta = \frac{1}{4} \int_1^1 (1 - u^2)^2(-du) = -\frac{1}{4} \int_1^1 (1 - u^2)^2 du = 0.
 \end{aligned}$$

Substituting these values back into the computation of M_x , we obtain

$$M_x = k \left(\frac{7\pi}{4} + 0 - 0 + 0 + 0 + 0 \right) = \frac{7\pi k}{4},$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{7\pi k/4}{5\pi k/3} = \frac{21}{20} = 1.05.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(0, \frac{21}{20} \right) = (0, 1.05)$.

18. The region R enclosed by $r = \cos \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$, is shown in the figure below. In polar coordinates, it is given by $0 \leq r \leq \cos \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. The mass density of the lamina is proportional to the distance from the pole; that is, $\rho(r, \theta) = kr$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R kr \cdot r dr d\theta = k \int_{-\pi/2}^{\pi/2} \int_0^{\cos \theta} r^2 dr d\theta = k \int_{-\pi/2}^{\pi/2} \left[\frac{r^3}{3} \right]_0^{\cos \theta} d\theta \\ &= \frac{k}{3} \int_{-\pi/2}^{\pi/2} (\cos^3 \theta - 0) d\theta = \frac{k}{3} \int_{-\pi/2}^{\pi/2} \cos^2 \theta \cos \theta d\theta = \frac{k}{3} \int_{-\pi/2}^{\pi/2} (1 - \sin^2 \theta) \cos \theta d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$. We also change the limits of integration: if $\theta = -\frac{\pi}{2}$, then $u = \sin\left(-\frac{\pi}{2}\right) = -1$; if $\theta = \frac{\pi}{2}$, then $u = \sin \frac{\pi}{2} = 1$. So

$$\begin{aligned} M &= \frac{k}{3} \int_{-\pi/2}^{\pi/2} (1 - \sin^2 \theta) \cos \theta d\theta = \frac{k}{3} \int_{-1}^1 (1 - u^2) du = \frac{k}{3} \left[u - \frac{u^3}{3} \right]_{-1}^1 \\ &= \frac{k}{3} \left[\left(1 - \frac{1}{3}\right) - \left(-1 + \frac{1}{3}\right) \right] = \frac{k}{3} \left[\frac{2}{3} - \left(-\frac{2}{3}\right) \right] = \frac{k}{3} \cdot \frac{4}{3} \\ &= \boxed{\frac{4k}{9}, \text{ where } k \text{ is the constant of proportionality}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x \rho(x, y) dA = \iint_R r \cos \theta \cdot kr \cdot r dr d\theta = k \int_{-\pi/2}^{\pi/2} \int_0^{\cos \theta} r^3 \cos \theta dr d\theta \\ &= k \int_{-\pi/2}^{\pi/2} \cos \theta \left[\frac{r^4}{4} \right]_0^{\cos \theta} d\theta = \frac{k}{4} \int_{-\pi/2}^{\pi/2} \cos \theta (\cos^4 \theta - 0) d\theta = \frac{k}{4} \int_{-\pi/2}^{\pi/2} \cos^5 \theta d\theta \\ &= \frac{k}{4} \int_{-\pi/2}^{\pi/2} (\cos^2 \theta)^2 \cos \theta d\theta = \frac{k}{4} \int_{-\pi/2}^{\pi/2} (1 - \sin^2 \theta)^2 \cos \theta d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$. We also change the

limits of integration: if $\theta = -\frac{\pi}{2}$, then $u = \sin\left(-\frac{\pi}{2}\right) = -1$; if $\theta = \frac{\pi}{2}$, then $u = \sin\frac{\pi}{2} = 1$. So

$$\begin{aligned} M_y &= \frac{k}{4} \int_{-\pi/2}^{\pi/2} (1 - \sin^2 \theta)^2 \cos \theta \, d\theta = \frac{k}{4} \int_{-1}^1 (1 - u^2)^2 \, du \\ &= \frac{k}{4} \int_{-1}^1 (1 - 2u^2 + u^4) \, du = \frac{k}{4} \left[u - \frac{2u^3}{3} + \frac{u^5}{5} \right]_{-1}^1 \\ &= \frac{k}{4} \left[\left(1 - \frac{2}{3} + \frac{1}{5}\right) - \left(-1 + \frac{2}{3} - \frac{1}{5}\right) \right] = \frac{k}{4} \left[\frac{8}{15} - \left(-\frac{8}{15}\right) \right] = \frac{k}{4} \cdot \frac{16}{15} = \frac{4k}{15}, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{4k/15}{4k/9} = \frac{3}{5} = 0.6.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) \, dA = \iint_R r \sin \theta \cdot k r \cdot r \, dr \, d\theta = k \int_{-\pi/2}^{\pi/2} \int_0^{\cos \theta} r^3 \sin \theta \, dr \, d\theta \\ &= k \int_{-\pi/2}^{\pi/2} \sin \theta \left[\frac{r^4}{4} \right]_0^{\cos \theta} d\theta = \frac{k}{4} \int_{-\pi/2}^{\pi/2} \sin \theta (\cos^4 \theta - 0) \, d\theta = \frac{k}{4} \int_{-\pi/2}^{\pi/2} \cos^4 \theta \sin \theta \, d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos \theta$; then $du = -\sin \theta \, d\theta$, so $\sin \theta \, d\theta = -du$. We also change the limits of integration: if $\theta = -\frac{\pi}{2}$, then $u = \cos\left(-\frac{\pi}{2}\right) = 0$; if $\theta = \frac{\pi}{2}$, then $u = \cos\frac{\pi}{2} = 0$. So

$$M_x = \frac{k}{4} \int_{-\pi/2}^{\pi/2} \cos^4 \theta \sin \theta \, d\theta = \frac{k}{4} \int_0^0 u^4 (-du) = -\frac{k}{4} \int_0^0 u^4 \, du = 0,$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{0}{4k/9} = 0.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{3}{5}, 0\right) = (0.6, 0)$.

19. The region R lying inside the graph of $r = 2a \sin \theta$ and outside the graph of $r = a$ is shown in the figure below. The graphs intersect at the points where

$$2a \sin \theta = a, \quad \text{so } 2 \sin \theta = 1, \quad \text{so } \sin \theta = \frac{1}{2}, \quad \text{so } \theta = \frac{\pi}{6}, \frac{5\pi}{6}.$$

So in polar coordinates, R is given by $a \leq r \leq 2a \sin \theta$, $\frac{\pi}{6} \leq \theta \leq \frac{5\pi}{6}$. The mass density of the lamina is inversely proportional to the distance from the pole; that is, $\rho(r, \theta) = \frac{k}{r}$, where k is a constant

coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R \frac{k}{r} \cdot r dr d\theta = k \int_{\pi/6}^{5\pi/6} \int_a^{2a \sin \theta} dr d\theta = k \int_{\pi/6}^{5\pi/6} [r]_a^{2a \sin \theta} d\theta \\
 &= k \int_{\pi/6}^{5\pi/6} (2a \sin \theta - a) d\theta = ka \int_{\pi/6}^{5\pi/6} (2 \sin \theta - 1) d\theta = ka [-2 \cos \theta - \theta]_{\pi/6}^{5\pi/6} \\
 &= ka \left[\left(-2 \cos \frac{5\pi}{6} - \frac{5\pi}{6} \right) - \left(-2 \cos \frac{\pi}{6} - \frac{\pi}{6} \right) \right] = ka \left[\sqrt{3} - \frac{5\pi}{6} + \sqrt{3} + \frac{\pi}{6} \right] = \\
 &= ka \left(2\sqrt{3} - \frac{2\pi}{3} \right) = \boxed{2ka \left(\sqrt{3} - \frac{\pi}{3} \right) \approx 1.370ka}.
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x \rho(x, y) dA = \iint_R r \cos \theta \cdot \frac{k}{r} \cdot r dr d\theta = k \int_{\pi/6}^{5\pi/6} \int_a^{2a \sin \theta} r \cos \theta dr d\theta \\
 &= k \int_{\pi/6}^{5\pi/6} \cos \theta \left[\frac{r^2}{2} \right]_a^{2a \sin \theta} d\theta = \frac{k}{2} \int_{\pi/6}^{5\pi/6} \cos \theta [(2a \sin \theta)^2 - a^2] d\theta \\
 &= \frac{ka^2}{2} \int_{\pi/6}^{5\pi/6} (4 \sin^2 \theta - 1) \cos \theta d\theta.
 \end{aligned}$$

To evaluate this integral, we make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$. We also change the limits of integration: if $\theta = \frac{\pi}{6}$, then $u = \sin \frac{\pi}{6} = \frac{1}{2}$; if $\theta = \frac{5\pi}{6}$, then $u = \sin \frac{5\pi}{6} = \frac{1}{2}$. So

$$M_y = \frac{ka^2}{2} \int_{\pi/6}^{5\pi/6} (4 \sin^2 \theta - 1) \cos \theta d\theta = \frac{ka^2}{2} \int_{1/2}^{1/2} (4u^2 - 1) du = 0,$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{0}{ka \left(2\sqrt{3} - \frac{2\pi}{3} \right)} = 0.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y \rho(x, y) dA = \iint_R r \sin \theta \cdot \frac{k}{r} \cdot r dr d\theta = k \int_{\pi/6}^{5\pi/6} \int_a^{2a \sin \theta} r \sin \theta dr d\theta \\
 &= k \int_{\pi/6}^{5\pi/6} \sin \theta \left[\frac{r^2}{2} \right]_a^{2a \sin \theta} d\theta = \frac{k}{2} \int_{\pi/6}^{5\pi/6} \sin \theta [(2a \sin \theta)^2 - a^2] d\theta \\
 &= \frac{ka^2}{2} \int_{\pi/6}^{5\pi/6} (4 \sin^2 \theta - 1) \sin \theta d\theta = \frac{ka^2}{2} \int_{\pi/6}^{5\pi/6} [4(1 - \cos^2 \theta) - 1] \sin \theta d\theta \\
 &= \frac{ka^2}{2} \int_{\pi/6}^{5\pi/6} (3 - 4 \cos^2 \theta) \sin \theta d\theta.
 \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = \frac{\pi}{6}$, then $u = \cos \frac{\pi}{6} = \frac{\sqrt{3}}{2}$; if $\theta = \frac{5\pi}{6}$, then $u = \cos \frac{5\pi}{6} =$

$-\frac{\sqrt{3}}{2}$. So

$$\begin{aligned}
 M_x &= \frac{ka^2}{2} \int_{\pi/6}^{5\pi/6} (3 - 4\cos^2 \theta) \sin \theta \, d\theta = \frac{ka^2}{2} \int_{\sqrt{3}/2}^{-\sqrt{3}/2} (3 - 4u^2) (-du) \\
 &= -\frac{ka^2}{2} \int_{\sqrt{3}/2}^{-\sqrt{3}/2} (3 - 4u^2) \, du = \frac{ka^2}{2} \int_{-\sqrt{3}/2}^{\sqrt{3}/2} (3 - 4u^2) \, du = \frac{ka^2}{2} \cdot 2 \int_0^{\sqrt{3}/2} (3 - 4u^2) \, du \\
 &= ka^2 \int_0^{\sqrt{3}/2} (3 - 4u^2) \, du = ka^2 \left[3u - \frac{4}{3}u^3 \right]_0^{\sqrt{3}/2} = ka^2 \left\{ \left[3 \cdot \frac{\sqrt{3}}{2} - \frac{4}{3} \cdot \left(\frac{\sqrt{3}}{2} \right)^3 \right] - (0 - 0) \right\} \\
 &= ka^2 \left(\frac{3\sqrt{3}}{2} - \frac{\sqrt{3}}{2} \right) = ka^2 \sqrt{3},
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{ka^2 \sqrt{3}}{ka(2\sqrt{3} - \frac{2\pi}{3})} = \frac{a\sqrt{3}}{2\sqrt{3} - \frac{2\pi}{3}} = \frac{3a\sqrt{3}}{6\sqrt{3} - 2\pi} = \frac{3\sqrt{3}a}{2(3\sqrt{3} - \pi)}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(0, \frac{3\sqrt{3}a}{2(3\sqrt{3} - \pi)} \right) \approx (0, 1.265a)$.

20. The region R lying outside the limaçon $r = 2 - \cos \theta$ and inside the circle $r = 4 \cos \theta$ is shown in the figure below. The graphs intersect at the points where

$$2 - \cos \theta = 4 \cos \theta, \quad \text{so} \quad 5 \cos \theta = 2, \quad \text{so} \quad \cos \theta = \frac{2}{5}, \quad \text{so} \quad \theta = \pm \cos^{-1} \left(\frac{2}{5} \right).$$

So in polar coordinates, R is given by $2 - \cos \theta \leq r \leq 4 \cos \theta$, $-\alpha \leq \theta \leq \alpha$, where we denoted $\alpha = \cos^{-1} \left(\frac{2}{5} \right)$ for brevity. The mass density of the lamina is inversely proportional to the distance

from the pole; that is, $\rho(r, \theta) = \frac{k}{r}$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) \, dA = \iint_R \frac{k}{r} \cdot r \, dr \, d\theta = k \int_{-\alpha}^{\alpha} \int_{2-\cos \theta}^{4 \cos \theta} dr \, d\theta = k \int_{-\alpha}^{\alpha} [r]_{2-\cos \theta}^{4 \cos \theta} d\theta \\
 &= k \int_{-\alpha}^{\alpha} [4 \cos \theta - (2 - \cos \theta)] \, d\theta = k \int_{-\alpha}^{\alpha} (5 \cos \theta - 2) \, d\theta = k [5 \sin \theta - 2\theta]_{-\alpha}^{\alpha} \\
 &= k [(5 \sin \alpha - 2\alpha) - (5 \sin(-\alpha) - 2(-\alpha))] = k [(5 \sin \alpha - 2\alpha) - (-5 \sin \alpha + 2\alpha)] \\
 &= k(10 \sin \alpha - 4\alpha) = k \left[10 \cdot \frac{\sqrt{21}}{5} - 4 \cos^{-1} \left(\frac{2}{5} \right) \right] = \boxed{k \left[2\sqrt{21} - 4 \cos^{-1} \left(\frac{2}{5} \right) \right] \approx 4.528k},
 \end{aligned}$$

where we used the value $\sin \alpha = \sqrt{1 - \cos^2 \alpha} = \sqrt{1 - \left(\frac{2}{5}\right)^2} = \sqrt{1 - \frac{4}{25}} = \sqrt{\frac{21}{25}} = \frac{\sqrt{21}}{5}$ (positive since $0 < \alpha < \frac{\pi}{2}$).

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x \rho(x, y) dA = \iint_R r \cos \theta \cdot \frac{k}{r} \cdot r dr d\theta = k \int_{-\alpha}^{\alpha} \int_{2-\cos \theta}^{4 \cos \theta} r \cos \theta dr d\theta \\
 &= k \int_{-\alpha}^{\alpha} \cos \theta \left[\frac{r^2}{2} \right]_{2-\cos \theta}^{4 \cos \theta} d\theta = k \int_{-\alpha}^{\alpha} \frac{1}{2} \cos \theta [(4 \cos \theta)^2 - (2 - \cos \theta)^2] d\theta \\
 &= k \int_{-\alpha}^{\alpha} \frac{1}{2} \cos \theta (16 \cos^2 \theta - 4 + 4 \cos \theta - \cos^2 \theta) d\theta = k \int_{-\alpha}^{\alpha} \left(\frac{15}{2} \cos^3 \theta + 2 \cos^2 \theta - 2 \cos \theta \right) d\theta \\
 &= k \int_{-\alpha}^{\alpha} \left[\frac{15}{2} \cos^2 \theta \cos \theta + 2 \cdot \frac{1}{2} (1 + \cos(2\theta)) - 2 \cos \theta \right] d\theta \\
 &= k \int_{-\alpha}^{\alpha} \left[\frac{15}{2} (1 - \sin^2 \theta) \cos \theta + 1 + \cos(2\theta) - 2 \cos \theta \right] d\theta \\
 &= k \int_{-\alpha}^{\alpha} \left(\frac{15}{2} \cos \theta - \frac{15}{2} \sin^2 \theta \cos \theta + 1 + \cos(2\theta) - 2 \cos \theta \right) d\theta \\
 &= k \int_{-\alpha}^{\alpha} \left(1 + \frac{11}{2} \cos \theta + \cos(2\theta) - \frac{15}{2} \sin^2 \theta \cos \theta \right) d\theta \\
 &= k \left(\int_{-\alpha}^{\alpha} d\theta + \frac{11}{2} \int_{-\alpha}^{\alpha} \cos \theta d\theta + \int_{-\alpha}^{\alpha} \cos(2\theta) d\theta - \frac{15}{2} \int_{-\alpha}^{\alpha} \sin^2 \theta \cos \theta d\theta \right).
 \end{aligned}$$

The first three integrals in parentheses can be evaluated directly:

$$\begin{aligned}
 \int_{-\alpha}^{\alpha} d\theta &= [\theta]_{-\alpha}^{\alpha} = \alpha - (-\alpha) = 2\alpha = 2 \cos^{-1} \left(\frac{2}{5} \right); \\
 \frac{11}{2} \int_{-\alpha}^{\alpha} \cos \theta d\theta &= \frac{11}{2} [\sin \theta]_{-\alpha}^{\alpha} = \frac{11}{2} [\sin \alpha - \sin(-\alpha)] = \frac{11}{2} \cdot 2 \sin \alpha = 11 \sin \alpha = 11 \cdot \frac{\sqrt{21}}{5} = \frac{11\sqrt{21}}{5}; \\
 \int_{-\alpha}^{\alpha} \cos(2\theta) d\theta &= \left[\frac{\sin(2\theta)}{2} \right]_{-\alpha}^{\alpha} = \frac{1}{2} [\sin(2\alpha) - \sin(-2\alpha)] = \frac{1}{2} \cdot 2 \sin(2\alpha) = \sin(2\alpha) = \frac{4\sqrt{21}}{25},
 \end{aligned}$$

where in the last computation we used the value $\sin(2\alpha) = 2 \sin \alpha \cos \alpha = 2 \cdot \frac{\sqrt{21}}{5} \cdot \frac{2}{5} = \frac{4\sqrt{21}}{25}$.

To evaluate the last integral in parentheses, we make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$.

We also change the limits of integration: if $\theta = -\alpha$, then $u = \sin(-\alpha) = -\frac{\sqrt{21}}{5}$; if $\theta = \alpha$, then

$u = \sin \alpha = \frac{\sqrt{21}}{5}$. So

$$\begin{aligned}
 \frac{15}{2} \int_{-\alpha}^{\alpha} \sin^2 \theta \cos \theta d\theta &= \frac{15}{2} \int_{-\sqrt{21}/5}^{\sqrt{21}/5} u^2 du = \frac{15}{2} \cdot 2 \int_0^{\sqrt{21}/5} u^2 du = 15 \int_0^{\sqrt{21}/5} u^2 du \\
 &= 15 \left[\frac{u^3}{3} \right]_0^{\sqrt{21}/5} = 5 \left[\left(\frac{\sqrt{21}}{5} \right)^3 - 0^3 \right] = 5 \cdot \frac{21\sqrt{21}}{125} = \frac{21\sqrt{21}}{25}.
 \end{aligned}$$

Substituting these values back into the computation of M_y , we obtain

$$M_y = k \left[2 \cos^{-1} \left(\frac{2}{5} \right) + \frac{11\sqrt{21}}{5} + \frac{4\sqrt{21}}{25} - \frac{21\sqrt{21}}{25} \right] = k \left[2 \cos^{-1} \left(\frac{2}{5} \right) + \frac{38\sqrt{21}}{25} \right],$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{k \left[2 \cos^{-1} \left(\frac{2}{5} \right) + \frac{38\sqrt{21}}{25} \right]}{k \left[2\sqrt{21} - 4 \cos^{-1} \left(\frac{2}{5} \right) \right]} = \frac{2 \cos^{-1} \left(\frac{2}{5} \right) + \frac{38\sqrt{21}}{25}}{2\sqrt{21} - 4 \cos^{-1} \left(\frac{2}{5} \right)} = \frac{25 \cos^{-1} \left(\frac{2}{5} \right) + 19\sqrt{21}}{25\sqrt{21} - 50 \cos^{-1} \left(\frac{2}{5} \right)} \approx 2.050.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) dA = \iint_R r \sin \theta \cdot \frac{k}{r} \cdot r dr d\theta = k \int_{-\alpha}^{\alpha} \int_{2-\cos \theta}^{4 \cos \theta} r \sin \theta dr d\theta \\ &= k \int_{-\alpha}^{\alpha} \sin \theta \left[\frac{r^2}{2} \right]_{2-\cos \theta}^{4 \cos \theta} d\theta = k \int_{-\alpha}^{\alpha} \frac{1}{2} \sin \theta [(4 \cos \theta)^2 - (2 - \cos \theta)^2] d\theta \\ &= k \int_{-\alpha}^{\alpha} \frac{1}{2} \sin \theta (16 \cos^2 \theta - 4 + 4 \cos \theta - \cos^2 \theta) d\theta = k \int_{-\alpha}^{\alpha} \left(\frac{15}{2} \cos^2 \theta + 2 \cos \theta - 2 \right) \sin \theta d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = -\alpha$, then $u = \cos(-\alpha) = \frac{2}{5}$; if $\theta = \alpha$, then $u = \cos \alpha = \frac{2}{5}$. So

$$\begin{aligned} M_x &= k \int_{-\alpha}^{\alpha} \left(\frac{15}{2} \cos^2 \theta + 2 \cos \theta - 2 \right) \sin \theta d\theta \\ &= k \int_{2/5}^{2/5} \left(\frac{15}{2} u^2 + 2u - 2 \right) (-du) = -k \int_{2/5}^{2/5} \left(\frac{15}{2} u^2 + 2u - 2 \right) du = 0, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{0}{k [2\sqrt{21} - 4 \cos^{-1} (\frac{2}{5})]} = 0.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{25 \cos^{-1} (\frac{2}{5}) + 19\sqrt{21}}{25\sqrt{21} - 50 \cos^{-1} (\frac{2}{5})}, 0 \right) \approx (2.050, 0)$.

21. The region R enclosed by the lines $2x + 3y = 6$, $x = 0$ (the y -axis), and $y = 0$ (the x -axis) is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 2 - \frac{2x}{3}$, $0 \leq x \leq 3$. Assuming that the lamina is homogeneous of constant mass density ρ , its moment of inertia about the x -axis can be found as a double integral:

$$\begin{aligned} I_x &= \iint_R y^2 \rho(x, y) dA = \iint_R y^2 \rho dA = \rho \int_0^3 \int_0^{2-2x/3} y^2 dy dx = \rho \int_0^3 \left[\frac{y^3}{3} \right]_0^{2-2x/3} dx \\ &= \rho \int_0^3 \left[\frac{(2 - \frac{2x}{3})^3}{3} - 0 \right] dx = \rho \int_0^3 \left(\frac{8}{3} - \frac{8x}{3} + \frac{8x^2}{9} - \frac{8x^3}{81} \right) dx \\ &= \rho \left[\frac{8x}{3} - \frac{4x^2}{3} + \frac{8x^3}{27} - \frac{2x^4}{81} \right]_0^3 = \rho [(8 - 12 + 8 - 2) - 0] = \boxed{2\rho}. \end{aligned}$$

22. For the lamina from Problem 21 (see the figure above), its moment of inertia about the y -axis can be found as a double integral:

$$\begin{aligned}
 I_y &= \iint_R x^2 \rho(x, y) dA = \iint_R x^2 \rho dA = \rho \int_0^3 \int_0^{2-2x/3} x^2 dy dx = \rho \int_0^3 x^2 [y]_0^{2-2x/3} dx \\
 &= \rho \int_0^3 x^2 \left[\left(2 - \frac{2x}{3} \right) - 0 \right] dx = \rho \int_0^3 \left(2x^2 - \frac{2x^3}{3} \right) dx = \rho \left[\frac{2x^3}{3} - \frac{x^4}{6} \right]_0^3 \\
 &= \rho \left[\left(18 - \frac{27}{2} \right) - 0 \right] = \boxed{\frac{9\rho}{2}}.
 \end{aligned}$$

23. The rectangular region R enclosed in the first quadrant by the lines $x = a$ ($a > 0$) and $y = b$ ($b > 0$) is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = b$, $0 \leq x \leq a$. Assuming that the lamina is homogeneous of constant mass density ρ , its moment of inertia about the y -axis can be found as a double integral:

$$\begin{aligned}
 I_y &= \iint_R x^2 \rho(x, y) dA = \iint_R x^2 \rho dA = \rho \int_0^a \int_0^b x^2 dy dx = \rho \int_0^a x^2 [y]_0^b dx \\
 &= \rho \int_0^a x^2 (b - 0) dx = b\rho \int_0^a x^2 dx = b\rho \left[\frac{x^3}{3} \right]_0^a = b\rho \left(\frac{a^3}{3} - 0 \right) = \boxed{\frac{a^3 b \rho}{3}}.
 \end{aligned}$$

24. For the lamina from Problem 23 (see the figure above), its moment of inertia about the x -axis can be found as a double integral:

$$\begin{aligned}
 I_x &= \iint_R y^2 \rho(x, y) dA = \iint_R y^2 \rho dA = \rho \int_0^a \int_0^b y^2 dy dx = \rho \int_0^a \left[\frac{y^3}{3} \right]_0^b dx \\
 &= \rho \int_0^a \frac{b^3}{3} dx = \frac{b^3 \rho}{3} \int_0^a dx = \frac{b^3 \rho}{3} [x]_0^a = \frac{b^3 \rho}{3} (a - 0) = \boxed{\frac{ab^3 \rho}{3}}.
 \end{aligned}$$

25. The region R enclosed by the parabolas $y = x^2$ and $y = 2 - x^2$ is shown in the figure below. The graphs intersect at the points where

$$x^2 = 2 - x^2, \quad \text{so} \quad 2x^2 = 2, \quad \text{so} \quad x^2 = 1, \quad \text{so} \quad x = \pm 1.$$

Notice that R is an x -simple region: it is bounded between $y = x^2$ and $y = 2 - x^2$, $-1 \leq x \leq 1$. Assuming that the lamina is homogeneous of constant mass density ρ , its moment of inertia about the y -axis can be found as a double integral:

$$\begin{aligned} I_y &= \iint_R x^2 \rho(x, y) dA = \iint_R x^2 \rho dA = \rho \int_{-1}^1 \int_{x^2}^{2-x^2} x^2 dy dx = \rho \int_{-1}^1 x^2 [y]_{x^2}^{2-x^2} dx \\ &= \rho \int_{-1}^1 x^2 [(2 - x^2) - x^2] dx = \rho \int_{-1}^1 (2x^2 - 2x^4) dx = \rho \left[\frac{2x^3}{3} - \frac{2x^5}{5} \right]_{-1}^1 \\ &= \rho \left[\left(\frac{2}{3} - \frac{2}{5} \right) - \left(-\frac{2}{3} + \frac{2}{5} \right) \right] = \rho \left[\frac{4}{15} - \left(-\frac{4}{15} \right) \right] = \boxed{\frac{8\rho}{15}}. \end{aligned}$$

26. The graph of $y^2 = x^2(4 - x)$ and the region R it encloses in its loop are shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = -x\sqrt{4-x}$ and $y = x\sqrt{4-x}$, $0 \leq x \leq 4$. Assuming that the lamina is homogeneous of constant mass density ρ , its moment of inertia about the y -axis can be found as a double integral:

$$\begin{aligned} I_y &= \iint_R x^2 \rho(x, y) dA = \iint_R x^2 \rho dA = \rho \int_0^4 \int_{-x\sqrt{4-x}}^{x\sqrt{4-x}} x^2 dy dx = \rho \int_0^4 x^2 [y]_{-x\sqrt{4-x}}^{x\sqrt{4-x}} dx \\ &= \rho \int_0^4 x^2 [x\sqrt{4-x} - (-x\sqrt{4-x})] dx = \rho \int_0^4 x^2 \cdot 2x\sqrt{4-x} dx = 2\rho \int_0^4 x^3 \sqrt{4-x} dx. \end{aligned}$$

To evaluate this integral, we make a substitution $u = 4 - x$; then $du = -dx$, so $dx = -du$. We also change the limits of integration: if $x = 0$, then $u = 4 - 0 = 4$; if $x = 4$, then $u = 4 - 4 = 0$. So

$$\begin{aligned} I_y &= 2\rho \int_0^4 x^3 \sqrt{4-x} dx = 2\rho \int_4^0 (4-u)^3 \sqrt{u} (-du) = -2\rho \int_4^0 (64 - 48u + 12u^2 - u^3) u^{1/2} du \\ &= 2\rho \int_0^4 (64u^{1/2} - 48u^{3/2} + 12u^{5/2} - u^{7/2}) du = 2\rho \left[64 \cdot \frac{u^{3/2}}{3/2} - 48 \cdot \frac{u^{5/2}}{5/2} + 12 \cdot \frac{u^{7/2}}{7/2} - \frac{u^{9/2}}{9/2} \right]_0^4 \\ &= 2\rho \left[\frac{128}{3} (\sqrt{u})^3 - \frac{96}{5} (\sqrt{u})^5 + \frac{24}{7} (\sqrt{u})^7 - \frac{2}{9} (\sqrt{u})^9 \right]_0^4 \\ &= 2\rho \left\{ \left[\frac{128}{3} (\sqrt{4})^3 - \frac{96}{5} (\sqrt{4})^5 + \frac{24}{7} (\sqrt{4})^7 - \frac{2}{9} (\sqrt{4})^9 \right] - (0 - 0 + 0 - 0) \right\} \\ &= 2\rho \left(\frac{128}{3} \cdot 8 - \frac{96}{5} \cdot 32 + \frac{24}{7} \cdot 128 - \frac{2}{9} \cdot 512 \right) = 2\rho \cdot \frac{16384}{315} = \boxed{\frac{32768\rho}{315}}. \end{aligned}$$

Applications and Extensions

27. If we place this lamina, which has the shape of a flat circular washer with inner radius a and outer radius $2a$, in the polar coordinate system so that its center is at the pole, then it occupies the region R given by $a \leq r \leq 2a$, $0 \leq \theta \leq 2\pi$; see the figure below. The mass density of the lamina is inversely proportional to the square of the distance from the center; that is, $\rho(r, \theta) = \frac{k}{r^2}$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) \, dA = \iint_R \frac{k}{r^2} \cdot r \, dr \, d\theta = k \int_0^{2\pi} \int_a^{2a} \frac{1}{r} \, dr \, d\theta \\
 &= k \int_0^{2\pi} [\ln |r|]_a^{2a} \, d\theta = k \int_0^{2\pi} (\ln 2a - \ln a) \, d\theta = k \int_0^{2\pi} \ln \left(\frac{2a}{a} \right) \, d\theta \\
 &= k \ln 2 \int_0^{2\pi} d\theta = k \ln 2 \cdot [\theta]_0^{2\pi} = k \ln 2 \cdot (2\pi - 0) = \boxed{2\pi k \ln 2}.
 \end{aligned}$$

28. For the lamina from Problem 27 (see the figure above), if the mass density is inversely proportional to the distance from the center, then it is $\rho(r, \theta) = \frac{k}{r}$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) \, dA = \iint_R \frac{k}{r} \cdot r \, dr \, d\theta = k \int_0^{2\pi} \int_a^{2a} dr \, d\theta = k \int_0^{2\pi} [r]_a^{2a} \, d\theta \\
 &= k \int_0^{2\pi} (2a - a) \, d\theta = ka \int_0^{2\pi} d\theta = ka [\theta]_0^{2\pi} = ka \cdot (2\pi - 0) = \boxed{2\pi ka}.
 \end{aligned}$$

29. The region R enclosed on the left by the line $x = a$ ($a > 0$) and on the right by the circle $r = 2a \cos \theta$ is shown in the figure below. The equation of the line can be converted to polar coordinates as

$$x = a, \quad \text{so} \quad r \cos \theta = a, \quad \text{so} \quad r = \frac{a}{\cos \theta}, \quad \text{or} \quad r = a \sec \theta.$$

To find the coordinates of their points of intersection, we set the equations of the line and the circle equal to each other:

$$a = 2a \cos \theta, \quad \text{so} \quad \cos \theta = \frac{1}{2}, \quad \text{so} \quad \theta = \pm \frac{\pi}{4}.$$

So in polar coordinates R is given by $a \sec \theta \leq r \leq 2a \cos \theta$, $-\frac{\pi}{4} \leq \theta \leq \frac{\pi}{4}$. The mass density of the lamina is inversely proportional to the distance from the y -axis; that is, $\rho(r, \theta) = \frac{k}{x} = \frac{k}{r \cos \theta} = \frac{k \sec \theta}{r}$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R \frac{k \sec \theta}{r} \cdot r dr d\theta = k \int_{-\pi/4}^{\pi/4} \int_{a \sec \theta}^{2a \cos \theta} \sec \theta dr d\theta = k \int_{-\pi/4}^{\pi/4} \sec \theta [r]_{a \sec \theta}^{2a \cos \theta} d\theta \\ &= k \int_{-\pi/4}^{\pi/4} \sec \theta (2a \cos \theta - a \sec \theta) d\theta = ka \int_{-\pi/4}^{\pi/4} (2 - \sec^2 \theta) d\theta = ka [2\theta - \tan \theta]_{-\pi/4}^{\pi/4} \\ &= ka \left\{ \left[2 \cdot \frac{\pi}{4} - \tan \frac{\pi}{4} \right] - \left[2 \cdot \left(-\frac{\pi}{4} \right) - \tan \left(-\frac{\pi}{4} \right) \right] \right\} \\ &= ka \left[\left(\frac{\pi}{2} - 1 \right) - \left(-\frac{\pi}{2} + 1 \right) \right] = \boxed{ka(\pi - 2) \approx 1.142ka}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x \rho(x, y) dA = \iint_R r \cos \theta \cdot \frac{k \sec \theta}{r} \cdot r dr d\theta = k \int_{-\pi/4}^{\pi/4} \int_{a \sec \theta}^{2a \cos \theta} r dr d\theta \\ &= k \int_{-\pi/4}^{\pi/4} \left[\frac{r^2}{2} \right]_{a \sec \theta}^{2a \cos \theta} d\theta = k \int_{-\pi/4}^{\pi/4} \left(2a^2 \cos^2 \theta - \frac{1}{2} a^2 \sec^2 \theta \right) d\theta \\ &= ka^2 \int_{-\pi/4}^{\pi/4} \left[2 \cdot \frac{1}{2} (1 + \cos(2\theta)) - \frac{1}{2} \sec^2 \theta \right] d\theta = ka^2 \int_{-\pi/4}^{\pi/4} \left(1 + \cos(2\theta) - \frac{1}{2} \sec^2 \theta \right) d\theta \\ &= ka^2 \left[\theta + \frac{1}{2} \sin(2\theta) - \frac{1}{2} \tan \theta \right]_{-\pi/4}^{\pi/4} \\ &= ka^2 \left\{ \left[\frac{\pi}{4} + \frac{1}{2} \sin \frac{\pi}{2} - \frac{1}{2} \tan \frac{\pi}{4} \right] - \left[-\frac{\pi}{4} + \frac{1}{2} \sin \left(-\frac{\pi}{2} \right) - \frac{1}{2} \tan \left(-\frac{\pi}{4} \right) \right] \right\} \\ &= ka^2 \left[\left(\frac{\pi}{4} + \frac{1}{2} - \frac{1}{2} \right) - \left(-\frac{\pi}{4} - \frac{1}{2} + \frac{1}{2} \right) \right] = \frac{ka^2 \pi}{2}, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{ka^2 \pi / 2}{ka(\pi - 2)} = \frac{a\pi}{2(\pi - 2)} \approx 1.376a.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) dA = \iint_R r \sin \theta \cdot \frac{k \sec \theta}{r} \cdot r dr d\theta = k \int_{-\pi/4}^{\pi/4} \int_{a \sec \theta}^{2a \cos \theta} r \tan \theta dr d\theta \\ &= k \int_{-\pi/4}^{\pi/4} \tan \theta \left[\frac{r^2}{2} \right]_{a \sec \theta}^{2a \cos \theta} d\theta = k \int_{-\pi/4}^{\pi/4} \tan \theta \left(2a^2 \cos^2 \theta - \frac{1}{2} a^2 \sec^2 \theta \right) d\theta \\ &= ka^2 \int_{-\pi/4}^{\pi/4} \left(2 \sin \theta \cos \theta - \frac{\sin \theta}{2 \cos^3 \theta} \right) d\theta = ka^2 \int_{-\pi/4}^{\pi/4} \left(2 \cos \theta - \frac{1}{2 \cos^3 \theta} \right) \sin \theta d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = -\frac{\pi}{4}$, then $u = \cos\left(-\frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}$; if $\theta = \frac{\pi}{4}$, then $u = \cos \frac{\pi}{4} = \frac{\sqrt{2}}{2}$. So

$$\begin{aligned} M_x &= ka^2 \int_{-\pi/4}^{\pi/4} \left(2 \cos \theta - \frac{1}{2 \cos^3 \theta}\right) \sin \theta d\theta \\ &= ka^2 \int_{\sqrt{2}/2}^{\sqrt{2}/2} \left(2u - \frac{1}{2u^3}\right) (-du) = -ka^2 \int_{\sqrt{2}/2}^{\sqrt{2}/2} \left(2u - \frac{1}{2u^3}\right) du = 0, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{0}{ka(\pi - 2)} = 0.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{a\pi}{2(\pi - 2)}, 0\right) \approx (1.376a, 0)$.

30. The smaller region R cut from the circle $r = 6$ by the line $r \cos \theta = 3$, which is equivalent to $r = 3 \sec \theta$, is shown in the figure below. The graphs intersect at the points where

$$3 \sec \theta = 6, \quad \text{so} \quad \sec \theta = 2, \quad \text{so} \quad \cos \theta = \frac{1}{2}, \quad \text{so} \quad \theta = \pm \frac{\pi}{3}.$$

So in polar coordinates R is given by $3 \sec \theta \leq r \leq 6$, $-\frac{\pi}{3} \leq \theta \leq \frac{\pi}{3}$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R \cos^2 \theta \cdot r dr d\theta = \int_{-\pi/3}^{\pi/3} \int_{3 \sec \theta}^6 \cos^2 \theta \cdot r dr d\theta \\ &= \int_{-\pi/3}^{\pi/3} \cos^2 \theta \left[\frac{r^2}{2} \right]_{3 \sec \theta}^6 d\theta = \int_{-\pi/3}^{\pi/3} \cos^2 \theta \left(18 - \frac{9}{2} \sec^2 \theta \right) d\theta = 9 \int_{-\pi/3}^{\pi/3} \left(2 \cos^2 \theta - \frac{1}{2} \right) d\theta \\ &= 9 \int_{-\pi/3}^{\pi/3} \left[2 \cdot \frac{1}{2} (1 + \cos(2\theta)) - \frac{1}{2} \right] d\theta = 9 \int_{-\pi/3}^{\pi/3} \left(1 + \cos(2\theta) - \frac{1}{2} \right) d\theta \\ &= 9 \int_{-\pi/3}^{\pi/3} \left(\frac{1}{2} + \cos(2\theta) \right) d\theta = 9 \left[\frac{1}{2} \theta + \frac{1}{2} \sin(2\theta) \right]_{-\pi/3}^{\pi/3} = \frac{9}{2} [\theta + \sin(2\theta)]_{-\pi/3}^{\pi/3} \\ &= \frac{9}{2} \left\{ \left[\frac{\pi}{3} + \sin \frac{2\pi}{3} \right] - \left[-\frac{\pi}{3} + \sin \left(-\frac{2\pi}{3} \right) \right] \right\} = \frac{9}{2} \left[\left(\frac{\pi}{3} + \frac{\sqrt{3}}{2} \right) - \left(-\frac{\pi}{3} - \frac{\sqrt{3}}{2} \right) \right] \\ &= \frac{9}{2} \left(\frac{2\pi}{3} + \sqrt{3} \right) = \boxed{3\pi + \frac{9\sqrt{3}}{2}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R r \cos \theta \cdot \cos^2 \theta \cdot r dr d\theta = \int_{-\pi/3}^{\pi/3} \int_{3 \sec \theta}^6 \cos^3 \theta \cdot r^2 dr d\theta \\ &= \int_{-\pi/3}^{\pi/3} \cos^3 \theta \left[\frac{r^3}{3} \right]_{3 \sec \theta}^6 d\theta = \int_{-\pi/3}^{\pi/3} \cos^3 \theta \cdot (72 - 9 \sec^3 \theta) d\theta \\ &= \int_{-\pi/3}^{\pi/3} (72 \cos^3 \theta - 9) d\theta = 72 \int_{-\pi/3}^{\pi/3} \cos^3 \theta d\theta - 9 \int_{-\pi/3}^{\pi/3} d\theta. \end{aligned}$$

The second integral can be evaluated directly:

$$9 \int_{-\pi/3}^{\pi/3} d\theta = 9 [\theta]_{-\pi/3}^{\pi/3} = 9 \left[\frac{\pi}{3} - \left(-\frac{\pi}{3} \right) \right] = 9 \cdot \frac{2\pi}{3} = 6\pi.$$

To evaluate the first integral, we use a trigonometric identity to transform the integrand: $\cos^3 \theta = \cos^2 \theta \cdot \cos \theta = (1 - \sin^2 \theta) \cos \theta$, and then make a substitution $u = \sin \theta$; then $du = \cos \theta d\theta$. We also change the limits of integration: if $\theta = -\frac{\pi}{3}$, then $u = \sin\left(-\frac{\pi}{3}\right) = -\frac{\sqrt{3}}{2}$; if $\theta = \frac{\pi}{3}$, then $u = \sin\frac{\pi}{3} = \frac{\sqrt{3}}{2}$. So

$$\begin{aligned} 72 \int_{-\pi/3}^{\pi/3} \cos^3 \theta d\theta &= 72 \int_{-\pi/3}^{\pi/3} (1 - \sin^2 \theta) \cos \theta d\theta = 72 \int_{-\sqrt{3}/2}^{\sqrt{3}/2} (1 - u^2) du = 72 \left[u - \frac{u^3}{3} \right]_{-\sqrt{3}/2}^{\sqrt{3}/2} \\ &= 72 \left[\left(\frac{\sqrt{3}}{2} - \frac{(\sqrt{3}/2)^3}{3} \right) - \left(-\frac{\sqrt{3}}{2} - \frac{(-\sqrt{3}/2)^3}{3} \right) \right] \\ &= 72 \left[\left(\frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{8} \right) - \left(-\frac{\sqrt{3}}{2} + \frac{\sqrt{3}}{8} \right) \right] = 72 \cdot \frac{3\sqrt{3}}{4} = 54\sqrt{3}. \end{aligned}$$

Substituting these values back into the computation of M_y , we obtain

$$M_y = 72 \int_{-\pi/3}^{\pi/3} \cos^3 \theta d\theta - 9 \int_{-\pi/3}^{\pi/3} d\theta = 54\sqrt{3} - 6\pi,$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{54\sqrt{3} - 6\pi}{3\pi + \frac{9\sqrt{3}}{2}} = \frac{36\sqrt{3} - 4\pi}{2\pi + 3\sqrt{3}} \approx 4.337.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R r \sin \theta \cdot \cos^2 \theta \cdot r dr d\theta = \int_{-\pi/3}^{\pi/3} \int_{3 \sec \theta}^6 \sin \theta \cos^2 \theta \cdot r^2 dr d\theta \\ &= \int_{-\pi/3}^{\pi/3} \sin \theta \cos^2 \theta \left[\frac{r^3}{3} \right]_{3 \sec \theta}^6 d\theta = \int_{-\pi/3}^{\pi/3} \sin \theta \cos^2 \theta \cdot (72 - 9 \sec^3 \theta) d\theta \\ &= \int_{-\pi/3}^{\pi/3} (72 \cos^2 \theta - 9 \sec \theta) \sin \theta d\theta = 9 \int_{-\pi/3}^{\pi/3} \left(8 \cos^2 \theta - \frac{1}{\cos \theta} \right) \sin \theta d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos \theta$; then $du = -\sin \theta d\theta$, so $\sin \theta d\theta = -du$. We also change the limits of integration: if $\theta = -\frac{\pi}{3}$, then $u = \cos\left(-\frac{\pi}{3}\right) = \frac{1}{2}$; if $\theta = \frac{\pi}{3}$, then $u = \cos\frac{\pi}{3} = \frac{1}{2}$. So

$$M_x = 9 \int_{-\pi/3}^{\pi/3} \left(8 \cos^2 \theta - \frac{1}{\cos \theta} \right) \sin \theta d\theta = 9 \int_{1/2}^{1/2} \left(8u^2 - \frac{1}{u} \right) (-du) = -9 \int_{1/2}^{1/2} \left(8u^2 - \frac{1}{u} \right) du = 0,$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{0}{3\pi + \frac{9\sqrt{3}}{2}} = 0.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{36\sqrt{3} - 4\pi}{2\pi + 3\sqrt{3}}, 0 \right) \approx (4.337, 0)$.

31. The region R enclosed by $y = x^2$ and $y = x^3$ is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = x^3$ and $y = x^2$, $0 \leq x \leq 1$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R \sqrt{xy} dA = \int_0^1 \int_{x^3}^{x^2} x^{1/2} y^{1/2} dy dx = \int_0^1 x^{1/2} \left[\frac{y^{3/2}}{3/2} \right]_{x^3}^{x^2} dx \\ &= \int_0^1 \frac{2}{3} x^{1/2} \left[(x^2)^{3/2} - (x^3)^{3/2} \right] dx = \frac{2}{3} \int_0^1 x^{1/2} (x^3 - x^{9/2}) dx = \frac{2}{3} \int_0^1 (x^{7/2} - x^5) dx \\ &= \frac{2}{3} \left[\frac{x^{9/2}}{9/2} - \frac{x^6}{6} \right]_0^1 = \frac{2}{3} \left[\frac{2}{9} x^{9/2} - \frac{1}{6} x^6 \right]_0^1 = \frac{2}{3} \left[\left(\frac{2}{9} - \frac{1}{6} \right) - (0 - 0) \right] = \frac{2}{3} \cdot \frac{1}{18} = \boxed{\frac{1}{27}}. \end{aligned}$$

32. The region R lying inside the circle $r = 4 \cos \theta$ and outside the circle $r = 2\sqrt{3}$ is shown in the figure below. The graphs intersect at the points where

$$4 \cos \theta = 2\sqrt{3}, \quad \text{so} \quad \cos \theta = \frac{\sqrt{3}}{2}, \quad \text{so} \quad \theta = \pm \frac{\pi}{6}.$$

So in polar coordinates, R is given by $2\sqrt{3} \leq r \leq 4 \cos \theta$, $-\frac{\pi}{6} \leq \theta \leq \frac{\pi}{6}$. The mass density of the lamina is inversely proportional to the distance from the origin; that is, $\rho(r, \theta) = \frac{k}{r}$, where k is a constant

coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R \frac{k}{r} \cdot r dr d\theta = k \int_{-\pi/6}^{\pi/6} \int_{2\sqrt{3}}^{4\cos\theta} dr d\theta = k \int_{-\pi/6}^{\pi/6} [r]_{2\sqrt{3}}^{4\cos\theta} d\theta \\
 &= k \int_{-\pi/6}^{\pi/6} (4\cos\theta - 2\sqrt{3}) d\theta = 2k \int_{-\pi/6}^{\pi/6} (2\cos\theta - \sqrt{3}) d\theta = 2k \left[2\sin\theta - \sqrt{3}\theta \right]_{-\pi/6}^{\pi/6} \\
 &= 2k \left\{ \left[2\sin\frac{\pi}{6} - \sqrt{3} \cdot \frac{\pi}{6} \right] - \left[2\sin\left(-\frac{\pi}{6}\right) - \sqrt{3} \cdot \left(-\frac{\pi}{6}\right) \right] \right\} \\
 &= 2k \left[\left(1 - \frac{\pi\sqrt{3}}{6} \right) - \left(-1 + \frac{\pi\sqrt{3}}{6} \right) \right] = 2k \left(2 - \frac{\pi\sqrt{3}}{3} \right) = \frac{2k}{3} (6 - \pi\sqrt{3}).
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R r\cos\theta \cdot \frac{k}{r} \cdot r dr d\theta = k \int_{-\pi/6}^{\pi/6} \int_{2\sqrt{3}}^{4\cos\theta} r\cos\theta dr d\theta \\
 &= k \int_{-\pi/6}^{\pi/6} \cos\theta \left[\frac{r^2}{2} \right]_{2\sqrt{3}}^{4\cos\theta} d\theta = k \int_{-\pi/6}^{\pi/6} \cos\theta (8\cos^2\theta - 6) d\theta \\
 &= 2k \int_{-\pi/6}^{\pi/6} [4(1 - \sin^2\theta) - 3] \cos\theta d\theta = 2k \int_{-\pi/6}^{\pi/6} (1 - 4\sin^2\theta) \cos\theta d\theta.
 \end{aligned}$$

To evaluate this integral, we make a substitution $u = \sin\theta$; then $du = \cos\theta d\theta$. We also change the limits of integration: if $\theta = -\frac{\pi}{6}$, then $u = \sin\left(-\frac{\pi}{6}\right) = -\frac{1}{2}$; if $\theta = \frac{\pi}{6}$, then $u = \sin\frac{\pi}{6} = \frac{1}{2}$. So

$$\begin{aligned}
 M_y &= 2k \int_{-\pi/6}^{\pi/6} (1 - 4\sin^2\theta) \cos\theta d\theta = 2k \int_{-1/2}^{1/2} (1 - 4u^2) du \\
 &= 2k \left[u - \frac{4u^3}{3} \right]_{-1/2}^{1/2} = 2k \left[\left(\frac{1}{2} - \frac{1}{6} \right) - \left(-\frac{1}{2} + \frac{1}{6} \right) \right] = 2k \cdot \frac{2}{3} = \frac{4k}{3},
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{4k/3}{(2k/3)(6 - \pi\sqrt{3})} = \frac{2}{6 - \pi\sqrt{3}} \approx 3.580.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x, y) dA = \iint_R r\sin\theta \cdot \frac{k}{r} \cdot r dr d\theta = k \int_{-\pi/6}^{\pi/6} \int_{2\sqrt{3}}^{4\cos\theta} r\sin\theta dr d\theta \\
 &= k \int_{-\pi/6}^{\pi/6} \sin\theta \left[\frac{r^2}{2} \right]_{2\sqrt{3}}^{4\cos\theta} d\theta = k \int_{-\pi/6}^{\pi/6} \sin\theta (8\cos^2\theta - 6) d\theta = 2k \int_{-\pi/6}^{\pi/6} (4\cos^2\theta - 3) \sin\theta d\theta.
 \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos\theta$; then $du = -\sin\theta d\theta$, so $\sin\theta d\theta = -du$.

We also change the limits of integration: if $\theta = -\frac{\pi}{6}$, then $u = \cos\left(-\frac{\pi}{6}\right) = \frac{\sqrt{3}}{2}$; if $\theta = \frac{\pi}{6}$, then

$$u = \cos\frac{\pi}{6} = \frac{\sqrt{3}}{2}. \text{ So}$$

$$M_x = 2k \int_{-\pi/6}^{\pi/6} (4\cos^2\theta - 3) \sin\theta d\theta = 2k \int_{\sqrt{3}/2}^{\sqrt{3}/2} (4u^2 - 3) (-du) = -2k \int_{\sqrt{3}/2}^{\sqrt{3}/2} (4u^2 - 3) du = 0,$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{0}{(2k/3)(6 - \pi\sqrt{3})} = 0.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{2}{6 - \pi\sqrt{3}}, 0 \right) \approx (3.580, 0)$.

33. The region R enclosed by the line $x = y - 2$ and the parabola $x = -y^2$ is shown in the figure below. The graphs intersect at the points where

$$y - 2 = -y^2, \quad \text{so} \quad y^2 + y - 2 = 0, \quad \text{so} \quad (y + 2)(y - 1) = 0, \quad \text{so} \quad y = -2, 1.$$

Notice that R is a y -simple region: it is bounded between $x = y - 2$ and $x = -y^2$, $-2 \leq y \leq 1$. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R x^2 dA = \int_{-2}^1 \int_{y-2}^{-y^2} x^2 dx dy = \int_{-2}^1 \left[\frac{x^3}{3} \right]_{y-2}^{-y^2} dy \\ &= \int_{-2}^1 \frac{1}{3} [(-y^2)^3 - (y-2)^3] dy = \int_{-2}^1 \frac{1}{3} (-y^6 - y^3 + 6y^2 - 12y + 8) dy \\ &= \int_{-2}^1 \left(-\frac{1}{3}y^6 - \frac{1}{3}y^3 + 2y^2 - 4y + \frac{8}{3} \right) dy = \left[-\frac{1}{21}y^7 - \frac{1}{12}y^4 + \frac{2}{3}y^3 - 2y^2 + \frac{8}{3}y \right]_{-2}^1 \\ &= \left[-\frac{1}{21} - \frac{1}{12} + \frac{2}{3} - 2 + \frac{8}{3} \right] - \left[-\frac{1}{21} \cdot (-128) - \frac{1}{12} \cdot 16 + \frac{2}{3} \cdot (-8) - 2 \cdot 4 + \frac{8}{3} \cdot (-2) \right] \\ &= -\frac{1}{21} - \frac{1}{12} + \frac{2}{3} - 2 + \frac{8}{3} - \frac{128}{21} + \frac{4}{3} + \frac{16}{3} + 8 + \frac{16}{3} = \boxed{\frac{423}{28}}. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x \cdot x^2 dA = \int_{-2}^1 \int_{y-2}^{-y^2} x^3 dx dy = \int_{-2}^1 \left[\frac{x^4}{4} \right]_{y-2}^{-y^2} dy \\ &= \int_{-2}^1 \frac{1}{4} [(-y^2)^4 - (y-2)^4] dy = \int_{-2}^1 \frac{1}{4} (y^8 - y^4 + 8y^3 - 24y^2 + 32y - 16) dy \\ &= \int_{-2}^1 \left(\frac{1}{4}y^8 - \frac{1}{4}y^4 + 2y^3 - 6y^2 + 8y - 4 \right) dy = \left[\frac{1}{36}y^9 - \frac{1}{20}y^5 + \frac{1}{2}y^4 - 2y^3 + 4y^2 - 4y \right]_{-2}^1 \\ &= \left[\frac{1}{36} - \frac{1}{20} + \frac{1}{2} - 2 + 4 - 4 \right] - \left[\frac{1}{36} \cdot (-512) - \frac{1}{20} \cdot (-32) + \frac{1}{2} \cdot 16 - 2 \cdot (-8) + 4 \cdot 4 - 4 \cdot (-2) \right] \\ &= \frac{1}{36} - \frac{1}{20} + \frac{1}{2} - 2 + 4 - 4 + \frac{128}{9} - \frac{8}{5} - 8 - 16 - 16 - 8 = -\frac{369}{10}, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{-369/10}{423/28} = -\frac{574}{235} \approx -2.443.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R y \cdot x^2 dA = \int_{-2}^1 \int_{y-2}^{-y^2} yx^2 dx dy = \int_{-2}^1 y \left[\frac{x^3}{3} \right]_{y-2}^{-y^2} dy \\ &= \int_{-2}^1 \frac{1}{3} y [(-y^2)^3 - (y-2)^3] dy = \int_{-2}^1 \frac{1}{3} y (-y^6 - y^3 + 6y^2 - 12y + 8) dy \\ &= \int_{-2}^1 \left(-\frac{1}{3}y^7 - \frac{1}{3}y^4 + 2y^3 - 4y^2 + \frac{8}{3}y \right) dy = \left[-\frac{1}{24}y^8 - \frac{1}{15}y^5 + \frac{1}{2}y^4 - \frac{4}{3}y^3 + \frac{4}{3}y^2 \right]_{-2}^1 \\ &= \left[-\frac{1}{24} - \frac{1}{15} + \frac{1}{2} - \frac{4}{3} + \frac{4}{3} \right] - \left[-\frac{1}{24} \cdot 256 - \frac{1}{15} \cdot (-32) + \frac{1}{2} \cdot 16 - \frac{4}{3} \cdot (-8) + \frac{4}{3} \cdot 4 \right] \\ &= -\frac{1}{24} - \frac{1}{15} + \frac{1}{2} - \frac{4}{3} + \frac{4}{3} + \frac{32}{3} - \frac{32}{15} - 8 - \frac{32}{3} - \frac{16}{3} = -\frac{603}{40}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{-603/40}{423/28} = -\frac{469}{470} \approx -0.998.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \boxed{\left(-\frac{574}{235}, -\frac{469}{470} \right)}$.

34. The region R enclosed by the line $x - 2y + 1 = 0$, which is equivalent to $y = \frac{x+1}{2}$, and the parabola $y = x^2$ is shown in the figure below. The graphs intersect at the points where

$$x^2 = \frac{x+1}{2}, \quad \text{so } 2x^2 - x - 1 = 0, \quad \text{so } (2x+1)(x-1) = 0, \quad \text{so } x = -\frac{1}{2}, 1.$$

Notice that R is an x -simple region: it is bounded between $y = x^2$ and $y = \frac{1}{2}(x+1)$, $-\frac{1}{2} \leq x \leq 1$.

Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R (2x + 8y + 2) dA \\
 &= \int_{-1/2}^1 \int_{x^2}^{(x+1)/2} (2x + 8y + 2) dy dx = \int_{-1/2}^1 [2xy + 4y^2 + 2y]_{x^2}^{(x+1)/2} dx \\
 &= \int_{-1/2}^1 \left\{ \left[2x \cdot \frac{x+1}{2} + 4 \left(\frac{x+1}{2} \right)^2 + 2 \cdot \frac{x+1}{2} \right] - \left[2x \cdot x^2 + 4(x^2)^2 + 2 \cdot x^2 \right] \right\} dx \\
 &= \int_{-1/2}^1 [(x^2 + x + x^2 + 2x + 1 + x + 1) - (2x^3 + 4x^4 + 2x^2)] dx \\
 &= \int_{-1/2}^1 (-4x^4 - 2x^3 + 4x + 2) dx = \left[-\frac{4}{5}x^5 - \frac{1}{2}x^4 + 2x^2 + 2x \right]_{-1/2}^1 \\
 &= \left[-\frac{4}{5} - \frac{1}{2} + 2 + 2 \right] - \left[-\frac{4}{5} \cdot \left(-\frac{1}{32} \right) - \frac{1}{2} \cdot \frac{1}{16} + 2 \cdot \frac{1}{4} + 2 \cdot \left(-\frac{1}{2} \right) \right] \\
 &= -\frac{4}{5} - \frac{1}{2} + 2 + 2 - \frac{1}{40} + \frac{1}{32} - \frac{1}{2} + 1 = \frac{513}{160}.
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R x(2x + 8y + 2) dA \\
 &= \int_{-1/2}^1 \int_{x^2}^{(x+1)/2} (2x^2 + 8xy + 2x) dy dx = \int_{-1/2}^1 [2x^2y + 4xy^2 + 2xy]_{x^2}^{(x+1)/2} dx \\
 &= \int_{-1/2}^1 \left\{ \left[2x^2 \cdot \frac{x+1}{2} + 4x \left(\frac{x+1}{2} \right)^2 + 2x \cdot \frac{x+1}{2} \right] - \left[2x^2 \cdot x^2 + 4x(x^2)^2 + 2x \cdot x^2 \right] \right\} dx \\
 &= \int_{-1/2}^1 [(x^3 + x^2 + x^3 + 2x^2 + x + x^2 + x) - (2x^4 + 4x^5 + 2x^3)] dx \\
 &= \int_{-1/2}^1 (-4x^5 - 2x^4 + 4x^2 + 2x) dx = \left[-\frac{2}{3}x^6 - \frac{2}{5}x^5 + \frac{4}{3}x^3 + x^2 \right]_{-1/2}^1 \\
 &= \left[-\frac{2}{3} - \frac{2}{5} + \frac{4}{3} + 1 \right] - \left[-\frac{2}{3} \cdot \frac{1}{64} - \frac{2}{5} \cdot \left(-\frac{1}{32} \right) + \frac{4}{3} \cdot \left(-\frac{1}{8} \right) + \frac{1}{4} \right] \\
 &= -\frac{2}{3} - \frac{2}{5} + \frac{4}{3} + 1 + \frac{1}{96} - \frac{1}{80} + \frac{1}{6} - \frac{1}{4} = \frac{189}{160},
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{189/160}{513/160} = \frac{7}{19} \approx 0.368.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x, y) dA = \iint_R y(2x + 8y + 2) dA \\
 &= \int_{-1/2}^1 \int_{x^2}^{(x+1)/2} (2xy + 8y^2 + 2y) dy dx = \int_{-1/2}^1 \left[xy^2 + \frac{8}{3}y^3 + y^2 \right]_{x^2}^{(x+1)/2} dx \\
 &= \int_{-1/2}^1 \left\{ \left[x \cdot \left(\frac{x+1}{2} \right)^2 + \frac{8}{3} \left(\frac{x+1}{2} \right)^3 + \left(\frac{x+1}{2} \right)^2 \right] - \left[x \cdot (x^2)^2 + \frac{8}{3} (x^2)^3 + (x^2)^2 \right] \right\} dx \\
 &= \int_{-1/2}^1 \left[\left(\frac{1}{4}x^3 + \frac{1}{2}x^2 + \frac{1}{4}x + \frac{1}{3}x^3 + x^2 + x + \frac{1}{3} + \frac{1}{4}x^2 + \frac{1}{2}x + \frac{1}{4} \right) - \left(x^5 + \frac{8}{3}x^6 + x^4 \right) \right] dx \\
 &= \int_{-1/2}^1 \left(-\frac{8}{3}x^6 - x^5 - x^4 + \frac{7}{12}x^3 + \frac{7}{4}x^2 + \frac{7}{4}x + \frac{7}{12} \right) dx \\
 &= \left[-\frac{8}{21}x^7 - \frac{1}{6}x^6 - \frac{1}{5}x^5 + \frac{7}{48}x^4 + \frac{7}{12}x^3 + \frac{7}{8}x^2 + \frac{7}{12}x \right]_{-1/2}^1 \\
 &= \left[-\frac{8}{21} - \frac{1}{6} - \frac{1}{5} + \frac{7}{48} + \frac{7}{12} + \frac{7}{8} + \frac{7}{12} \right] \\
 &\quad - \left[-\frac{8}{21} \cdot \left(-\frac{1}{128} \right) - \frac{1}{6} \cdot \frac{1}{64} - \frac{1}{5} \cdot \left(-\frac{1}{32} \right) + \frac{7}{48} \cdot \frac{1}{16} + \frac{7}{12} \cdot \left(-\frac{1}{8} \right) + \frac{7}{8} \cdot \frac{1}{4} + \frac{7}{12} \cdot \left(-\frac{1}{2} \right) \right] \\
 &= -\frac{8}{21} - \frac{1}{6} - \frac{1}{5} + \frac{7}{48} + \frac{7}{12} + \frac{7}{8} + \frac{7}{12} - \frac{1}{336} + \frac{1}{384} - \frac{1}{160} - \frac{7}{768} + \frac{7}{96} - \frac{7}{32} + \frac{7}{24} = \frac{14067}{8960},
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{14067/8960}{513/160} = \frac{521}{1064} \approx 0.490.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{7}{19}, \frac{521}{1064} \right) \approx (0.368, 0.490)$.

35. The region R enclosed by the parabola $bx^2 = a^2y$, or $y = \frac{b}{a^2}x^2$, and the line $ay = bx$, or $y = \frac{b}{a}x$, is shown in the figure below. The graphs intersect at the points where

$$\frac{b}{a^2}x^2 = \frac{b}{a}x \quad \text{so} \quad \frac{b}{a^2}x^2 - \frac{b}{a}x = 0, \quad \text{so} \quad \frac{b}{a}x \left(\frac{1}{a}x - 1 \right) = 0, \quad \text{so} \quad x = 0, a.$$

Notice that R is an x -simple region: it is bounded between $y = \frac{b}{a^2}x^2$ and $y = \frac{b}{a}x$, $0 \leq x \leq a$. Assuming that the lamina is homogeneous with constant mass density ρ , its mass M can be found as a double

integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R \rho dA = \rho \int_0^a \int_{bx^2/a^2}^{bx/a} dy dx = \rho \int_0^a [y]_{bx^2/a^2}^{bx/a} dx \\
 &= \rho \int_0^a \left(\frac{bx}{a} - \frac{bx^2}{a^2} \right) dx = \rho \int_0^a \frac{b}{a} \left(x - \frac{x^2}{a} \right) dx = \frac{b\rho}{a} \left[\frac{x^2}{2} - \frac{x^3}{3a} \right]_0^a \\
 &= \frac{b\rho}{a} \left[\left(\frac{a^2}{2} - \frac{a^3}{3a} \right) - (0 - 0) \right] = \frac{b\rho}{a} \cdot a^2 \left(\frac{1}{2} - \frac{1}{3} \right) = ab\rho \cdot \frac{1}{6} = \frac{ab\rho}{6}.
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R x\rho dA = \rho \int_0^a \int_{bx^2/a^2}^{bx/a} x dy dx = \rho \int_0^a [xy]_{bx^2/a^2}^{bx/a} dx \\
 &= \rho \int_0^a x \left(\frac{bx}{a} - \frac{bx^2}{a^2} \right) dx = \rho \int_0^a \frac{b}{a} \left(x^2 - \frac{x^3}{a} \right) dx = \frac{b\rho}{a} \left[\frac{x^3}{3} - \frac{x^4}{4a} \right]_0^a \\
 &= \frac{b\rho}{a} \left[\left(\frac{a^3}{3} - \frac{a^4}{4a} \right) - (0 - 0) \right] = \frac{b\rho}{a} \cdot a^3 \left(\frac{1}{3} - \frac{1}{4} \right) = a^2 b\rho \cdot \frac{1}{12} = \frac{a^2 b\rho}{12},
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{a^2 b\rho/12}{ab\rho/6} = \frac{a}{2}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x, y) dA = \iint_R y\rho dA = \rho \int_0^a \int_{bx^2/a^2}^{bx/a} y dy dx = \rho \int_0^a \left[\frac{y^2}{2} \right]_{bx^2/a^2}^{bx/a} dx \\
 &= \rho \int_0^a \left(\frac{(bx/a)^2}{2} - \frac{(bx^2/a^2)^2}{2} \right) dx = \frac{\rho}{2} \int_0^a \left(\frac{b^2 x^2}{a^2} - \frac{b^2 x^4}{a^4} \right) dx \\
 &= \frac{\rho}{2} \int_0^a \frac{b^2}{a^2} \left(x^2 - \frac{x^4}{a^2} \right) dx = \frac{b^2 \rho}{2a^2} \left[\frac{x^3}{3} - \frac{x^5}{5a^2} \right]_0^a \\
 &= \frac{b^2 \rho}{2a^2} \left[\left(\frac{a^3}{3} - \frac{a^5}{5a^2} \right) - (0 - 0) \right] = \frac{b^2 \rho}{2a^2} \cdot a^3 \left(\frac{1}{3} - \frac{1}{5} \right) = \frac{ab^2 \rho}{2} \cdot \frac{2}{15} = \frac{ab^2 \rho}{15},
 \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{ab^2 \rho/15}{ab\rho/6} = \frac{2b}{5}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{a}{2}, \frac{2b}{5} \right)$.

36. To find the mass and the moments of mass of the lamina, we will need to set up certain double integrals, and we can evaluate each of them using the computer algebra system *Mathematica*.

The region R enclosed by the graph of $y = \ln x$, the x -axis, and the vertical line $x = e^2$ is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = \ln x$, $1 \leq x \leq e^2$. Assuming that the lamina is homogeneous with constant mass density ρ , its mass M can be found as a double integral:

$$M = \iint_R \rho(x, y) dA = \iint_R \rho dA = \rho \int_1^{e^2} \int_0^{\ln x} dy dx = (1 + e^2)\rho.$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$M_y = \iint_R x\rho(x, y) dA = \iint_R x\rho dA = \rho \int_1^{e^2} \int_0^{\ln x} x dy dx = \frac{1}{4}(1 + 3e^4)\rho.$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{\frac{1}{4}(1 + 3e^4)\rho}{(1 + e^2)\rho} = \frac{1 + 3e^4}{4(1 + e^2)} \approx 4.911.$$

Similarly, the moment of mass about the x -axis is

$$M_x = \iint_R y\rho(x, y) dA = \iint_R y\rho dA = \rho \int_1^{e^2} \int_0^{\ln x} y dy dx = (-1 + e^2)\rho.$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{(-1 + e^2)\rho}{(1 + e^2)\rho} = \frac{-1 + e^2}{1 + e^2} \approx 0.762.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{1 + 3e^4}{4(1 + e^2)}, \frac{-1 + e^2}{1 + e^2} \right) \approx (4.911, 0.762)$.

37. (a) If we place this washer, whose inner radius is a and outer radius is b , in the polar coordinate system so that its center is at the pole, then it occupies the region R given by $a \leq r \leq b$, $0 \leq \theta \leq 2\pi$; see the figure below. The mass density of the washer is inversely proportional to the square of the distance from the center; that is, $\rho(r, \theta) = \frac{k}{r^2}$, where k is a constant coefficient of proportionality. Then the mass M of the washer can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R \frac{k}{r^2} \cdot r dr d\theta = k \int_0^{2\pi} \int_a^b \frac{1}{r} dr d\theta \\ &= k \int_0^{2\pi} [\ln |r|]_a^b d\theta = k \int_0^{2\pi} (\ln b - \ln a) d\theta = k \int_0^{2\pi} \ln \left(\frac{b}{a} \right) d\theta \\ &= k \ln \left(\frac{b}{a} \right) \int_0^{2\pi} d\theta = k \ln \left(\frac{b}{a} \right) [\theta]_0^{2\pi} = k \ln \left(\frac{b}{a} \right) \cdot (2\pi - 0) = \boxed{2\pi k \ln \left(\frac{b}{a} \right)}. \end{aligned}$$

If we keep b fixed, but let $a \rightarrow 0^+$, then $\frac{b}{a} \rightarrow \infty$, and so

$$\lim_{a \rightarrow 0^+} M = \lim_{a \rightarrow 0^+} 2\pi k \ln \left(\frac{b}{a} \right) = 2\pi k \lim_{a \rightarrow 0^+} \ln \left(\frac{b}{a} \right) = \infty.$$

In other words, if the radius a of this washer's hole decreases getting closer and closer to 0, its mass will be growing arbitrarily large.

- (b) The moment of inertia of this washer about its center, that is about the origin, is

$$\begin{aligned} I_O &= \iint_R (x^2 + y^2) \rho(x, y) dA = \iint_R r^2 \cdot \frac{k}{r^2} \cdot r dr d\theta = k \int_0^{2\pi} \int_a^b r dr d\theta \\ &= k \int_0^{2\pi} \left[\frac{r^2}{2} \right]_a^b d\theta = \frac{k}{2} \int_0^{2\pi} (b^2 - a^2) d\theta = \frac{k(b^2 - a^2)}{2} \int_0^{2\pi} d\theta \\ &= \frac{k(b^2 - a^2)}{2} [\theta]_0^{2\pi} = \frac{k(b^2 - a^2)}{2} \cdot (2\pi - 0) = \boxed{\pi k(b^2 - a^2)}. \end{aligned}$$

If we keep b fixed, but let $a \rightarrow 0^+$, then

$$\lim_{a \rightarrow 0^+} I_O = \lim_{a \rightarrow 0^+} \pi k(b^2 - a^2) = \pi k b^2.$$

In other words, if the radius a of this washer's hole decreases getting closer and closer to 0, the moment of inertia of the washer about its center will remain finite approaching the value of $\pi k b^2$.

38. (a) The graphs of the limaçon $r = 3 + 2 \cos \theta$ and the circle $r = 2$ are shown in the figure (a) below.

- (b) The region R lying inside the limaçon $r = 3 + 2 \cos \theta$ and outside the circle $r = 2$ is shown in the figure (b) above. The graphs intersect at the points where

$$3 + 2 \cos \theta = 2, \quad \text{so} \quad 2 \cos \theta = -1, \quad \text{so} \quad \cos \theta = -\frac{1}{2}, \quad \text{so} \quad \theta = \pm \frac{2\pi}{3}.$$

So R is given by $2 \leq r \leq 3 + 2 \cos \theta$, $-\frac{2\pi}{3} \leq \theta \leq \frac{2\pi}{3}$. The mass density of the lamina is inversely proportional to the square of the distance from the origin (pole); that is, $\rho(r, \theta) = \frac{k}{r^2}$, where k is a constant coefficient of proportionality. Then the moment of inertia of the lamina about the x -axis can be found as a double integral:

$$I_x = \iint_R y^2 \rho(x, y) dA = \iint_R r^2 \sin^2 \theta \cdot \frac{k}{r^2} \cdot r dr d\theta = \boxed{k \int_{-2\pi/3}^{2\pi/3} \int_2^{3+2\cos\theta} r \sin^2 \theta dr d\theta}.$$

(c) Using the computer algebra system *Mathematica*, we find that the value of this double integral is

$$I_x = k \int_{-2\pi/3}^{2\pi/3} \int_2^{3+2\cos\theta} r \sin^2 \theta dr d\theta = \boxed{k \left(\frac{33\sqrt{3}}{16} + 2\pi \right)}.$$

39. Place this rectangular lamina on the coordinate plane so that one of its vertices is at the origin and two of its sides lie on the positive x - and y -axes. If the width of the lamina is a and the height is b , the region R it occupies is given by $0 \leq x \leq a$, $0 \leq y \leq b$; see the figure below. The area of this rectangle is $A = ab$. Assuming the lamina is homogeneous, its mass density is ρ , a constant, and the mass of the lamina is $M = \rho A = \rho \cdot ab = ab\rho$.

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x \rho(x, y) dA = \iint_R x \rho dy dx = \rho \int_0^a \int_0^b x dy dx = \rho \int_0^a x [y]_0^b dx \\ &= \rho \int_0^a x(b-0) dx = b\rho \int_0^a x dx = b\rho \left[\frac{x^2}{2} \right]_0^a = b\rho \left(\frac{a^2}{2} - 0 \right) = \frac{a^2 b \rho}{2}, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{a^2 b \rho / 2}{ab\rho} = \frac{a}{2}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y \rho(x, y) dA = \iint_R y \rho dy dx = \rho \int_0^a \int_0^b y dy dx = \rho \int_0^a \left[\frac{y^2}{2} \right]_0^b dx \\ &= \rho \int_0^a \left(\frac{b^2}{2} - 0 \right) dx = \frac{b^2 \rho}{2} \int_0^a dx = \frac{b^2 \rho}{2} [x]_0^a = \frac{b^2 \rho}{2} (a - 0) = \frac{ab^2 \rho}{2}, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{ab^2 \rho / 2}{ab\rho} = \frac{b}{2}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{a}{2}, \frac{b}{2} \right)$, which is precisely the geometrical center of the rectangle, that is the point where its diagonals intersect.

40. Place this lamina on the coordinate plane so that its right-angle vertex is at the origin, the base of length b lies on the positive x -axis, and the height of length h lies on the positive y -axis. The hypotenuse of the triangle has $(b, 0)$ and $(0, h)$ as its intercepts, so its equation is $\frac{x}{b} + \frac{y}{h} = 1$ or $y = h\left(1 - \frac{x}{b}\right)$. So the region R that the lamina occupies is given by $0 \leq y \leq h\left(1 - \frac{x}{b}\right)$, $0 \leq x \leq b$; see the figure below. The area of the triangle is $A = \frac{1}{2}bh$. Assuming the lamina is homogeneous, its mass density is ρ , a constant, and the mass of the lamina is $m = \rho A = \rho \cdot \frac{1}{2}bh = \frac{bh\rho}{2}$.

The moment of inertia of the lamina about the base, that is about the x -axis, can be found as a double integral:

$$\begin{aligned}
 I_x &= \iint_R y^2 \rho(x, y) dA = \iint_R y^2 \rho dy dx = \rho \int_0^b \int_0^{h(1-x/b)} y^2 dy dx = \rho \int_0^b \left[\frac{y^3}{3} \right]_0^{h(1-x/b)} dx \\
 &= \frac{\rho}{3} \int_0^b \left\{ \left[h\left(1 - \frac{x}{b}\right) \right]^3 - 0 \right\} dx = \frac{\rho}{3} \int_0^b h^3 \left(1 - \frac{x}{b}\right)^3 dx = \frac{h^3 \rho}{3} \int_0^b \left(1 - \frac{3x}{b} + \frac{3x^2}{b^2} - \frac{x^3}{b^3}\right) dx \\
 &= \frac{h^3 \rho}{3} \left[x - \frac{3x^2}{2b} + \frac{x^3}{b^2} - \frac{x^4}{4b^3} \right]_0^b = \frac{h^3 \rho}{3} \left[\left(b - \frac{3b^2}{2b} + \frac{b^3}{b^2} - \frac{b^4}{4b^3} \right) - 0 \right] \\
 &= \frac{h^3 \rho}{3} \cdot b \left(1 - \frac{3}{2} + 1 - \frac{1}{4} \right) = \frac{bh^3 \rho}{3} \cdot \frac{1}{4} = \frac{bh^3 \rho}{12} = \frac{bh\rho}{2} \cdot \frac{h^2}{6} = m \cdot \frac{h^2}{6} = \frac{1}{6}mh^2,
 \end{aligned}$$

as desired.

Challenge Problems

41. Consider a triangular lamina occupying the region R positioned as shown in the figure (a) below. The vertices of the triangle are $A(a, 0)$, $B(b, 0)$, and $C(0, c)$.

First, let us find the point $M(x_M, y_M)$ of intersection of the medians of the triangle. The midpoint of the base AB is at the point $K\left(\frac{a+b}{2}, 0\right)$. We know from geometry that all three medians in a triangle intersect at a single point, which divides each median in the ratio of 2 : 1 counting from the vertex. So the point $M(x_M, y_M)$ divides the segment CK in the ratio of 2 : 1; see figure (b) below. In other words, the point M lies on the segment CK so that MK is one third of the entire segment CK ,

and so the coordinates of M satisfy

$$\begin{aligned}
 x_M - x_K &= \frac{1}{3}(x_C - x_K) & y_M - y_K &= \frac{1}{3}(y_C - y_K) \\
 x_M - \frac{a+b}{2} &= \frac{1}{3}\left(0 - \frac{a+b}{2}\right) & y_M - 0 &= \frac{1}{3}(c - 0) \\
 x_M &= \frac{a+b}{2} - \frac{1}{3} \cdot \frac{a+b}{2} & y_M &= \frac{1}{3} \cdot c \\
 x_M &= \frac{a+b}{2} \cdot \frac{2}{3} & y_M &= \frac{c}{3} \\
 x_M &= \frac{a+b}{3}
 \end{aligned}$$

The medians of this triangle intersect at the point $M\left(\frac{a+b}{3}, \frac{c}{3}\right)$.

(a)

(b)

Now we proceed to finding the center of mass of this triangular lamina. Notice that R is a y -simple region. The side AC of the triangle has $(a, 0)$ and $(0, c)$ as its intercepts, so its equation is $\frac{x}{a} + \frac{y}{c} = 1$ or $x = a\left(1 - \frac{y}{c}\right)$. The side BC of the triangle has $(b, 0)$ and $(0, c)$ as its intercepts, so its equation is $\frac{x}{b} + \frac{y}{c} = 1$ or $x = b\left(1 - \frac{y}{c}\right)$. So the region R that the lamina occupies is given by $a\left(1 - \frac{y}{c}\right) \leq x \leq b\left(1 - \frac{y}{c}\right)$, $0 \leq y \leq c$. The area of the triangle is $A = \frac{1}{2} \cdot AB \cdot CO = \frac{1}{2}(b-a)c = \frac{(b-a)c}{2}$. Assuming the lamina is homogeneous, its mass density is ρ , a constant, and the mass of the lamina is $M = \rho A = \rho \cdot \frac{(b-a)c}{2} = \frac{(b-a)c\rho}{2}$.

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned}
 M_y &= \iint_R x\rho(x, y) dA = \iint_R x\rho dx dy = \rho \int_0^c \int_{a(1-y/c)}^{b(1-y/c)} x dx dy = \rho \int_0^c \left[\frac{x^2}{2} \right]_{a(1-y/c)}^{b(1-y/c)} dy \\
 &= \frac{\rho}{2} \int_0^c \left[b^2 \left(1 - \frac{y}{c}\right)^2 - a^2 \left(1 - \frac{y}{c}\right)^2 \right] dy = \frac{\rho}{2} \int_0^c (b^2 - a^2) \left(1 - \frac{y}{c}\right)^2 dy \\
 &= \frac{(b^2 - a^2)\rho}{2} \int_0^c \left(1 - \frac{2y}{c} + \frac{y^2}{c^2}\right) dy = \frac{(b^2 - a^2)\rho}{2} \left[y - \frac{y^2}{c} + \frac{y^3}{3c^2} \right]_0^c \\
 &= \frac{(b^2 - a^2)\rho}{2} \left[\left(c - \frac{c^2}{c} + \frac{c^3}{3c^2} \right) - 0 \right] = \frac{(b^2 - a^2)\rho}{2} \cdot \frac{c}{3} = \frac{(b^2 - a^2)c\rho}{6}.
 \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{(b^2 - a^2)c\rho/6}{(b-a)c\rho/2} = \frac{b^2 - a^2}{3(b-a)} = \frac{(b-a)(b+a)}{3(b-a)} = \frac{b+a}{3} = \frac{a+b}{3}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned}
 M_x &= \iint_R y\rho(x, y) dA = \iint_R y\rho dx dy = \rho \int_0^c \int_{a(1-y/c)}^{b(1-y/c)} y dx dy = \rho \int_0^c y [x]_{a(1-y/c)}^{b(1-y/c)} dy \\
 &= \rho \int_0^c y \left[b \left(1 - \frac{y}{c} \right) - a \left(1 - \frac{y}{c} \right) \right] dy = \rho \int_0^c y(b-a) \left(1 - \frac{y}{c} \right) dy = (b-a)\rho \int_0^c \left(y - \frac{y^2}{c} \right) dy \\
 &= (b-a)\rho \left[\frac{y^2}{2} - \frac{y^3}{3c} \right]_0^c = (b-a)\rho \left[\left(\frac{c^2}{2} - \frac{c^3}{3c} \right) - 0 \right] = (b-a)\rho \cdot \frac{c^2}{6} = \frac{(b-a)c^2\rho}{6}.
 \end{aligned}$$

so $\bar{y} = \frac{M_x}{M} = \frac{(b-a)c^2\rho/6}{(b-a)c\rho/2} = \frac{c}{3}$.

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{a+b}{3}, \frac{c}{3} \right)$, which is precisely the point M of intersection of the medians of the triangle.

42. Suppose a homogeneous lamina of constant mass density ρ occupies a region R in the xy -plane, and let $A = \iint_R dA$ be the area of the region R . Then the mass of the lamina is

$$M = \iint_R \rho(x, y) dA = \iint_R \rho dA = \rho \iint_R dA = \rho A.$$

The moment of mass of the lamina about the y -axis is

$$M_y = \iint_R x\rho(x, y) dA = \iint_R x\rho dA = \rho \iint_R x dA,$$

and so the first coordinate of the center of mass of the lamina is $\bar{x} = \frac{M_y}{M} = \frac{\rho \iint_R x dA}{\rho A} = \frac{1}{A} \iint_R x dA$.

On the other hand, the average value of the function $f(x, y) = x$ over the region R is $\frac{1}{A} \iint_R f(x, y) dA = \frac{1}{A} \iint_R x dA = \bar{x}$, as desired.

Similarly, the moment of mass of the lamina about the x -axis is

$$M_x = \iint_R y\rho(x, y) dA = \iint_R y\rho dA = \rho \iint_R y dA,$$

and so the second coordinate of the center of mass of the lamina is $\bar{y} = \frac{M_x}{M} = \frac{\rho \iint_R y dA}{\rho A} = \frac{1}{A} \iint_R y dA$.

But the average value of the function $g(x, y) = y$ over R is $\frac{1}{A} \iint_R g(x, y) dA = \frac{1}{A} \iint_R y dA = \boxed{\bar{y}}$.

43. (a) Consider the thin flat plate shown in the figure in Problem 43; let D be the region in the xy -plane that it occupies. Note that for any point in the xy -plane, in particular for any point on the plate, the distance from this point to the z -axis is r , the distance from the origin, so

$$\begin{aligned}
 I_z &= I_O = \iint_D r^2 \rho(x, y) dA = \iint_D (x^2 + y^2) \rho(x, y) dA \\
 &= \iint_D x^2 \rho(x, y) dA + \iint_D y^2 \rho(x, y) dA = I_y + I_x = I_x + I_y,
 \end{aligned}$$

as desired.

- (b) Place the disk in the coordinate space so that it lies in the xy -plane with its center at the origin; see figure (a) below. Then the axis through its center and perpendicular to its plane is the z -axis, and two of its diameters lie on the x - and y -axes. Assuming the disk is homogeneous, due to symmetry its moment of inertia I_d about any diameter is the same. Then using part (a), we find that

$$2I_d = I_x + I_y = I_z = \frac{mR^2}{2}, \quad \text{so} \quad I_d = \frac{1}{2} \cdot \frac{mR^2}{2} = \boxed{\frac{mR^2}{4}}.$$

- (c) Place the disk in the coordinate space so that it lies in the xy -plane, its diameter lies on the x -axis, and its edge contains the origin; see figure (b) above. This way the y -axis is an axis tangent to the disk's edge. In the xy -plane, the equation of the disk's boundary in polar coordinates is $r = 2R \cos \theta$, and the region D that the disk occupies in the xy -plane is given by $0 \leq r \leq 2R \cos \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then the moment of inertia of the disk about the y -axis is

$$\begin{aligned} I_y &= \iint_D x^2 \rho(x, y) dA = \int_{-\pi/2}^{\pi/2} \int_0^{2R \cos \theta} (r \cos \theta)^2 \cdot \rho \cdot r dr d\theta \\ &= \rho \int_{-\pi/2}^{\pi/2} \int_0^{2R \cos \theta} r^3 \cos^2 \theta dr d\theta = \rho \int_{-\pi/2}^{\pi/2} \cos^2 \theta \cdot \left[\frac{r^4}{4} \right]_0^{2R \cos \theta} d\theta \\ &= \rho \int_{-\pi/2}^{\pi/2} \cos^2 \theta \cdot (4R^4 \cos^4 \theta - 0) d\theta = 4R^4 \rho \int_{-\pi/2}^{\pi/2} \cos^6 \theta d\theta \\ &= 4R^4 \rho \int_{-\pi/2}^{\pi/2} (\cos^2 \theta)^3 d\theta = 4R^4 \rho \int_{-\pi/2}^{\pi/2} \left[\frac{1}{2}(1 + \cos(2\theta)) \right]^3 d\theta \\ &= 4R^4 \rho \int_{-\pi/2}^{\pi/2} \frac{1}{8} (1 + 3 \cos(2\theta) + 3 \cos^2(2\theta) + \cos^3(2\theta)) d\theta \\ &= \frac{R^4 \rho}{2} \int_{-\pi/2}^{\pi/2} \left[1 + 3 \cos(2\theta) + 3 \cdot \frac{1}{2}(1 + \cos(4\theta)) + \cos^3(2\theta) \right] d\theta \\ &= \frac{R^4 \rho}{2} \int_{-\pi/2}^{\pi/2} \left(\frac{5}{2} + 3 \cos(2\theta) + \frac{3}{2} \cos(4\theta) + \cos^3(2\theta) \right) d\theta \\ &= \frac{R^4 \rho}{2} \left(\frac{5}{2} \int_{-\pi/2}^{\pi/2} d\theta + 3 \int_{-\pi/2}^{\pi/2} \cos(2\theta) d\theta + \frac{3}{2} \int_{-\pi/2}^{\pi/2} \cos(4\theta) d\theta + \int_{-\pi/2}^{\pi/2} \cos^3(2\theta) d\theta \right). \end{aligned}$$

The first three integrals in parentheses can be evaluated directly:

$$\begin{aligned}\frac{5}{2} \int_{-\pi/2}^{\pi/2} d\theta &= \frac{5}{2} [\theta]_{-\pi/2}^{\pi/2} = \frac{5}{2} \left[\frac{\pi}{2} - \left(-\frac{\pi}{2} \right) \right] = \frac{5}{2} \cdot \pi = \frac{5\pi}{2}; \\ 3 \int_{-\pi/2}^{\pi/2} \cos(2\theta) d\theta &= 3 \left[\frac{\sin(2\theta)}{2} \right]_{-\pi/2}^{\pi/2} = \frac{3}{2} [\sin \pi - \sin(-\pi)] = \frac{3}{2} \cdot (0 - 0) = 0; \\ \frac{3}{2} \int_{-\pi/2}^{\pi/2} \cos(4\theta) d\theta &= \frac{3}{2} \left[\frac{\sin(4\theta)}{4} \right]_{-\pi/2}^{\pi/2} = \frac{3}{8} [\sin(2\pi) - \sin(-2\pi)] = \frac{3}{8} \cdot (0 - 0) = 0.\end{aligned}$$

To evaluate the last integral in parentheses, we rewrite it in the form

$$\int_{-\pi/2}^{\pi/2} \cos^3(2\theta) d\theta = \int_{-\pi/2}^{\pi/2} \cos^2(2\theta) \cdot \cos(2\theta) d\theta = \int_{-\pi/2}^{\pi/2} (1 - \sin^2(2\theta)) \cdot \cos(2\theta) d\theta,$$

and make a substitution $u = \sin(2\theta)$; then $du = 2 \cos(2\theta) d\theta$, so $\cos(2\theta) d\theta = \frac{du}{2}$. We also change the limits of integration: if $\theta = -\frac{\pi}{2}$, then $u = \sin(-\pi) = 0$; if $\theta = \frac{\pi}{2}$, then $u = \sin \pi = 0$. So

$$\int_{-\pi/2}^{\pi/2} \cos^3(2\theta) d\theta = \int_{-\pi/2}^{\pi/2} (1 - \sin^2(2\theta)) \cdot \cos(2\theta) d\theta = \int_0^0 (1 - u^2) \frac{du}{2} = \frac{1}{2} \int_0^0 (1 - u^2) du = 0.$$

Substituting these values back into the computation of I_y , we obtain

$$I_y = \frac{R^4 \rho}{2} \left(\frac{5\pi}{2} + 0 + 0 + 0 \right) = \frac{5\pi R^4 \rho}{4}.$$

Let A be the area of the disk: $A = \pi R^2$. Since the disk is homogeneous of mass density ρ , its mass is $m = \rho A = \rho \pi R^2$. Then the moment of inertia about the y -axis can be expressed as

$$I_y = \frac{5\pi R^4 \rho}{4} = \frac{5R^2 \cdot \pi R^2 \rho}{4} = \frac{5R^2 \cdot m}{4} = \boxed{\frac{5mR^2}{4}}.$$

14.5 Surface Area

Concepts and Vocabulary

1. True, according to formula (1) on page 936 of the textbook.
2. False. The area of the part of the surface $z = f(x, y)$ lying over the closed bounded region R is given by $S = \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA$.

Skill Building

3. The equation of the plane $2x + 2y + z = 6$ can be rewritten as $z = f(x, y) = 6 - 2x - 2y$. The region R is bounded in the first quadrant by the graph of $x^2 + y^2 = 4$ and the coordinate axes; see the figure in Problem 3. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -2$ and $f_y(x, y) = -2$. Since both f_x and f_y are continuous on R , the surface area S of the part of the plane that lies above R is

$$S = \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{(-2)^2 + (-2)^2 + 1} dA = \iint_R 3 dA.$$

Since the region R is bounded by a part of a circle, we switch to polar coordinates. In polar coordinates, R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$. Then

$$\begin{aligned} S &= \iint_R 3 dA = \int_0^{\pi/2} \int_0^2 3 \cdot r dr d\theta = 3 \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_0^2 d\theta \\ &= 3 \int_0^{\pi/2} (2 - 0) d\theta = 6 \int_0^{\pi/2} d\theta = 6 [\theta]_0^{\pi/2} = 6 \left(\frac{\pi}{2} - 0 \right) = \boxed{3\pi}. \end{aligned}$$

4. The equation of the plane $4z - 2x - y = 8$ can be rewritten as $z = f(x, y) = 2 + \frac{x}{2} + \frac{y}{4}$. The region R in the xy -plane is the triangle with the vertices $(0, 0, 0)$, $(1, 0, 0)$, and $(1, 1, 0)$; see the figure in Problem 4. In the xy -plane, R is given by $0 \leq y \leq x$, $0 \leq x \leq 1$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = \frac{1}{2}$ and $f_y(x, y) = \frac{1}{4}$. Since both f_x and f_y are continuous on R , the surface area S of the part of the plane that lies above R is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{\left(\frac{1}{2}\right)^2 + \left(\frac{1}{4}\right)^2 + 1} dA = \iint_R \frac{\sqrt{21}}{4} dA \\ &= \int_0^1 \int_0^x \frac{\sqrt{21}}{4} dy dx = \frac{\sqrt{21}}{4} \int_0^1 [y]_0^x dx = \frac{\sqrt{21}}{4} \int_0^1 (x - 0) dx = \frac{\sqrt{21}}{4} \int_0^1 x dx \\ &= \frac{\sqrt{21}}{4} \left[\frac{x^2}{2} \right]_0^1 = \frac{\sqrt{21}}{4} \left(\frac{1}{2} - 0 \right) = \boxed{\frac{\sqrt{21}}{8}}. \end{aligned}$$

5. The surface $z = f(x, y) = \sqrt{9 - x^2}$ and the rectangular region R in the xy -plane enclosed by the lines $x = 0$, $x = 2$, $y = -1$, and $y = 4$ are shown in the figure below. In the xy -plane, R is given by $0 \leq x \leq 2$, $-1 \leq y \leq 4$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{9 - x^2}}$ and

$f_y(x, y) = 0$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(-\frac{x}{\sqrt{9-x^2}}\right)^2 + 0^2 + 1} \, dA \\
 &= \iint_R \sqrt{\frac{x^2}{9-x^2} + 1} \, dA = \iint_R \sqrt{\frac{9}{9-x^2}} \, dA = \iint_R \frac{3}{\sqrt{9-x^2}} \, dA = 3 \int_{-1}^4 \int_0^2 \frac{1}{\sqrt{9-x^2}} \, dx dy \\
 &= 3 \int_{-1}^4 \left[\sin^{-1} \left(\frac{x}{3} \right) \right]_0^2 dy = 3 \int_{-1}^4 \left[\sin^{-1} \left(\frac{2}{3} \right) - \sin^{-1} 0 \right] dy = 3 \int_{-1}^4 \left[\sin^{-1} \left(\frac{2}{3} \right) - 0 \right] dy \\
 &= 3 \sin^{-1} \left(\frac{2}{3} \right) \int_{-1}^4 dy = 3 \sin^{-1} \left(\frac{2}{3} \right) [y]_{-1}^4 = 3 \sin^{-1} \left(\frac{2}{3} \right) \cdot [4 - (-1)] = \boxed{15 \sin^{-1} \left(\frac{2}{3} \right)}.
 \end{aligned}$$

6. The surface $z = f(x, y) = \sqrt{8-y^2}$ and the rectangular region R in the xy -plane enclosed by the lines $x = 0$, $x = 5$, $y = 0$, and $y = 2$ are shown in the figure below. In the xy -plane, R is given by $0 \leq x \leq 5$, $0 \leq y \leq 2$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = 0$ and $f_y(x, y) = -\frac{y}{\sqrt{8-y^2}}$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{0^2 + \left(-\frac{y}{\sqrt{8-y^2}}\right)^2 + 1} \, dA \\
 &= \iint_R \sqrt{\frac{y^2}{8-y^2} + 1} \, dA = \iint_R \sqrt{\frac{8}{8-y^2}} \, dA = \iint_R \frac{2\sqrt{2}}{\sqrt{8-y^2}} \, dA = 2\sqrt{2} \int_0^5 \int_0^2 \frac{1}{\sqrt{8-y^2}} \, dy dx \\
 &= 2\sqrt{2} \int_0^5 \left[\sin^{-1} \left(\frac{y}{2\sqrt{2}} \right) \right]_0^2 dx = 2\sqrt{2} \int_0^5 \left[\sin^{-1} \left(\frac{1}{\sqrt{2}} \right) - \sin^{-1} 0 \right] dx = 2\sqrt{2} \int_0^5 \left(\frac{\pi}{4} - 0 \right) dx \\
 &= 2\sqrt{2} \cdot \frac{\pi}{4} \int_0^5 dx = \frac{\pi\sqrt{2}}{2} [x]_0^5 = \frac{\pi\sqrt{2}}{2} \cdot (5 - 0) = \boxed{\frac{5\pi\sqrt{2}}{2}}.
 \end{aligned}$$

7. The surface $z = f(x, y) = \frac{2}{3}(x^{3/2} + y^{3/2})$ and the triangular region R in the xy -plane enclosed by the lines $x = 0$, $y = 0$, and $2x + 3y = 6$ are shown in the figures below. In the xy -plane, R is given by $0 \leq y \leq 2 - \frac{2x}{3}$, $0 \leq x \leq 3$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = x^{1/2}$ and $f_y(x, y) = y^{1/2}$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{(x^{1/2})^2 + (y^{1/2})^2 + 1} dA = \iint_R \sqrt{x + y + 1} dA \\
 &= \int_0^3 \int_0^{2-2x/3} (x + y + 1)^{1/2} dy dx = \int_0^3 \left[\frac{2}{3}(x + y + 1)^{3/2} \right]_0^{2-2x/3} dx \\
 &= \frac{2}{3} \int_0^3 \left[\left(x + 2 - \frac{2x}{3} + 1 \right)^{3/2} - (x + 0 + 1)^{3/2} \right] dx = \frac{2}{3} \int_0^3 \left[\left(\frac{x}{3} + 3 \right)^{3/2} - (x + 1)^{3/2} \right] dx \\
 &= \frac{2}{3} \left[3 \cdot \frac{2}{5} \left(\frac{x}{3} + 3 \right)^{5/2} - \frac{2}{5} (x + 1)^{5/2} \right]_0^3 = \frac{2}{3} \cdot \frac{2}{5} \left[3 \left(\sqrt{\frac{x}{3} + 3} \right)^5 - (\sqrt{x + 1})^5 \right]_0^3 \\
 &= \frac{4}{15} \left\{ \left[3(\sqrt{4})^5 - (\sqrt{4})^5 \right] - \left[3(\sqrt{3})^5 - (\sqrt{1})^5 \right] \right\} \\
 &= \frac{4}{15} (96 - 32 - 27\sqrt{3} + 1) = \frac{4}{15} (65 - 27\sqrt{3}) = \boxed{\frac{52}{3} - \frac{36\sqrt{3}}{5}}.
 \end{aligned}$$

(a)

(b)

8. The surface $z = f(x, y) = \frac{2}{3}(x^{3/2} + y^{3/2})$ and the triangular region R in the xy -plane enclosed by the lines $x = 0$, $y = 0$, and $3x + y = 3$ are shown in the figures below. In the xy -plane, R is given by $0 \leq y \leq 3 - 3x$, $0 \leq x \leq 1$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = x^{1/2}$ and

$f_y(x, y) = y^{1/2}$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{(x^{1/2})^2 + (y^{1/2})^2 + 1} dA = \iint_R \sqrt{x + y + 1} dA \\
 &= \int_0^1 \int_0^{3-3x} (x + y + 1)^{1/2} dy dx = \int_0^1 \left[\frac{2}{3} (x + y + 1)^{3/2} \right]_0^{3-3x} dx \\
 &= \frac{2}{3} \int_0^1 \left[(x + 3 - 3x + 1)^{3/2} - (x + 0 + 1)^{3/2} \right] dx = \frac{2}{3} \int_0^1 \left[(-2x + 4)^{3/2} - (x + 1)^{3/2} \right] dx \\
 &= \frac{2}{3} \left[-\frac{1}{2} \cdot \frac{2}{5} (-2x + 4)^{5/2} - \frac{2}{5} (x + 1)^{5/2} \right]_0^1 = \frac{2}{3} \cdot \frac{2}{5} \left[-\frac{1}{2} (\sqrt{-2x + 4})^5 - (\sqrt{x + 1})^5 \right]_0^1 \\
 &= \frac{4}{15} \left\{ \left[-\frac{1}{2} (\sqrt{2})^5 - (\sqrt{2})^5 \right] - \left[-\frac{1}{2} (\sqrt{4})^5 - (\sqrt{1})^5 \right] \right\} \\
 &= \frac{4}{15} (-2\sqrt{2} - 4\sqrt{2} + 16 + 1) = \frac{4}{15} (17 - 6\sqrt{2}) = \boxed{\frac{4(17 - 6\sqrt{2})}{15}}.
 \end{aligned}$$

9. The part of the surface $z = f(x, y) = 4 - x^2 - y^2$ that lies above the xy plane is shown in the figure below. Its trace in the xy -plane is the disk R given by $x^2 + y^2 \leq 4$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -2x$ and $f_y(x, y) = -2y$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{(-2x)^2 + (-2y)^2 + 1} dA \\
 &= \iint_R \sqrt{4x^2 + 4y^2 + 1} dA = \iint_R \sqrt{4(x^2 + y^2) + 1} dA.
 \end{aligned}$$

Since the region R is a disk and the integrand involves $x^2 + y^2$, we switch to polar coordinates. In polar coordinates, R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$; and we also use the identity $r^2 = x^2 + y^2$ to transform the integrand. Then

$$S = \iint_R \sqrt{4(x^2 + y^2) + 1} dA = \int_0^{2\pi} \int_0^2 \sqrt{4r^2 + 1} \cdot r dr d\theta.$$

To evaluate the “inside” integral $\int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr$, we make a substitution $u = 4r^2 + 1$; then $du = 8r \, dr$, so $r \, dr = \frac{1}{8} du$. We also change the limits of integration: if $r = 0$, then $u = 4 \cdot 0^2 + 1 = 1$; if $r = 2$, then $u = 4 \cdot 2^2 + 1 = 17$. So

$$\int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr = \int_1^{17} \sqrt{u} \cdot \frac{1}{8} du = \frac{1}{8} \int_1^{17} u^{1/2} du = \frac{1}{8} \left[\frac{u^{3/2}}{3/2} \right]_1^{17} = \frac{1}{12} \left[(\sqrt{u})^3 \right]_1^{17} = \frac{17\sqrt{17} - 1}{12}.$$

Going back to the calculation of S ,

$$\begin{aligned} S &= \int_0^{2\pi} \int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta = \int_0^{2\pi} \frac{17\sqrt{17} - 1}{12} d\theta \\ &= \frac{17\sqrt{17} - 1}{12} \cdot [\theta]_0^{2\pi} = \frac{17\sqrt{17} - 1}{12} \cdot (2\pi - 0) = \boxed{\frac{(17\sqrt{17} - 1)\pi}{6}}. \end{aligned}$$

10. The part of the cylinder $z = f(x, y) = \sqrt{a^2 - x^2}$ that lies above the square region R in the xy -plane defined by $-\frac{a}{2} \leq x \leq \frac{a}{2}$, $-\frac{a}{2} \leq y \leq \frac{a}{2}$ is shown in the figure below. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{a^2 - x^2}}$ and $f_y(x, y) = 0$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(-\frac{x}{\sqrt{a^2 - x^2}}\right)^2 + 0^2 + 1} \, dA \\ &= \iint_R \sqrt{\frac{x^2}{a^2 - x^2} + 1} \, dA = \iint_R \sqrt{\frac{a^2}{a^2 - x^2}} \, dA = a \iint_R \frac{1}{\sqrt{a^2 - x^2}} \, dA \\ &= a \int_{-a/2}^{a/2} \int_{-a/2}^{a/2} \frac{1}{\sqrt{a^2 - x^2}} \, dx \, dy = a \int_{-a/2}^{a/2} \left[\sin^{-1} \left(\frac{x}{a} \right) \right]_{-a/2}^{a/2} dy \\ &= a \int_{-a/2}^{a/2} \left[\sin^{-1} \left(\frac{1}{2} \right) - \sin^{-1} \left(-\frac{1}{2} \right) \right] dy = a \int_{-a/2}^{a/2} \left[\frac{\pi}{6} - \left(-\frac{\pi}{6} \right) \right] dy = a \cdot \frac{\pi}{3} \int_{-a/2}^{a/2} dy \\ &= \frac{a\pi}{3} [y]_{-a/2}^{a/2} = \frac{a\pi}{3} \cdot \left[\frac{a}{2} - \left(-\frac{a}{2} \right) \right] = \frac{a\pi}{3} \cdot a = \boxed{\frac{a^2\pi}{3}}. \end{aligned}$$

11. The part of the cone $z = f(x, y) = \sqrt{x^2 + y^2}$ that lies inside the cylinder $x^2 + y^2 = 2x$ is shown in figure (a) below. It lies over the region R in the xy -plane that is the trace of the cylinder in this plane: R is defined by $x^2 + y^2 \leq 2x$ in Cartesian coordinates, and it is a disk of radius 1 centered at the point $(1, 0)$; see figure (b) below. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = \frac{x}{\sqrt{x^2 + y^2}}$ and $f_y(x, y) = \frac{y}{\sqrt{x^2 + y^2}}$. Then the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(\frac{x}{\sqrt{x^2 + y^2}}\right)^2 + \left(\frac{y}{\sqrt{x^2 + y^2}}\right)^2 + 1} \, dA \\
 &= \iint_R \sqrt{\frac{x^2}{x^2 + y^2} + \frac{y^2}{x^2 + y^2} + 1} \, dA = \iint_R \sqrt{2} \, dA = \sqrt{2} \iint_R dA \\
 &= \sqrt{2} \cdot (\text{Area of the disk } R) = \sqrt{2} \cdot (\pi \cdot 1^2) = \boxed{\pi\sqrt{2}}.
 \end{aligned}$$

12. The part of the sphere $x^2 + y^2 + z^2 = 4z$ that lies inside the paraboloid $x^2 + y^2 = 2z$ is shown in the figure below. The equation of the sphere can be rewritten as $x^2 + y^2 + (z - 2)^2 = 4$, so it is a sphere of radius 2 centered at the point $(0, 0, 2)$. The curve of intersection of the sphere and the paraboloid is defined by the system of equations

$$\begin{cases} x^2 + y^2 + z^2 = 4z \\ x^2 + y^2 = 2z \end{cases} \quad \text{or} \quad \begin{cases} x^2 + y^2 = 4z - z^2 \\ x^2 + y^2 = 2z \end{cases}$$

By setting the right-hand sides equal to each other, we find

$$4z - z^2 = 2z, \quad \text{so} \quad 2z - z^2 = 0, \quad \text{so} \quad z(2 - z) = 0, \quad \text{so} \quad z = 0, 2.$$

$z = 0$ is an extraneous solution (the vertex of the paraboloid, which coincides with the lowest point of the sphere). If $z = 2$, then $x^2 + y^2 = 4$, so the curve of intersection is the circle $x^2 + y^2 = 4$, $z = 2$ at the “equator” of the sphere. So the part of the sphere that lies within the paraboloid is the upper hemisphere and its surface area is

$$S = \frac{1}{2} \cdot (\text{Surface area of a sphere of radius } 2) = \frac{1}{2} \cdot (4\pi \cdot 2^2) = \boxed{8\pi}.$$

13. The part of the surface $z = f(x, y) = xy$ that lies in the first octant within the cylinder $x^2 + y^2 = a^2$ ($a > 0$) is shown in figure (a) below. It lies over the region R in the xy -plane that is bounded by the circle $x^2 + y^2 = a^2$ and the coordinate axes in the first quadrant; see figure (b) below. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = y$ and $f_y(x, y) = x$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$S = \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{y^2 + x^2 + 1} \, dA = \iint_R \sqrt{x^2 + y^2 + 1} \, dA.$$

Since the region R is bounded by a part of a circle and the integrand involves $x^2 + y^2$, we switch to polar coordinates. In polar coordinates, R is given by $0 \leq r \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$; and we also use the identity $r^2 = x^2 + y^2$ to transform the integrand. Then

$$S = \iint_R \sqrt{x^2 + y^2 + 1} \, dA = \int_0^{\pi/2} \int_0^a \sqrt{r^2 + 1} \cdot r \, dr \, d\theta.$$

To evaluate the “inside” integral $\int_0^a \sqrt{r^2 + 1} \cdot r \, dr$, we make a substitution $u = r^2 + 1$; then $du = 2r \, dr$, so $r \, dr = \frac{1}{2} du$. We also change the limits of integration: if $r = 0$, then $u = 0^2 + 1 = 1$; if $r = a$, then $u = a^2 + 1$. So

$$\begin{aligned} \int_0^a \sqrt{r^2 + 1} \cdot r \, dr &= \int_1^{a^2+1} \sqrt{u} \cdot \frac{1}{2} \, du = \frac{1}{2} \int_1^{a^2+1} u^{1/2} \, du \\ &= \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_1^{a^2+1} = \frac{1}{3} \left[u^{3/2} \right]_1^{a^2+1} = \frac{(a^2 + 1)^{3/2} - 1}{3}. \end{aligned}$$

Going back to the calculation of S ,

$$\begin{aligned} S &= \int_0^{\pi/2} \int_0^a \sqrt{r^2 + 1} \cdot r \, dr \, d\theta = \int_0^{\pi/2} \frac{(a^2 + 1)^{3/2} - 1}{3} \, d\theta \\ &= \frac{(a^2 + 1)^{3/2} - 1}{3} \cdot [\theta]_0^{\pi/2} = \frac{(a^2 + 1)^{3/2} - 1}{3} \cdot \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi [(a^2 + 1)^{3/2} - 1]}{6}}. \end{aligned}$$

14. The part of the surface $z = f(x, y) = x^2 - y^2$ that lies in the first octant within the cylinder $x^2 + y^2 = 4$ is shown in figure (a) below. It lies over the region R in the xy -plane that is bounded by the circle $x^2 + y^2 = 4$ and the coordinate axes in the first quadrant; see figure (b) below. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = 2x$ and $f_y(x, y) = -2y$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{(2x)^2 + (-2y)^2 + 1} \, dA \\ &= \iint_R \sqrt{4x^2 + 4y^2 + 1} \, dA = \iint_R \sqrt{4(x^2 + y^2) + 1} \, dA. \end{aligned}$$

Since the region R is part of a disk and the integrand involves $x^2 + y^2$, we switch to polar coordinates.

In polar coordinates, R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$; and we also use the identity $r^2 = x^2 + y^2$ to transform the integrand. Then

$$S = \iint_R \sqrt{4(x^2 + y^2) + 1} \, dA = \int_0^{\pi/2} \int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta.$$

To evaluate the “inside” integral $\int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr$, we make a substitution $u = 4r^2 + 1$; then $du = 8r \, dr$, so $r \, dr = \frac{1}{8} du$. We also change the limits of integration: if $r = 0$, then $u = 4 \cdot 0^2 + 1 = 1$; if $r = 2$, then

$u = 4 \cdot 2^2 + 1 = 17$. So

$$\int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr = \int_1^{17} \sqrt{u} \cdot \frac{1}{8} \, du = \frac{1}{8} \int_1^{17} u^{1/2} \, du = \frac{1}{8} \left[\frac{u^{3/2}}{3/2} \right]_1^{17} = \frac{1}{12} \left[(\sqrt{u})^3 \right]_1^{17} = \frac{17\sqrt{17} - 1}{12}.$$

Going back to the calculation of S ,

$$\begin{aligned} S &= \int_0^{\pi/2} \int_0^2 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta = \int_0^{\pi/2} \frac{17\sqrt{17} - 1}{12} \, d\theta \\ &= \frac{17\sqrt{17} - 1}{12} \cdot [\theta]_0^{\pi/2} = \frac{17\sqrt{17} - 1}{12} \cdot \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{(17\sqrt{17} - 1)\pi}{24}}. \end{aligned}$$

15. The part of the sphere $x^2 + y^2 + z^2 = 4z$ that lies between the planes $z = 1$ and $z = 3$ is shown in figure (a) below. The equation of the sphere can be rewritten as $x^2 + y^2 + (z - 2)^2 = 4$, so it is a sphere of radius 2 centered at the point $(0, 0, 2)$. If we substitute either $z = 1$ or $z = 3$ into the equation of the sphere, in both cases we obtain $x^2 + y^2 = 3$, so the curve of intersection of the sphere with either plane is a circle $x^2 + y^2 = 3$ lying in the respective plane. The projection of this part of the sphere onto the xy -plane is the annular region R shown in figure (b) below; in polar coordinates R is given by $\sqrt{3} \leq r \leq 2$, $0 \leq \theta \leq 2\pi$.

Notice that this part of the sphere is symmetric about the sphere's "equator": the part of the surface between $z = 1$ and $z = 2$ is symmetric to the part of the surface between $z = 2$ and $z = 3$; so we can find the surface area of the latter and multiply it by 2. The equation of the upper hemisphere above $z = 2$ can be written as $z = f(x, y) = 2 + \sqrt{4 - x^2 - y^2}$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{4 - x^2 - y^2}}$ and $f_y(x, y) = -\frac{y}{\sqrt{4 - x^2 - y^2}}$. Then the surface area S we seek is

$$\begin{aligned} S &= 2 \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA \\ &= 2 \iint_R \sqrt{\left(-\frac{x}{\sqrt{4 - x^2 - y^2}} \right)^2 + \left(-\frac{y}{\sqrt{4 - x^2 - y^2}} \right)^2 + 1} \, dA \\ &= 2 \iint_R \sqrt{\frac{x^2}{4 - x^2 - y^2} + \frac{y^2}{4 - x^2 - y^2} + 1} \, dA = 2 \iint_R \sqrt{\frac{4}{4 - x^2 - y^2}} \, dA \\ &= 2 \iint_R \frac{2}{\sqrt{4 - x^2 - y^2}} \, dA = 4 \int_0^{2\pi} \int_{\sqrt{3}}^2 \frac{1}{\sqrt{4 - r^2}} \cdot r \, dr \, d\theta = 4 \int_0^{2\pi} \int_{\sqrt{3}}^2 (4 - r^2)^{-1/2} \cdot r \, dr \, d\theta. \end{aligned}$$

To evaluate the "inside" integral $\int_{\sqrt{3}}^2 (4 - r^2)^{-1/2} \cdot r \, dr$, we make a substitution $u = 4 - r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{1}{2} du$. We also change the limits of integration: if $r = \sqrt{3}$, then $u = 4 - (\sqrt{3})^2 = 1$; if $r = 2$, then $u = 4 - 2^2 = 0$. So

$$\begin{aligned} \int_{\sqrt{3}}^2 (4 - r^2)^{-1/2} \cdot r \, dr &= \int_1^0 u^{-1/2} \cdot \left(-\frac{1}{2} du \right) = -\frac{1}{2} \int_1^0 u^{-1/2} \, du \\ &= \frac{1}{2} \int_0^1 u^{-1/2} \, du = \frac{1}{2} \left[\frac{u^{1/2}}{1/2} \right]_0^1 = [\sqrt{u}]_0^1 = 1 - 0 = 1. \end{aligned}$$

Going back to the calculation of S ,

$$S = 4 \int_0^{2\pi} \int_{\sqrt{3}}^2 (4 - r^2)^{-1/2} \cdot r \, dr \, d\theta = 4 \int_0^{2\pi} 1 \, d\theta = 4 [\theta]_0^{2\pi} = 4(2\pi - 0) = \boxed{8\pi}.$$

16. The part of the sphere $x^2 + y^2 + z^2 = 4a^2$ that lies inside the cylinder $x^2 + y^2 = 2ax$ (where $a > 0$) is shown in figure (a) below. Notice that it consists of two symmetric parts in the upper and lower hemispheres; so to find the total required surface area, we can find the surface area of the part lying in the upper hemisphere and multiply it by 2. The projection of this part onto the xy -plane is the disk R bounded by $x^2 + y^2 = 2ax$ that is the trace of the cylinder in this plane. In polar coordinates R is given by $0 \leq r \leq 2a \cos \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; see figure (b) below.

The equation of the upper hemisphere can be written as $z = f(x, y) = \sqrt{4a^2 - x^2 - y^2}$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{4a^2 - x^2 - y^2}}$ and $f_y(x, y) = -\frac{y}{\sqrt{4a^2 - x^2 - y^2}}$. Then the surface area S we seek is

$$\begin{aligned}
 S &= 2 \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA \\
 &= 2 \iint_R \sqrt{\left(-\frac{x}{\sqrt{4a^2 - x^2 - y^2}}\right)^2 + \left(-\frac{y}{\sqrt{4a^2 - x^2 - y^2}}\right)^2 + 1} dA \\
 &= 2 \iint_R \sqrt{\frac{x^2}{4a^2 - x^2 - y^2} + \frac{y^2}{4a^2 - x^2 - y^2} + 1} dA = 2 \iint_R \sqrt{\frac{4a^2}{4a^2 - x^2 - y^2}} dA \\
 &= 2 \iint_R \frac{2a}{\sqrt{4a^2 - x^2 - y^2}} dA = 4a \int_{-\pi/2}^{\pi/2} \int_0^{2a \cos \theta} \frac{1}{\sqrt{4a^2 - r^2}} \cdot r dr d\theta \\
 &= 4a \int_{-\pi/2}^{\pi/2} \int_0^{2a \cos \theta} (4a^2 - r^2)^{-1/2} \cdot r dr d\theta.
 \end{aligned}$$

To evaluate the “inside” integral $\int_0^{2a \cos \theta} (4a^2 - r^2)^{-1/2} \cdot r dr$, we make a substitution $u = 4a^2 - r^2$; then $du = -2r dr$, so $r dr = -\frac{1}{2} du$. We also change the limits of integration: if $r = 0$, then $u = 4a^2 - 0^2 = 4a^2$; if $r = 2a \cos \theta$, then $u = 4a^2 - (2a \cos \theta)^2 = 4a^2 - 4a^2 \cos^2 \theta = 4a^2(1 - \cos^2 \theta) = 4a^2 \sin^2 \theta$. So

$$\begin{aligned}
 \int_0^{2a \cos \theta} (4a^2 - r^2)^{-1/2} \cdot r dr &= \int_{4a^2}^{4a^2 \sin^2 \theta} u^{-1/2} \cdot \left(-\frac{1}{2} du\right) = -\frac{1}{2} \int_{4a^2}^{4a^2 \sin^2 \theta} u^{-1/2} du \\
 &= \frac{1}{2} \int_{4a^2 \sin^2 \theta}^{4a^2} u^{-1/2} du = \frac{1}{2} \left[\frac{u^{1/2}}{1/2} \right]_{4a^2 \sin^2 \theta}^{4a^2} = [\sqrt{u}]_{4a^2 \sin^2 \theta}^{4a^2} \\
 &= \sqrt{4a^2} - \sqrt{4a^2 \sin^2 \theta} = 2a - 2a |\sin \theta| = 2a(1 - |\sin \theta|).
 \end{aligned}$$

Going back to the calculation of S ,

$$S = 4a \int_{-\pi/2}^{\pi/2} \int_0^{2a \cos \theta} (4a^2 - r^2)^{-1/2} \cdot r \, dr \, d\theta = 4a \int_{-\pi/2}^{\pi/2} 2a (1 - |\sin \theta|) \, d\theta = 8a^2 \int_{-\pi/2}^{\pi/2} (1 - |\sin \theta|) \, d\theta.$$

Notice that the integrand $(1 - |\sin \theta|)$ is an even function of θ . So using the property of definite integrals of even functions and the fact that $\sin \theta$ is non-negative when $0 \leq \theta \leq \frac{\pi}{2}$, we can proceed as follows:

$$\begin{aligned} S &= 8a^2 \int_{-\pi/2}^{\pi/2} (1 - |\sin \theta|) \, d\theta = 8a^2 \cdot 2 \int_0^{\pi/2} (1 - |\sin \theta|) \, d\theta = 16a^2 \int_0^{\pi/2} (1 - \sin \theta) \, d\theta \\ &= 16a^2 [\theta + \cos \theta]_0^{\pi/2} = 16a^2 \left[\left(\frac{\pi}{2} + \cos \frac{\pi}{2} \right) - (0 + \cos 0) \right] = 16a^2 \left(\frac{\pi}{2} + 0 - 0 - 1 \right) = \boxed{8a^2(\pi - 2)}. \end{aligned}$$

(b)

Applications and Extensions

17. The part of the surface $y^2 - x^2 = 6z$, or equivalently $z = f(x, y) = \frac{1}{6}(y^2 - x^2)$, that lies within the cylinder $x^2 + y^2 = 36$ is shown in figure (a) below. Its projection onto the xy -plane is the region R that is bounded by the circle $x^2 + y^2 = 36$; see figure (b) below. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{3}$ and $f_y(x, y) = \frac{y}{3}$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(-\frac{x}{3}\right)^2 + \left(\frac{y}{3}\right)^2 + 1} \, dA \\ &= \iint_R \sqrt{\frac{x^2}{9} + \frac{y^2}{9} + 1} \, dA = \iint_R \sqrt{\frac{x^2 + y^2 + 9}{9}} \, dA = \frac{1}{3} \iint_R \sqrt{x^2 + y^2 + 9} \, dA. \end{aligned}$$

Since the region R is a disk and the integrand involves $x^2 + y^2$, we switch to polar coordinates. In polar coordinates, R is given by $0 \leq r \leq 6$, $0 \leq \theta \leq 2\pi$; and we also use the identity $r^2 = x^2 + y^2$ to transform the integrand. Then

$$S = \frac{1}{3} \iint_R \sqrt{x^2 + y^2 + 9} \, dA = \frac{1}{3} \int_0^{2\pi} \int_0^6 \sqrt{r^2 + 9} \cdot r \, dr \, d\theta.$$

To evaluate the “inside” integral $\int_0^6 \sqrt{r^2 + 9} \cdot r \, dr$, we make a substitution $u = r^2 + 9$; then $du = 2r \, dr$, so $r \, dr = \frac{1}{2} du$. We also change the limits of integration: if $r = 0$, then $u = 0^2 + 9 = 9$; if $r = 6$, then

$u = 6^2 + 9 = 45$. So

$$\begin{aligned}\int_0^6 \sqrt{r^2 + 9} \cdot r \, dr &= \int_9^{45} \sqrt{u} \cdot \frac{1}{2} \, du = \frac{1}{2} \int_9^{45} u^{1/2} \, du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_9^{45} \\ &= \frac{1}{3} \left[(\sqrt{u})^3 \right]_9^{45} = \frac{1}{3} \left[(\sqrt{45})^3 - (\sqrt{9})^3 \right] = \frac{1}{3} (135\sqrt{5} - 27) = 45\sqrt{5} - 9.\end{aligned}$$

Going back to the calculation of S ,

$$\begin{aligned}S &= \frac{1}{3} \int_0^{2\pi} \int_0^6 \sqrt{r^2 + 9} \cdot r \, dr \, d\theta = \frac{1}{3} \int_0^{2\pi} (45\sqrt{5} - 9) \, d\theta \\ &= \frac{45\sqrt{5} - 9}{3} \cdot [\theta]_0^{2\pi} = (15\sqrt{5} - 3) \cdot (2\pi - 0) = 3(5\sqrt{5} - 1) \cdot 2\pi = \boxed{6\pi(5\sqrt{5} - 1)}.\end{aligned}$$

(a)

(b)

18. The part of the surface $z = f(x, y) = 4 - y^2$ that lies in the first octant and is enclosed by $z = 0$ (the xy -plane), $x = 0$, $x = y$, and $y = 2$ is shown in figure (a) below. It lies over the region R in the xy -plane that is the triangle enclosed by the lines $x = 0$, $x = y$, and $y = 2$; see figure (b) below. In the xy -plane, R is given by $0 \leq x \leq y$, $0 \leq y \leq 2$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = 0$ and $f_y(x, y) = -2y$. Then the surface area S we seek is

$$\begin{aligned}S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{0^2 + (-2y)^2 + 1} \, dA \\ &= \iint_R \sqrt{4y^2 + 1} \, dA = \int_0^2 \int_0^y \sqrt{4y^2 + 1} \, dx \, dy = \int_0^2 \sqrt{4y^2 + 1} \cdot [x]_0^y \, dy \\ &= \int_0^2 \sqrt{4y^2 + 1} \cdot (y - 0) \, dy = \int_0^2 \sqrt{4y^2 + 1} \cdot y \, dy.\end{aligned}$$

To evaluate this integral, we make a substitution $u = 4y^2 + 1$; then $du = 8y \, dy$, so $y \, dy = \frac{1}{8} du$. We also change the limits of integration: if $y = 0$, then $u = 4 \cdot 0^2 + 1 = 1$; if $y = 2$, then $u = 4 \cdot 2^2 + 1 = 17$. So

$$\int_0^2 \sqrt{4y^2 + 1} \cdot y \, dy = \int_1^{17} \sqrt{u} \cdot \frac{1}{8} \, du = \frac{1}{8} \int_1^{17} u^{1/2} \, du = \frac{1}{8} \left[\frac{u^{3/2}}{3/2} \right]_1^{17} = \frac{1}{12} \left[(\sqrt{u})^3 \right]_1^{17} = \boxed{\frac{17\sqrt{17} - 1}{12}}.$$

19. The part of the surface $x^2 = y$ that lies in the first octant under the plane $x + z = 3$ is shown in figure (a) below. This surface can be interpreted as the graph of a function $y = f(x, z) = x^2$, whose domain is the region R in the xz -plane that is the triangular region enclosed by the line $x + z = 3$ and the coordinate axes; see figure (b) below. In the xz -plane, R is given by $0 \leq z \leq 3 - x$, $0 \leq x \leq 3$. The partial derivatives of $y = f(x, z)$ are $f_x(x, z) = 2x$ and $f_z(x, z) = 0$. Since both f_x and f_z are continuous on R , the surface area S we seek is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, z)]^2 + [f_z(x, z)]^2 + 1} \, dA = \iint_R \sqrt{(2x)^2 + 0^2 + 1} \, dA = \iint_R \sqrt{4x^2 + 1} \, dA \\ &= \int_0^3 \int_0^{3-x} \sqrt{4x^2 + 1} \, dz \, dx = \int_0^3 \sqrt{4x^2 + 1} \cdot [z]_0^{3-x} \, dx = \int_0^3 \sqrt{4x^2 + 1} \cdot [(3-x) - 0] \, dx \\ &= \int_0^3 \sqrt{4x^2 + 1} \cdot (3-x) \, dx = 3 \int_0^3 \sqrt{4x^2 + 1} \, dx - \int_0^3 \sqrt{4x^2 + 1} \cdot x \, dx. \end{aligned}$$

To evaluate the second integral, we make a substitution $u = 4x^2 + 1$; then $du = 8x \, dx$, so $x \, dx = \frac{1}{8} du$. We also change the limits of integration: if $x = 0$, then $u = 4 \cdot 0^2 + 1 = 1$; if $x = 3$, then $u = 4 \cdot 3^2 + 1 = 37$. So

$$\int_0^3 \sqrt{4x^2 + 1} \cdot x \, dx = \int_1^{37} \sqrt{u} \cdot \frac{1}{8} \, du = \frac{1}{8} \int_1^{37} u^{1/2} \, du = \frac{1}{8} \left[\frac{u^{3/2}}{3/2} \right]_1^{37} = \frac{1}{12} \left[(\sqrt{u})^3 \right]_1^{37} = \frac{37\sqrt{37} - 1}{12}.$$

To find the first integral, we will find an antiderivative using a substitution $2x = \tan \theta$, $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$; then $x = \frac{1}{2} \tan \theta$ and $dx = \frac{1}{2} \sec^2 \theta \, d\theta$. Also,

$$\sqrt{4x^2 + 1} = \sqrt{4 \cdot \frac{1}{4} \tan^2 \theta + 1} = \sqrt{\tan^2 \theta + 1} = \sqrt{\sec^2 \theta} = \sec \theta,$$

and the integral becomes

$$3 \int \sqrt{4x^2 + 1} \, dx = 3 \int \sec \theta \cdot \frac{1}{2} \sec^2 \theta \, d\theta = \frac{3}{2} \int \sec^3 \theta \, d\theta.$$

To find the integral $\int \sec^3 \theta \, d\theta$, we use the method of integration by parts. If we choose $u = \sec \theta$ and $dv = \sec^2 \theta \, d\theta$, then $du = \sec \theta \tan \theta \, d\theta$ and $v = \int \sec^2 \theta \, d\theta = \tan \theta$. So

$$\begin{aligned} \int \sec^3 \theta \, d\theta &= \sec \theta \cdot \tan \theta - \int \tan \theta \cdot \sec \theta \tan \theta \, d\theta = \sec \theta \tan \theta - \int \sec \theta \tan^2 \theta \, d\theta \\ &= \sec \theta \tan \theta - \int \sec \theta (\sec^2 \theta - 1) \, d\theta = \sec \theta \tan \theta - \int \sec^3 \theta \, d\theta + \int \sec \theta \, d\theta \\ &= \sec \theta \tan \theta + \ln |\sec \theta + \tan \theta| - \int \sec^3 \theta \, d\theta. \end{aligned}$$

So we obtained an equation

$$\int \sec^3 \theta \, d\theta = \sec \theta \tan \theta + \ln |\sec \theta + \tan \theta| - \int \sec^3 \theta \, d\theta,$$

from which we find that

$$\begin{aligned} 2 \int \sec^3 \theta \, d\theta &= \sec \theta \tan \theta + \ln |\sec \theta + \tan \theta|, \\ \int \sec^3 \theta \, d\theta &= \frac{1}{2} (\sec \theta \tan \theta + \ln |\sec \theta + \tan \theta|), \\ \frac{3}{2} \int \sec^3 \theta \, d\theta &= \frac{3}{4} (\sec \theta \tan \theta + \ln |\sec \theta + \tan \theta|). \end{aligned}$$

To express this antiderivative in terms of x , recall that we substituted $2x = \tan \theta$ and $\sqrt{4x^2 + 1} = \sec \theta$. So an antiderivative is

$$\begin{aligned} 3 \int \sqrt{4x^2 + 1} \, dx &= \frac{3}{2} \int \sec^3 \theta \, d\theta = \frac{3}{4} (\sec \theta \tan \theta + \ln |\sec \theta + \tan \theta|) \\ &= \frac{3}{4} (\sqrt{4x^2 + 1} \cdot 2x + \ln |\sqrt{4x^2 + 1} + 2x|) \\ &= \frac{3}{4} (2x\sqrt{4x^2 + 1} + \ln |\sqrt{4x^2 + 1} + 2x|), \end{aligned}$$

and the value of the first integral is

$$\begin{aligned} 3 \int_0^3 \sqrt{4x^2 + 1} \, dx &= \frac{3}{4} \left[(2x\sqrt{4x^2 + 1} + \ln |\sqrt{4x^2 + 1} + 2x|) \right]_0^3 \\ &= \frac{3}{4} (6\sqrt{37} + \ln |\sqrt{37} + 6|) - \frac{3}{4} (0\sqrt{1} + \ln |\sqrt{1} + 0|) \\ &= \frac{3}{4} [6\sqrt{37} + \ln (\sqrt{37} + 6)] - \frac{3}{4} (0 + \ln 1) = \frac{18\sqrt{37} + 3 \ln (\sqrt{37} + 6)}{4}. \end{aligned}$$

Going back to the calculation of the surface area,

$$\begin{aligned} S &= 3 \int_0^3 \sqrt{4x^2 + 1} \, dx - \int_0^3 \sqrt{4x^2 + 1} \cdot x \, dx = \frac{18\sqrt{37} + 3 \ln (\sqrt{37} + 6)}{4} - \frac{37\sqrt{37} - 1}{12} \\ &= \frac{[54\sqrt{37} + 9 \ln (\sqrt{37} + 6)] - (37\sqrt{37} - 1)}{12} = \boxed{\frac{1 + 17\sqrt{37} + 9 \ln (\sqrt{37} + 6)}{12}}. \end{aligned}$$

(a)

(b)

20. The part of the paraboloid $z = 9 - x^2 - y^2$ that lies between the planes $z = 0$ and $z = 8$ is shown in figure (a) below. If we substitute $z = 0$ into the equation of the paraboloid, we obtain $0 = 9 - x^2 - y^2$ or $x^2 + y^2 = 9$; if we substitute $z = 8$ into the equation of the paraboloid, we obtain $8 = 9 - x^2 - y^2$ or $x^2 + y^2 = 1$. So the projection of this part of the paraboloid onto the xy -plane is the annular region R shown in figure (b) below; in polar coordinates R is given by $1 \leq r \leq 3$, $0 \leq \theta \leq 2\pi$.

The partial derivatives of $z = f(x, y) = 9 - x^2 - y^2$ are $f_x(x, y) = -2x$ and $f_y(x, y) = -2y$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{(-2x)^2 + (-2y)^2 + 1} \, dA \\ &= \iint_R \sqrt{4x^2 + 4y^2 + 1} \, dA = \iint_R \sqrt{4(x^2 + y^2) + 1} \, dA = \int_0^{2\pi} \int_1^3 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta. \end{aligned}$$

To evaluate the “inside” integral $\int_1^3 \sqrt{4r^2 + 1} \cdot r \, dr$, we make a substitution $u = 4r^2 + 1$; then $du = 8r \, dr$, so $r \, dr = \frac{1}{8} du$. We also change the limits of integration: if $r = 1$, then $u = 4 \cdot 1^2 + 1 = 5$; if $r = 3$, then $u = 4 \cdot 3^2 + 1 = 37$. So

$$\int_1^3 \sqrt{4r^2 + 1} \cdot r \, dr = \int_5^{37} \sqrt{u} \cdot \frac{1}{8} du = \frac{1}{8} \int_5^{37} u^{1/2} du = \frac{1}{8} \left[\frac{u^{3/2}}{3/2} \right]_5^{37} = \frac{1}{12} \left[(\sqrt{u})^3 \right]_5^{37} = \frac{37\sqrt{37} - 5\sqrt{5}}{12}.$$

Going back to the calculation of S ,

$$\begin{aligned} S &= \int_0^{2\pi} \int_1^3 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta = \int_0^{2\pi} \frac{37\sqrt{37} - 5\sqrt{5}}{12} d\theta \\ &= \frac{37\sqrt{37} - 5\sqrt{5}}{12} \cdot [\theta]_0^{2\pi} = \frac{37\sqrt{37} - 5\sqrt{5}}{12} \cdot (2\pi - 0) = \boxed{\frac{(37\sqrt{37} - 5\sqrt{5})\pi}{6}}. \end{aligned}$$

21. The part of the hemisphere $x^2 + y^2 + z^2 = 16$, $z \geq 0$ that lies inside the cylinder $x^2 + y^2 = 4$ is shown in the figure in Problem 21. The equation of the hemisphere can be rewritten as $z = f(x, y) = \sqrt{16 - x^2 - y^2}$. The projection of this part of the hemisphere onto the xy -plane is the region R that is a disk in the xy -plane bounded by the circle $x^2 + y^2 = 4$ (the base of the cylinder, as shown in the same figure). In polar coordinates R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$.

The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{16 - x^2 - y^2}}$ and $f_y(x, y) = -\frac{y}{\sqrt{16 - x^2 - y^2}}$.

Then the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA \\
 &= \iint_R \sqrt{\left(-\frac{x}{\sqrt{16-x^2-y^2}}\right)^2 + \left(-\frac{y}{\sqrt{16-x^2-y^2}}\right)^2 + 1} \, dA \\
 &= \iint_R \sqrt{\frac{x^2}{16-x^2-y^2} + \frac{y^2}{16-x^2-y^2} + 1} \, dA = \iint_R \sqrt{\frac{16}{16-x^2-y^2}} \, dA \\
 &= \iint_R \frac{4}{\sqrt{16-x^2-y^2}} \, dA = 4 \int_0^{2\pi} \int_0^2 \frac{1}{\sqrt{16-r^2}} \cdot r \, dr \, d\theta = 4 \int_0^{2\pi} \int_0^2 (16-r^2)^{-1/2} \cdot r \, dr \, d\theta.
 \end{aligned}$$

To evaluate the “inside” integral $\int_0^2 (16-r^2)^{-1/2} \cdot r \, dr$, we make a substitution $u = 16-r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{1}{2} du$. We also change the limits of integration: if $r = 0$, then $u = 16-0^2 = 16$; if $r = 2$, then $u = 16-2^2 = 12$. So

$$\begin{aligned}
 \int_0^2 (16-r^2)^{-1/2} \cdot r \, dr &= \int_{16}^{12} u^{-1/2} \cdot \left(-\frac{1}{2} du\right) = -\frac{1}{2} \int_{16}^{12} u^{-1/2} \, du = \frac{1}{2} \int_{12}^{16} u^{-1/2} \, du \\
 &= \frac{1}{2} \left[\frac{u^{1/2}}{1/2} \right]_{12}^{16} = [\sqrt{u}]_{12}^{16} = \sqrt{16} - \sqrt{12} = 4 - 2\sqrt{3} = 2(2 - \sqrt{3}).
 \end{aligned}$$

Going back to the calculation of S ,

$$\begin{aligned}
 S &= 4 \int_0^{2\pi} \int_0^2 (16-r^2)^{-1/2} \cdot r \, dr \, d\theta = 4 \int_0^{2\pi} 2(2 - \sqrt{3}) \, d\theta \\
 &= 4 \cdot 2(2 - \sqrt{3}) \cdot [\theta]_0^{2\pi} = 8(2 - \sqrt{3}) \cdot (2\pi - 0) = \boxed{16\pi(2 - \sqrt{3})}.
 \end{aligned}$$

22. Let's introduce a rectangular coordinate system such that its xy -plane is the floor of the Pantheon, the origin is at the circular floor's center, and the z -axis goes vertically up. Then the inner surface of the Pantheon, which is a hemisphere of diameter 43.3 m, or equivalently or radius 21.65 m, can be represented by the equation $x^2 + y^2 + z^2 = 21.65^2$, $z \geq 0$, or $z = f(x, y) = \sqrt{21.65^2 - x^2 - y^2}$. The open circular ocular cut from its apex (see the figure in Problem 22) has a diameter of 9.1 m, or equivalently a radius of 4.55 m. The projection of this opening onto the xy -plane is the interior of the circle $x^2 + y^2 = 4.55^2$. A geometrical representation of the inner surface of the Pantheon is shown in figure (a) below. The projection of this surface onto the xy -plane is the annular region R shown in figure (b) below; in polar coordinates R is given by $4.55 \leq r \leq 21.65$, $0 \leq \theta \leq 2\pi$.

The partial derivatives of $z = f(x, y)$ are

$$f_x(x, y) = -\frac{x}{\sqrt{21.65^2 - x^2 - y^2}} \quad \text{and} \quad f_y(x, y) = -\frac{y}{\sqrt{21.65^2 - x^2 - y^2}}.$$

Then the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA \\
 &= \iint_R \sqrt{\left(-\frac{x}{\sqrt{21.65^2 - x^2 - y^2}}\right)^2 + \left(-\frac{y}{\sqrt{21.65^2 - x^2 - y^2}}\right)^2 + 1} dA \\
 &= \iint_R \sqrt{\frac{x^2}{21.65^2 - x^2 - y^2} + \frac{y^2}{21.65^2 - x^2 - y^2} + 1} dA = \iint_R \sqrt{\frac{21.65^2}{21.65^2 - x^2 - y^2}} dA \\
 &= \iint_R \frac{21.65}{\sqrt{21.65^2 - x^2 - y^2}} dA = 21.65 \int_0^{2\pi} \int_{4.55}^{21.65} \frac{1}{\sqrt{21.65^2 - r^2}} \cdot r dr d\theta \\
 &= 21.65 \int_0^{2\pi} \int_{4.55}^{21.65} (21.65^2 - r^2)^{-1/2} \cdot r dr d\theta.
 \end{aligned}$$

To evaluate the “inside” integral $\int_{4.55}^{21.65} (21.65^2 - r^2)^{-1/2} \cdot r dr$, we make a substitution $u = 21.65^2 - r^2$; then $du = -2r dr$, so $r dr = -\frac{1}{2} du$. We also change the limits of integration: if $r = 4.55$, then $u = 21.65^2 - 4.55^2 = 448.02$; if $r = 21.65$, then $u = 21.65^2 - 21.65^2 = 0$. So

$$\begin{aligned}
 \int_{4.55}^{21.65} (21.65^2 - r^2)^{-1/2} \cdot r dr &= \int_{448.02}^0 u^{-1/2} \cdot \left(-\frac{1}{2} du\right) = -\frac{1}{2} \int_{448.02}^0 u^{-1/2} du \\
 &= \frac{1}{2} \int_0^{448.02} u^{-1/2} du = \frac{1}{2} \left[\frac{u^{1/2}}{1/2} \right]_0^{448.02} = [\sqrt{u}]_0^{448.02} \\
 &= \sqrt{448.02} - \sqrt{0} = \sqrt{448.02}.
 \end{aligned}$$

Going back to the calculation of S ,

$$\begin{aligned}
 S &= 21.65 \int_0^{2\pi} \int_{4.55}^{21.65} (21.65^2 - r^2)^{-1/2} \cdot r dr d\theta = 21.65 \int_0^{2\pi} \sqrt{448.02} d\theta \\
 &= 21.65 \cdot \sqrt{448.02} \cdot [\theta]_0^{2\pi} = 21.65 \sqrt{448.02} \cdot (2\pi - 0) = \boxed{43.3 \sqrt{448.02} \pi \approx 2879.297 \text{ m}^2}.
 \end{aligned}$$

23. (a) Using the computer algebra system *Mathematica*, we can obtain a graph of the part of the surface $z = f(x, y) = 10e^{-(x^2+y^2)}$ that lies inside the cylinder $x^2 + y^2 = 4$ as shown in figure (a) below.

- (b) The projection of this surface onto the xy -plane is the region R that is the disk bounded by the circle $x^2 + y^2 = 4$; see figure (b) below. In polar coordinates R is given by $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -20xe^{-(x^2+y^2)}$ and $f_y(x, y) = -20ye^{-(x^2+y^2)}$. Then the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA \\
 &= \iint_R \sqrt{(-20xe^{-(x^2+y^2)})^2 + (-20ye^{-(x^2+y^2)})^2 + 1} \, dA \\
 &= \iint_R \sqrt{400x^2e^{-2(x^2+y^2)} + 400y^2e^{-2(x^2+y^2)} + 1} \, dA \\
 &= \iint_R \sqrt{400(x^2 + y^2)e^{-2(x^2+y^2)} + 1} \, dA \\
 &= \int_0^{2\pi} \int_0^2 \sqrt{400r^2e^{-2r^2} + 1} \cdot r \, dr \, d\theta.
 \end{aligned}$$

Entering this double integral into *Mathematica*, we find that its value is approximately

$$S = \int_0^{2\pi} \int_0^2 \sqrt{400r^2e^{-2r^2} + 1} \cdot r \, dr \, d\theta \approx \boxed{55.436}.$$

(a)

(b)

24. (a) If we substitute $z = 0$ into the equation of the surface $z = 1 - x^4 - y^2$, we obtain $0 = 1 - x^4 - y^2$ or $x^4 + y^2 = 1$. So the projection of the part of this surface that lies above the xy -plane onto the xy -plane is the region R enclosed by the graph of $x^4 + y^2 = 1$, as shown in figure (a) below. The partial derivatives of $z = f(x, y) = 1 - x^4 - y^2$ are $f_x(x, y) = -4x^3$ and $f_y(x, y) = -2y$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA \\
 &= \iint_R \sqrt{(-4x^3)^2 + (-2y)^2 + 1} \, dA = \boxed{\iint_R \sqrt{16x^6 + 4y^2 + 1} \, dA}.
 \end{aligned}$$

- (b) Using the computer algebra system *Mathematica*, we can generate the graph of the part of the surface $z = 1 - x^4 - y^2$ that lies above the xy -plane as shown in figure (b) below.

25. If we place a right circular cone of base radius a and altitude h in the rectangular coordinate system “upside down” with its vertex at the origin and its axis of symmetry up along the z -axis, as shown in figure (a) below, then this cone is given by the equation $\frac{z^2}{h^2} = \frac{x^2}{a^2} + \frac{y^2}{a^2}$, $0 \leq z \leq h$. This equation can be rewritten as $z = f(x, y) = \frac{h}{a} \sqrt{x^2 + y^2}$, $0 \leq z \leq h$. Its projection onto the xy -plane is the region R that is a disk bounded by the circle $x^2 + y^2 = a^2$, as shown in figure (b) below.

The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = \frac{hx}{a\sqrt{x^2 + y^2}}$ and $f_y(x, y) = \frac{hy}{a\sqrt{x^2 + y^2}}$. Then the lateral surface area S of this cone is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(\frac{hx}{a\sqrt{x^2 + y^2}}\right)^2 + \left(\frac{hy}{a\sqrt{x^2 + y^2}}\right)^2 + 1} \, dA \\
 &= \iint_R \sqrt{\frac{h^2 x^2}{a^2(x^2 + y^2)} + \frac{h^2 y^2}{a^2(x^2 + y^2)} + 1} \, dA = \iint_R \sqrt{\frac{h^2(x^2 + y^2)}{a^2(x^2 + y^2)} + 1} \, dA \\
 &= \iint_R \sqrt{\frac{h^2}{a^2} + 1} \, dA = \sqrt{\frac{h^2}{a^2} + 1} \iint_R dA = \sqrt{\frac{h^2 + a^2}{a^2}} \iint_R dA = \frac{1}{a} \sqrt{h^2 + a^2} \iint_R dA \\
 &= \frac{1}{a} \sqrt{a^2 + h^2} \cdot (\text{area of } R) = \frac{1}{a} \sqrt{a^2 + h^2} \cdot \pi a^2 = \pi a \sqrt{a^2 + h^2},
 \end{aligned}$$

as desired.

26. The first-octant portion of the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ (where a , b , and c are positive) is shown in

figure (a) below. This equation can be rewritten as $z = f(x, y) = c \left(1 - \frac{x}{a} - \frac{y}{b}\right)$. If substitute $z = 0$ into the equation of the plane, we obtain $\frac{x}{a} + \frac{y}{b} = 1$. So the projection of this part of the plane onto the xy -plane is the triangular region R in the xy -plane bounded by the coordinate axes and the line $\frac{x}{a} + \frac{y}{b} = 1$; see figure (b) below.

The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{c}{a}$ and $f_y(x, y) = -\frac{c}{b}$. Since both f_x and f_y are continuous on R , the surface area S we seek is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(-\frac{c}{a}\right)^2 + \left(-\frac{c}{b}\right)^2 + 1} \, dA \\
 &= \iint_R \sqrt{\frac{c^2}{a^2} + \frac{c^2}{b^2} + 1} \, dA = \iint_R \sqrt{\frac{c^2 b^2}{a^2 b^2} + \frac{c^2 a^2}{a^2 b^2} + \frac{a^2 b^2}{a^2 b^2}} \, dA = \iint_R \sqrt{\frac{c^2 b^2 + c^2 a^2 + a^2 b^2}{a^2 b^2}} \, dA \\
 &= \sqrt{\frac{c^2 b^2 + c^2 a^2 + a^2 b^2}{a^2 b^2}} \iint_R dA = \frac{\sqrt{a^2 b^2 + b^2 c^2 + c^2 a^2}}{ab} \iint_R dA \\
 &= \frac{\sqrt{a^2 b^2 + b^2 c^2 + c^2 a^2}}{ab} \cdot (\text{area of } R) = \frac{\sqrt{a^2 b^2 + b^2 c^2 + c^2 a^2}}{ab} \cdot \frac{1}{2} ab = \frac{1}{2} \sqrt{a^2 b^2 + b^2 c^2 + c^2 a^2},
 \end{aligned}$$

as desired.

(a)

(b)

27. If we place the sphere of radius R in the rectangular coordinate system so that its center is at the origin, then the equation of the sphere is $x^2 + y^2 + z^2 = R^2$; see figure (a) below. Since the sphere is symmetric about the xy -plane, we can find the surface area of the upper hemisphere $x^2 + y^2 + z^2 = R^2$, $z \geq 0$ and multiply it by 2.

The equation of the upper hemisphere can be rewritten as $z = f(x, y) = \sqrt{R^2 - x^2 - y^2}$. If we substitute $z = 0$ into the equation of the sphere, we obtain $x^2 + y^2 = R^2$, so the projection of the sphere onto the xy -plane is the region T that is a disk in the xy -plane bounded by the circle $x^2 + y^2 = R^2$; see figure (b) below. In polar coordinates T is given by $0 \leq r \leq R$, $0 \leq \theta \leq 2\pi$.

The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{R^2 - x^2 - y^2}}$ and $f_y(x, y) = -\frac{y}{\sqrt{R^2 - x^2 - y^2}}$.

So the surface area S we seek is

$$\begin{aligned}
 S &= 2 \iint_T \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA \\
 &= 2 \iint_T \sqrt{\left(-\frac{x}{\sqrt{R^2 - x^2 - y^2}}\right)^2 + \left(-\frac{y}{\sqrt{R^2 - x^2 - y^2}}\right)^2 + 1} \, dA \\
 &= 2 \iint_T \sqrt{\frac{x^2}{R^2 - x^2 - y^2} + \frac{y^2}{R^2 - x^2 - y^2} + 1} \, dA = 2 \iint_T \sqrt{\frac{R^2}{R^2 - x^2 - y^2}} \, dA \\
 &= 2 \iint_T \frac{R}{\sqrt{R^2 - x^2 - y^2}} \, dA = 2R \int_0^{2\pi} \int_0^R \frac{1}{\sqrt{R^2 - r^2}} \cdot r \, dr \, d\theta \\
 &= 2R \int_0^{2\pi} \int_0^R (R^2 - r^2)^{-1/2} \cdot r \, dr \, d\theta.
 \end{aligned}$$

To evaluate the “inside” integral $\int_0^R (R^2 - r^2)^{-1/2} \cdot r \, dr$, we make a substitution $u = R^2 - r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{1}{2} du$. We also change the limits of integration: if $r = 0$, then $u = R^2 - 0^2 = R^2$; if $r = R$, then $u = R^2 - R^2 = 0$. So

$$\begin{aligned}
 \int_0^R (R^2 - r^2)^{-1/2} \cdot r \, dr &= \int_{R^2}^0 u^{-1/2} \cdot \left(-\frac{1}{2} du\right) = -\frac{1}{2} \int_{R^2}^0 u^{-1/2} du \\
 &= \frac{1}{2} \int_0^{R^2} u^{-1/2} du = \frac{1}{2} \left[\frac{u^{1/2}}{1/2} \right]_0^{R^2} = [\sqrt{u}]_0^{R^2} = \sqrt{R^2} - \sqrt{0} = R - 0 = R.
 \end{aligned}$$

Going back to the calculation of S ,

$$S = 2R \int_0^{2\pi} \int_0^R (R^2 - r^2)^{-1/2} \cdot r \, dr \, d\theta = 2R \int_0^{2\pi} R \, d\theta = 2R \cdot R \cdot [\theta]_0^{2\pi} = 2R^2 \cdot (2\pi - 0) = 4\pi R^2,$$

which is precisely the well-known formula for the surface area of a sphere.

Challenge Problems

28. Since it is given that $F_z(x, y, z) \neq 0$ at all points of the domain, we can apply the Implicit Differentiation Formulas II (Section 12.5, pg. 855): the equation $F(x, y, z) = 0$ defines $z = f(x, y)$ as an implicit function of x and y , and its partial derivatives are

$$\frac{\partial z}{\partial x} = -\frac{F_x(x, y, z)}{F_z(x, y, z)} \quad \text{and} \quad \frac{\partial z}{\partial y} = -\frac{F_y(x, y, z)}{F_z(x, y, z)}.$$

Then the area S of the part of the surface $F(x, y, z) = 0$ that lies over a closed bounded region R is

$$\begin{aligned}
 S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{\left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2 + 1} dA \\
 &= \iint_R \sqrt{\left[-\frac{F_x(x, y, z)}{F_z(x, y, z)}\right]^2 + \left[-\frac{F_y(x, y, z)}{F_z(x, y, z)}\right]^2 + 1} dA \\
 &= \iint_R \sqrt{\frac{[F_x(x, y, z)]^2}{[F_z(x, y, z)]^2} + \frac{[F_y(x, y, z)]^2}{[F_z(x, y, z)]^2} + 1} dA \\
 &= \iint_R \sqrt{\frac{[F_x(x, y, z)]^2}{[F_z(x, y, z)]^2} + \frac{[F_y(x, y, z)]^2}{[F_z(x, y, z)]^2} + \frac{[F_z(x, y, z)]^2}{[F_z(x, y, z)]^2}} dA \\
 &= \iint_R \sqrt{\frac{[F_x(x, y, z)]^2 + [F_y(x, y, z)]^2 + [F_z(x, y, z)]^2}{[F_z(x, y, z)]^2}} dA \\
 &= \iint_R \frac{\sqrt{[F_x(x, y, z)]^2 + [F_y(x, y, z)]^2 + [F_z(x, y, z)]^2}}{|F_z(x, y, z)|} dA,
 \end{aligned}$$

as desired.

29. Consider the sphere, the cylinder, and the surface that is cut from the sphere by the cylinder, as shown in the figure in Problem 29. If we shift the entire configuration to the left along the y -axis by $\frac{R}{2}$ units, so that the center of the sphere moves to the origin, then the area of the surface does not change; see figure (a) below. Now the sphere with its center at the origin and radius of R can be described by the equation $x^2 + y^2 + z^2 = R^2$. The cylinder after the shift contains the z -axis, and its trace in the xy -plane is the circle of radius $\frac{R}{2}$ centered at the point $\left(0, -\frac{R}{2}, 0\right)$. In Cartesian coordinates, the equation of the cylinder, as well as of its trace in the xy -plane, is $x^2 + \left(y + \frac{R}{2}\right)^2 = \frac{R^2}{4}$. This trace, which is a circle, encloses a region Ω in the xy -plane, that in polar coordinates can be described by $0 \leq r \leq -R \sin \theta$, where $\pi \leq \theta \leq 2\pi$; see figure (b) below.

Notice that the part of the sphere that lies inside the cylinder consists of two symmetric parts in the upper and lower hemispheres; moreover, either half of the surface is also symmetric about the yz -plane, and the region Ω is symmetric about the y -axis. So to find the total required surface area, we can find the surface area of the part lying in the upper hemisphere above the fourth-quadrant

half of Ω and multiply that by 4. The equation of the upper hemisphere can be written as $z = f(x, y) = \sqrt{R^2 - x^2 - y^2}$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{x}{\sqrt{R^2 - x^2 - y^2}}$ and $f_y(x, y) = -\frac{y}{\sqrt{R^2 - x^2 - y^2}}$. The region Ω' , that is the fourth-quadrant half of Ω , is defined by limiting the values of the polar angle to $\frac{3\pi}{2} \leq \theta \leq 2\pi$. Then the surface area S we seek is

$$\begin{aligned}
 S &= 4 \iint_{\Omega'} \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA \\
 &= 4 \iint_{\Omega'} \sqrt{\left(-\frac{x}{\sqrt{R^2 - x^2 - y^2}}\right)^2 + \left(-\frac{y}{\sqrt{R^2 - x^2 - y^2}}\right)^2 + 1} \, dA \\
 &= 4 \iint_{\Omega'} \sqrt{\frac{x^2}{R^2 - x^2 - y^2} + \frac{y^2}{R^2 - x^2 - y^2} + 1} \, dA = 4 \iint_{\Omega'} \sqrt{\frac{R^2}{R^2 - x^2 - y^2}} \, dA \\
 &= 4 \iint_{\Omega'} \frac{R}{\sqrt{R^2 - x^2 - y^2}} \, dA = 4R \int_{3\pi/2}^{2\pi} \int_0^{-R \sin \theta} \frac{1}{\sqrt{R^2 - r^2}} \cdot r \, dr \, d\theta \\
 &= 4R \int_{3\pi/2}^{2\pi} \int_0^{-R \sin \theta} (R^2 - r^2)^{-1/2} \cdot r \, dr \, d\theta.
 \end{aligned}$$

To evaluate the “inside” integral $\int_0^{-R \sin \theta} (R^2 - r^2)^{-1/2} \cdot r \, dr$, we make a substitution $u = R^2 - r^2$; then $du = -2r \, dr$, so $r \, dr = -\frac{1}{2} du$. We also change the limits of integration: if $r = 0$, then $u = R^2 - 0^2 = R^2$; if $r = -R \sin \theta$, then $u = R^2 - (-R \sin \theta)^2 = R^2 - R^2 \sin^2 \theta = R^2(1 - \sin^2 \theta) = R^2 \cos^2 \theta$. So

$$\begin{aligned}
 \int_0^{-R \sin \theta} (R^2 - r^2)^{-1/2} \cdot r \, dr &= \int_{R^2}^{R^2 \cos^2 \theta} u^{-1/2} \cdot \left(-\frac{1}{2} du\right) = -\frac{1}{2} \int_{R^2}^{R^2 \cos^2 \theta} u^{-1/2} \, du \\
 &= \frac{1}{2} \int_{R^2 \cos^2 \theta}^{R^2} u^{-1/2} \, du = \frac{1}{2} \left[\frac{u^{1/2}}{1/2} \right]_{R^2 \cos^2 \theta}^{R^2} = [\sqrt{u}]_{R^2 \cos^2 \theta}^{R^2} \\
 &= \sqrt{R^2} - \sqrt{R^2 \cos^2 \theta} = R - R \cos \theta = R(1 - \cos \theta),
 \end{aligned}$$

where we used the fact that $\cos \theta \geq 0$ because $\frac{3\pi}{2} \leq \theta \leq 2\pi$. Going back to the calculation of S ,

$$\begin{aligned}
 S &= 4R \int_{3\pi/2}^{2\pi} \int_0^{-R \sin \theta} (R^2 - r^2)^{-1/2} \cdot r \, dr \, d\theta = 4R \int_{3\pi/2}^{2\pi} R(1 - \cos \theta) \, d\theta \\
 &= 4R^2 \int_{3\pi/2}^{2\pi} (1 - \cos \theta) \, d\theta = 4R^2 [\theta - \sin \theta]_{3\pi/2}^{2\pi} = 4R^2 \left[(2\pi - \sin(2\pi)) - \left(\frac{3\pi}{2} - \sin \frac{3\pi}{2} \right) \right] \\
 &= 4R^2 \left[(2\pi - 0) - \left(\frac{3\pi}{2} - (-1) \right) \right] = 4R^2 \left(\frac{\pi}{2} - 1 \right) = \boxed{2R^2(\pi - 2) \text{ square units}}.
 \end{aligned}$$

30. To find the positive non-obtuse angle θ between two vectors $\mathbf{v}_1$ and $\mathbf{v}_2$, we can use the formula $\cos \theta = \frac{|\mathbf{v}_1 \cdot \mathbf{v}_2|}{\|\mathbf{v}_1\| \|\mathbf{v}_2\|}$, where $0 \leq \theta \leq \frac{\pi}{2}$ (see the discussion for Problems 71-76 in Section 10.6, pg. 742).

In particular, if γ is the positive acute angle between the normal vector $\mathbf{n} = A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$, where $C \neq 0$, and the unit vector $\mathbf{k}$, then

$$\cos \gamma = \frac{|\mathbf{n} \cdot \mathbf{k}|}{\|\mathbf{n}\| \|\mathbf{k}\|} = \frac{|(A\mathbf{i} + B\mathbf{j} + C\mathbf{k}) \cdot \mathbf{k}|}{\sqrt{A^2 + B^2 + C^2} \cdot 1} = \frac{|C|}{\sqrt{A^2 + B^2 + C^2}},$$

$$\text{so } \sec \gamma = \frac{1}{\cos \gamma} = \frac{\sqrt{A^2 + B^2 + C^2}}{|C|}.$$

Now, consider the plane surface given by the equation $F(x, y, z) = Ax + By + Cz - D = 0$, where $C \neq 0$. The normal vector to this plane is precisely the vector $\mathbf{n} = A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$ considered above.

The equation of the plane can be rewritten as $z = f(x, y) = \frac{D - Ax - By}{C}$. The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{A}{C}$ and $f_y(x, y) = -\frac{B}{C}$. So the surface area S of the part of the plane lying above a closed bounded region R in the xy -plane is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{\left(-\frac{A}{C}\right)^2 + \left(-\frac{B}{C}\right)^2 + 1} \, dA \\ &= \iint_R \sqrt{\frac{A^2}{C^2} + \frac{B^2}{C^2} + 1} \, dA = \iint_R \sqrt{\frac{A^2}{C^2} + \frac{B^2}{C^2} + \frac{C^2}{C^2}} \, dA \\ &= \iint_R \sqrt{\frac{A^2 + B^2 + C^2}{C^2}} \, dA = \iint_R \frac{\sqrt{A^2 + B^2 + C^2}}{|C|} \, dA = \iint_R \sec \gamma \, dA, \end{aligned}$$

as desired.

14.6 The Triple Integral

Concepts and Vocabulary

1. True by the statement of an xy -simple solid in subsection 2.
2. False. The projection of an xy -simple solid onto the xy -plane is a closed, bounded region R , but this region R does not have to be bounded by smooth curves.
3. True by the statement of the mass M of a solid E of volume V with mass density $\rho = \rho(x, y, z)$ from subsection 4.
4. False. The triple integral of $\iiint_E dV$ represents the volume of the solid E .

Skill Building

5. Since $f(x, y, z) = xy^2$ is continuous on E , we use Fubini's Theorem for triple integrals.

$$\begin{aligned}\iiint_E xy^2 dV &= \int_0^1 \int_0^1 \int_0^4 xy^2 dz dy dx = \int_0^1 \int_0^1 xy^2 [z]_0^4 dy dx = \int_0^1 \int_0^1 4xy^2 dy dx \\ &= \int_0^1 4x \left[\frac{1}{3}y^3 \right]_0^1 dx = \int_0^1 \frac{4}{3}x dx = \left[\frac{2}{3}x^2 \right]_0^1 = \boxed{\frac{2}{3}}\end{aligned}$$

6. Since $f(x, y, z) = x^2yz$ is continuous on E , we use Fubini's Theorem for triple integrals.

$$\begin{aligned}\iiint_E x^2yz dV &= \int_0^2 \int_0^1 \int_0^2 x^2yz dz dy dx = \int_0^2 \int_0^1 x^2y \left[\frac{1}{2}z^2 \right]_0^2 dy dx = \int_0^2 \int_0^1 2x^2y dy dx \\ &= \int_0^2 2x^2 \left[\frac{1}{2}y^2 \right]_0^1 dx = \int_0^2 x^2 dx = \left[\frac{1}{3}x^3 \right]_0^2 = \boxed{\frac{8}{3}}\end{aligned}$$

7. Since $f(x, y, z) = x^2 + y^2 + z^2$ is continuous on E , we use Fubini's Theorem for triple integrals.

$$\begin{aligned}\iiint_E (x^2 + y^2 + z^2) dV &= \int_0^1 \int_0^1 \int_0^1 (x^2 + y^2 + z^2) dz dy dx = \int_0^1 \int_0^1 \left[x^2z + y^2z + \frac{1}{3}z^3 \right]_0^1 dy dx \\ &= \int_0^1 \int_0^1 \left(x^2 + y^2 + \frac{1}{3} \right) dy dx = \int_0^1 \left[x^2y + \frac{1}{3}y^3 + \frac{1}{3}y \right]_0^1 dx \\ &= \int_0^1 \left(x^2 + \frac{2}{3} \right) dx = \left[\frac{1}{3}x^3 + \frac{2}{3}x \right]_0^1 = \boxed{1}\end{aligned}$$

8. Since $f(x, y, z) = x^2 - y^2 + z^2$ is continuous on E , we use Fubini's Theorem for triple integrals.

$$\begin{aligned}\iiint_E (x^2 - y^2 + z^2) dV &= \int_0^1 \int_0^2 \int_0^1 (x^2 - y^2 + z^2) dz dy dx = \int_0^1 \int_0^2 \left[x^2z - y^2z + \frac{1}{3}z^3 \right]_0^1 dy dx \\ &= \int_0^1 \int_0^2 \left(x^2 - y^2 + \frac{1}{3} \right) dy dx = \int_0^1 \left[x^2y - \frac{1}{3}y^3 + \frac{1}{3}y \right]_0^2 dx \\ &= \int_0^1 (2x^2 - 2) dx = \left[\frac{2}{3}x^3 - 2x \right]_0^1 = \boxed{-\frac{4}{3}}\end{aligned}$$

9. Since $f(x, y, z) = e^z \sin x \cos y$ is continuous on E , we use Fubini's Theorem for triple integrals.

$$\begin{aligned} \iiint_E e^z \sin x \cos y \, dV &= \int_0^{\pi/2} \int_0^{\pi/2} \int_0^1 e^z \sin x \cos y \, dz \, dy \, dx = \int_0^{\pi/2} \int_0^{\pi/2} \sin x \cos y [e^z]_0^1 \, dy \, dx \\ &= \int_0^{\pi/2} \int_0^{\pi/2} (e - 1) \sin x \cos y \, dy \, dx = \int_0^{\pi/2} (e - 1) \sin x [\sin y]_0^{\pi/2} \, dx \\ &= \int_0^{\pi/2} (e - 1) \sin x \, dx = (e - 1) [(-\cos x)]_0^{\pi/2} = \boxed{e - 1} \end{aligned}$$

10. Since $f(x, y, z) = e^{-z} \cos x \cos y$ is continuous on E , we use Fubini's Theorem for triple integrals.

$$\begin{aligned} \iiint_E e^{-z} \cos x \cos y \, dV &= \int_0^{\pi/2} \int_0^{\pi/2} \int_0^1 e^{-z} \cos x \cos y \, dz \, dy \, dx = \int_0^{\pi/2} \int_0^{\pi/2} \cos x \cos y [-e^{-z}]_0^1 \, dy \, dx \\ &= \int_0^{\pi/2} \int_0^{\pi/2} \left(1 - \frac{1}{e}\right) \cos x \cos y \, dy \, dx = \int_0^{\pi/2} \left(1 - \frac{1}{e}\right) \cos x [\sin y]_0^{\pi/2} \, dx \\ &= \int_0^{\pi/2} \left(1 - \frac{1}{e}\right) \cos x \, dx = \left(1 - \frac{1}{e}\right) [\sin x]_0^{\pi/2} = \boxed{1 - \frac{1}{e}} \end{aligned}$$

11. Since $f(x, y, z) = x$ is continuous for all real numbers, we use Fubini's Theorem for triple integrals.

$$\begin{aligned} \int_0^2 \int_0^{2-3x} \int_0^{x+y} x \, dz \, dy \, dx &= \int_0^2 \int_0^{2-3x} x [z]_0^{x+y} \, dy \, dx = \int_0^2 \int_0^{2-3x} (x^2 + xy) \, dy \, dx \\ &= \int_0^2 \left[x^2 y + \frac{1}{2} x y^2 \right]_0^{2-3x} \, dx = \int_0^2 [(2-3x)x^2 + \frac{1}{2} x(2-3x)^2] \, dx \\ &= \int_0^2 \left[2x^2 - 3x^3 + \frac{1}{2} x(4 - 12x + 9x^2) \right] \, dx = \int_0^2 \left(\frac{3}{2} x^3 - 4x^2 + 2x \right) \, dx \\ &= \left[\frac{3}{8} x^4 - \frac{4}{3} x^3 + x^2 \right]_0^2 = \boxed{-\frac{2}{3}} \end{aligned}$$

12. Since $f(x, y, z) = z$ is continuous for all real numbers, we use Fubini's Theorem for triple integrals.

$$\begin{aligned} \int_0^1 \int_0^{-x} \int_0^{2x+y} z \, dz \, dy \, dx &= \int_0^1 \int_0^{-x} \left[\frac{1}{2} z^2 \right]_0^{2x+y} \, dy \, dx = \int_0^1 \int_0^{-x} \left(2x^2 + 2xy + \frac{1}{2} y^2 \right) \, dy \, dx \\ &= \int_0^1 \left[2x^2 y + xy^2 + \frac{1}{6} y^3 \right]_0^{-x} \, dx = \int_0^1 \left(-2x^3 + x^3 - \frac{1}{6} x^3 \right) \, dx \\ &= \int_0^1 -\frac{7}{6} x^3 \, dx = \left[-\frac{7}{24} x^4 \right]_0^1 = \boxed{-\frac{7}{24}} \end{aligned}$$

13. Since $f(x, y, z) = 2x + 1$ is continuous for all real numbers, we use Fubini's Theorem for triple integrals.

$$\begin{aligned} \int_0^3 \int_z^{z+2} \int_y^{y+z} (2x + 1) \, dx \, dy \, dz &= \int_0^3 \int_z^{z+2} [x^2 + x]_y^{y+z} \, dy \, dz \\ &= \int_0^3 \int_z^{z+2} [y^2 + 2yz + z^2 + y + z - (y^2 + y)] \, dy \, dz \\ &= \int_0^3 \int_z^{z+2} (2yz + z^2 + z) \, dy \, dz = \int_0^3 [y^2 z + yz^2 + yz]_z^{z+2} \, dz \\ &= \int_0^3 [z(z^2 + 4z + 4) + z^2(z + 2) + z(z + 2) - (z^3 + z^3 + z^2)] \, dz \\ &= \int_0^3 (6z^2 + 6z) \, dz = [2z^3 + 3z^2]_0^3 = \boxed{81} \end{aligned}$$

14. Since $f(x, y, z) = 4z - 1$ is continuous for all real numbers, we use Fubini's Theorem for triple integrals.

$$\begin{aligned}
 \int_0^2 \int_y^{y+2} \int_y^{x+y} (4z - 1) dz dx dy &= \int_0^2 \int_y^{y+2} [2z^2 - z]_y^{x+y} dx dy \\
 &= \int_0^2 \int_y^{y+2} [2x^2 + 4xy + 2y^2 - (x + y) - (2y^2 - y)] dx dy \\
 &= \int_0^2 \int_y^{y+2} (2x^2 + 4xy - x) dx dy = \int_0^2 \left[\frac{2}{3}x^3 + 2x^2y - \frac{1}{2}x^2 \right]_y^{y+2} dy \\
 &= \int_0^2 \left(12y^2 + 14y + \frac{10}{3} \right) dy = \left[4y^3 + 7y^2 + \frac{10}{3}y \right]_0^2 = \boxed{\frac{200}{3}}
 \end{aligned}$$

15. Since $f(x, y, z) = e^x$ is continuous for all real numbers, we use Fubini's Theorem for triple integrals.

$$\begin{aligned}
 \int_0^2 \int_0^1 \int_0^y e^x dx dy dz &= \int_0^2 \int_0^1 [e^x]_0^y dy dz = \int_0^2 \int_0^1 (e^y - 1) dy dz \\
 &= \int_0^2 [e^y - y]_0^1 dz = \int_0^2 (e - 2) dz = (e - 2)[z]_0^2 = \boxed{2(e - 2)}
 \end{aligned}$$

16. Since $f(x, y, z) = xe^{x^2}$ is continuous for all real numbers, we use Fubini's Theorem for triple integrals. To integrate with respect to x , we use the substitution $u = x^2$. Then $du = 2x dx$ or $\frac{1}{2}du = x dx$, and the limits of integration become $u = 0$ to $u = y$.

$$\begin{aligned}
 \int_1^2 \int_0^z \int_0^{\sqrt{y}} xe^{x^2} dx dy dz &= \frac{1}{2} \int_1^2 \int_0^z \int_0^y e^u du dy dz = \frac{1}{2} \int_1^2 \int_0^z [e^u]_0^y dy dz \\
 &= \frac{1}{2} \int_1^2 \int_0^z (e^y - 1) dy dz = \frac{1}{2} \int_1^2 [e^y - y]_0^z dz = \frac{1}{2} \int_1^2 (e^z - z - 1) dz \\
 &= \frac{1}{2} \left[e^z - \frac{1}{2}z^2 - z \right]_1^2 = \frac{1}{2} \left[e^2 - 2 - 2 - \left(e - \frac{1}{2} - 1 \right) \right] = \frac{1}{2} \left(e^2 - e - \frac{5}{2} \right) \\
 &= \boxed{\frac{e^2}{2} - \frac{e}{2} - \frac{5}{4}}
 \end{aligned}$$

17. To evaluate $f(x, y, z) = \sin\left(\frac{z}{y}\right)$, we use Fubini's Theorem for triple integrals.

$$\begin{aligned}
 \int_0^{\pi/2} \int_y^{\pi/2} \int_0^{xy} \sin\left(\frac{z}{y}\right) dz dx dy &= \int_0^{\pi/2} \int_y^{\pi/2} \left[-y \cos\left(\frac{z}{y}\right) \right]_0^{xy} dx dy \\
 &= \int_0^{\pi/2} \int_y^{\pi/2} (-y \cos x + y) dx dy = \int_0^{\pi/2} [-y \sin x + xy]_y^{\pi/2} dy \\
 &= \int_0^{\pi/2} \left(-y + \frac{\pi}{2}y + y \sin y - y^2 \right) dy \\
 &= \left[-\frac{1}{2}y^2 + \frac{\pi}{4}y^2 - y \cos y + \sin y - \frac{1}{3}y^3 \right]_0^{\pi/2} \\
 &= -\frac{\pi^2}{8} + \frac{\pi^3}{16} + 1 - \frac{\pi^3}{24} = \boxed{1 - \frac{\pi^2}{8} + \frac{\pi^3}{48}}
 \end{aligned}$$

18. To evaluate $f(x, y, z) = \cos\left(\frac{z}{x}\right)$, we use Fubini's Theorem for triple integrals.

$$\begin{aligned} \int_0^{\pi/2} \int_x^{\pi/2} \int_0^{xy} \cos\left(\frac{z}{x}\right) dz dy dx &= \int_0^{\pi/2} \int_x^{\pi/2} \left[x \sin\left(\frac{z}{x}\right) \right]_0^{xy} dy dx \\ &= \int_0^{\pi/2} \int_x^{\pi/2} x \sin y dy dx = \int_0^{\pi/2} [-x \cos y]_x^{\pi/2} dx \\ &= \int_0^{\pi/2} x \cos x dx = [x \sin x + \cos x]_0^{\pi/2} = \boxed{\frac{\pi}{2} - 1} \end{aligned}$$

19. Since $0 \leq z \leq 5 - x - y$, E is xy -simple.

The region R in the xy -plane is enclosed by the x -axis, the y -axis, and the lines $x = 1$ and $y = 3$, so R is both x - and y -simple.

Treating R as x -simple,

$$\begin{aligned} \iiint_E xy dV &= \int_0^1 \int_0^3 \int_0^{5-x-y} xy dz dy dx = \int_0^1 \int_0^3 xy [z]_0^{5-x-y} dy dx = \int_0^1 \int_0^3 (5xy - x^2y - xy^2) dy dx \\ &= \int_0^1 \left[\frac{5}{2}xy^2 - \frac{1}{2}x^2y^2 - \frac{1}{3}xy^3 \right]_0^3 dx = \int_0^1 \left(\frac{45}{2}x - \frac{9}{2}x^2 - 9x \right) dx = \left[\frac{45}{4}x^2 - \frac{3}{2}x^3 - \frac{9}{2}x^2 \right]_0^1 \\ &= \frac{45}{4} - \frac{3}{2} - \frac{9}{2} = \boxed{\frac{21}{4}} \end{aligned}$$

20. Since $0 \leq z \leq 16 - x^2 - y^2$, E is xy -simple.

The region R in the xy -plane is enclosed by the x -axis, the y -axis, and the lines $x = 2$ and $y = 1$, so R is both x - and y -simple.

Treating R as x -simple,

$$\begin{aligned}
 \iiint_E xy \, dV &= \int_0^2 \int_0^1 \int_0^{16-x^2-y^2} xy \, dz \, dy \, dx = \int_0^2 \int_0^1 xy [z]_0^{16-x^2-y^2} \, dy \, dx \\
 &= \int_0^2 \int_0^1 (16xy - x^3y - xy^3) \, dy \, dx = \int_0^2 \left[8xy^2 - \frac{1}{2}x^3y^2 - \frac{1}{4}xy^4 \right]_0^1 \, dx \\
 &= \int_0^2 \left(8x - \frac{1}{2}x^3 - \frac{1}{4}x \right) \, dx = \left[4x^2 - \frac{1}{8}x^4 - \frac{1}{8}x^2 \right]_0^2 = \boxed{\frac{27}{2}}
 \end{aligned}$$

21. Since $0 \leq z \leq xy$, E is xy -simple.

The region R in the xy -plane is the triangle enclosed by the x -axis, the y -axis, and the line $y = 1 - x$, so R is both x - and y -simple.

Treating R as x -simple,

$$\begin{aligned}
 \iiint_E xy \, dV &= \int_0^1 \int_0^{1-x} \int_0^{xy} xy \, dz \, dy \, dx = \int_0^1 \int_0^{1-x} xy [z]_0^{xy} \, dy \, dx = \int_0^1 \int_0^{1-x} x^2 y^2 \, dy \, dx \\
 &= \int_0^1 \frac{1}{3} x^2 [y^3]_0^{1-x} \, dx = \int_0^1 \frac{1}{3} x^2 (1 - 3x + 3x^2 - x^3) \, dx = \int_0^1 \left(\frac{1}{3} x^2 - x^3 + x^4 - \frac{1}{3} x^5 \right) \, dx \\
 &= \left[\frac{1}{9} x^3 - \frac{1}{4} x^4 + \frac{1}{5} x^5 - \frac{1}{18} x^6 \right]_0^1 = \frac{1}{9} - \frac{1}{4} + \frac{1}{5} - \frac{1}{18} = \boxed{\frac{1}{180}}
 \end{aligned}$$

22. Since $0 \leq z \leq x^2 + y^2$, E is xy -simple.

The region R in the xy -plane is the triangle enclosed by the x -axis, the y -axis, and the line $y = 2 - 2x$, so R is both x - and y -simple.

Treating R as x -simple,

$$\begin{aligned}
 \iiint_E xy \, dV &= \int_0^1 \int_0^{2-2x} \int_0^{x^2+y^2} xy \, dz \, dy \, dx = \int_0^1 \int_0^{2-2x} xy [z]_0^{x^2+y^2} \, dy \, dx \\
 &= \int_0^1 \int_0^{2-2x} (x^3y + xy^3) \, dy \, dx = \int_0^1 \left[\frac{1}{2}x^3y^2 + \frac{1}{4}xy^4 \right]_0^{2-2x} \, dx \\
 &= \int_0^1 \left[\frac{1}{2}x^3(4-8x+4x^2) + \frac{1}{4}x(16-64x+96x^2-64x^3+16x^4) \right] \, dx \\
 &= \int_0^1 (6x^5 - 20x^4 + 26x^3 - 16x^2 + 4x) \, dx = \left[x^6 - 4x^5 + \frac{13}{2}x^4 - \frac{16}{3}x^3 + 2x^2 \right]_0^1 = \boxed{\frac{1}{6}}
 \end{aligned}$$

23. Since $0 \leq z \leq 3 - x - y$, E is xy -simple.

The region R in the xy -plane is the triangle enclosed by the lines $y = x$ and $y = -x$, so R is x -simple.

Then

$$\begin{aligned}
 \iiint_E xy \, dV &= \int_0^1 \int_{-x}^x \int_0^{3-x-y} xy \, dz \, dy \, dx = \int_0^1 \int_{-x}^x xy [z]_0^{3-x-y} \, dy \, dx \\
 &= \int_0^1 \int_{-x}^x (3xy - x^2y - xy^2) \, dy \, dx = \int_0^1 \left[\frac{3}{2}xy^2 - \frac{1}{2}x^2y^2 - \frac{1}{3}xy^3 \right]_{-x}^x \, dx \\
 &= \int_0^1 -\frac{2}{3}x^4 \, dx = \left[-\frac{2}{15}x^5 \right]_0^1 = \boxed{-\frac{2}{15}}
 \end{aligned}$$

24. Since $0 \leq z \leq 3 + 2y$, E is xy -simple.

The region R in the xy -plane is the triangle enclosed by the x -axis and the lines $x = y - 1$ and $x = 2 - 2y$, so R is y -simple.

Then

$$\begin{aligned}
 \iiint_E xy \, dV &= \int_0^1 \int_{y-1}^{2-2y} \int_0^{3+2y} xy \, dz \, dx \, dy = \int_0^1 \int_{y-1}^{2-2y} xy [z]_0^{3+2y} \, dx \, dy \\
 &= \int_0^1 \int_{y-1}^{2-2y} (3xy + 2xy^2) \, dx \, dy = \int_0^1 \left[\frac{3}{2}x^2y + x^2y^2 \right]_{y-1}^{2-2y} dy \\
 &= \int_0^1 \left[6y - 12y^2 + 6y^3 + 4y^2 - 8y^3 + 4y^4 - \left(\frac{3}{2}y^3 - 3y^2 + \frac{3}{2}y + y^4 - 2y^3 + y^2 \right) \right] dy \\
 &= \int_0^1 \left(3y^4 - \frac{3}{2}y^3 - 6y^2 + \frac{9}{2}y \right) dy = \left[\frac{3}{5}y^5 - \frac{3}{8}y^4 - 2y^3 + \frac{9}{4}y^2 \right]_0^1 = \boxed{\frac{19}{40}}
 \end{aligned}$$

25. Using MapleTM,

$$\int_0^1 \int_1^{x^2} \int_0^{\sqrt{x}} ye^x \, dz \, dy \, dx \approx \boxed{-0.4142}.$$

26. Using MapleTM,

$$\int_3^4 \int_2^3 \int_0^1 \ln(x^2 + y^2 + z^2) \, dx \, dy \, dz \approx \boxed{2.9356}.$$

Applications and Extensions

27. The tetrahedron is bounded by four planes.

The points $(0, 0, 0)$, $(1, 1, 0)$, and $(1, 0, 0)$ all have a z -coordinate of 0, which means that the tetrahedron is bounded by the plane $z = 0$, or the xy -plane. Similarly, the tetrahedron is bounded by the xz -plane and the plane $x = 1$. Using the points $(0, 0, 0)$, $(1, 1, 0)$, and $(1, 0, 1)$, we find that the vectors $\mathbf{v} = \mathbf{i} + \mathbf{j}$ and $\mathbf{w} = \mathbf{i} + \mathbf{k}$ lie in the fourth plane, so the vector $\mathbf{N} = \mathbf{v} \times \mathbf{w} = \mathbf{i} - \mathbf{j} - \mathbf{k}$ is normal to the plane. Using the point $(0, 0, 0)$, the equation of the plane is $x - y - z = 0$ or $z = x - y$. Then $0 \leq z \leq x - y$, and E is xy -simple.

The region R in the xy -plane is the triangle enclosed by the x -axis, the y -axis, and the line $y = x$, so R is both x - and y -simple.

Treating R as x -simple,

$$\begin{aligned} \iiint_E x \, dV &= \int_0^1 \int_0^x \int_0^{x-y} x \, dz \, dy \, dx = \int_0^1 \int_0^x x [z]_0^{x-y} \, dy \, dx = \int_0^1 \int_0^x (x^2 - xy) \, dy \, dx \\ &= \int_0^1 \left[x^2 y - \frac{1}{2} xy^2 \right]_0^x \, dx = \int_0^1 \left(x^3 - \frac{1}{2} x^3 \right) \, dx = \int_0^1 \frac{1}{2} x^3 \, dx = \left[\frac{1}{8} x^4 \right]_0^1 = \boxed{\frac{1}{8}} \end{aligned}$$

28. See the figures and explanation of the equations for the planes of the tetrahedron in Problem 27.

Treating R as x -simple,

$$\begin{aligned}
 \iiint_E (x^2 + z^2) dV &= \int_0^1 \int_0^x \int_0^{x-y} (x^2 + z^2) dz dy dx = \int_0^1 \int_0^x \left[x^2 z + \frac{1}{3} z^3 \right]_0^{x-y} dy dx \\
 &= \int_0^1 \int_0^x \left[x^3 - x^2 y + \frac{1}{3} (x^3 - 3x^2 y + 3xy^2 - y^3) \right] dy dx \\
 &= \int_0^1 \int_0^x \left(\frac{4}{3} x^3 - 2x^2 y + xy^2 - \frac{1}{3} y^3 \right) dy dx \\
 &= \int_0^1 \left[\frac{4}{3} x^3 y - x^2 y^2 + \frac{1}{3} xy^3 - \frac{1}{12} y^4 \right]_0^x dx = \int_0^1 \left(\frac{4}{3} x^4 - x^4 + \frac{1}{3} x^4 - \frac{1}{12} x^4 \right) dx \\
 &= \int_0^1 \frac{7}{12} x^4 dx = \left[\frac{7}{60} x^5 \right]_0^1 = \boxed{\frac{7}{60}}
 \end{aligned}$$

29. Since $0 \leq z \leq 3 - x$, E is xy -simple.

The region R in the xy -plane is the region enclosed by x -axis and the semicircle $y = \sqrt{9 - x^2}$, so R is x -simple.

Then

$$\begin{aligned}
 \iiint_E (xy + 3y) dV &= \int_{-3}^3 \int_0^{\sqrt{9-x^2}} \int_0^{3-x} (xy + 3y) dz dy dx = \int_{-3}^3 \int_0^{\sqrt{9-x^2}} [xyz + 3yz]_0^{3-x} dy dx \\
 &= \int_{-3}^3 \int_0^{\sqrt{9-x^2}} (3xy - x^2y + 9y - 3xy) dy dx = \int_{-3}^3 \int_0^{\sqrt{9-x^2}} (9y - x^2y) dy dx \\
 &= \int_{-3}^3 \left[\frac{9}{2}y^2 - \frac{1}{2}x^2y^2 \right]_0^{\sqrt{9-x^2}} dx = \int_{-3}^3 \left[\frac{9}{2}(9-x^2) - \frac{1}{2}x^2(9-x^2) \right] dx \\
 &= \int_{-3}^3 \left(\frac{81}{2} - 9x^2 + \frac{1}{2}x^4 \right) dx = \left[\frac{81}{2}x - 3x^3 + \frac{1}{10}x^5 \right]_{-3}^3 \\
 &= \left(\frac{243}{2} - 81 + \frac{243}{10} \right) - \left(-\frac{243}{2} + 81 - \frac{243}{10} \right) = \boxed{\frac{648}{5}}
 \end{aligned}$$

30. Since $x^2 + z^2 = 1$, $-\sqrt{1-x^2} \leq z \leq \sqrt{1-x^2}$, so E is xy -simple.

The region R in the xy -plane is bounded by the unit circle, so R is both x - and y -simple.

Treating R as x -simple,

$$\begin{aligned}
 \iiint_E xyz dV &= \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} xyz dz dy dx = \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} xy \left[\frac{1}{2}z^2 \right]_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} dy dx \\
 &= \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{2}xy[(1-x^2) - (1-x^2)] dy dx = \boxed{0}
 \end{aligned}$$

31. (a) From the limits of integration, $0 \leq z \leq 1$, $0 \leq x \leq \sqrt{4 - y^2}$, and $-2 \leq y \leq 2$. The region R in the xy -plane is bounded by the right side of a semicircle of radius 2. Since $0 \leq z \leq 1$, the solid is the semicircle bounded by $x^2 + y^2 = 4$ and the planes $x = 0$, $z = 0$, and $z = 1$.

(b) The solid was generated using MapleTM.

32. (a) From the limits of integration, $0 \leq z \leq 4 - x^2 - y^2$, $0 \leq x \leq \sqrt{4 - y^2}$, and $0 \leq y \leq 2$. The graph of $z = 4 - x^2 - y^2$ is a paraboloid of revolution. Since $x = \sqrt{4 - y^2}$ is a semicircle of radius 2 and both y and z are restricted to positive values, the solid is a paraboloid of revolution in the first octant.

(b) The solid was generated using MapleTM.

33. (a) From the limits of integration, $0 \leq z \leq y$, $0 \leq y \leq x^2$, and $0 \leq x \leq 1$. The solid is bounded by $y = x^2$ and the planes $z = 0$, $x = 1$, and $z = y$.

(b) The solid was generated using MapleTM.

34. (a) From the limits of integration, $0 \leq y \leq 1$, $y^2 \leq x \leq 1$, and $0 \leq z \leq 1 - x$. The solid is bounded by $x = y^2$ and the planes $y = 0$, $y = 1$, $z = 0$, and $z = 1 - x$.
 (b) The solid was generated using Maple™.

35. The solid E is enclosed by the parabolic cylinder $z = y^2$ and the planes $x = 0$ and $x = y - z$, which is xy -simple. The upper surface is the plane $z = y - x$, and the lower surface is the parabolic cylinder $z = y^2$.

The parabolic cylinder and the plane intersect at $y^2 = y - x$ or $x = y - y^2$. Then the region R is described by $0 \leq x \leq y - y^2$ and $0 \leq y \leq 1$ and is x -simple.

Then

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^1 \int_0^{y-y^2} \int_{y^2}^{y-x} dz \, dx \, dy = \int_0^1 \int_0^{y-y^2} [z]_{y^2}^{y-x} \, dx \, dy = \int_0^1 \int_0^{y-y^2} (y-x-y^2) \, dx \, dy \\
 &= \int_0^1 \left[xy - \frac{1}{2}x^2 - xy^2 \right]_0^{y-y^2} dy = \int_0^1 \left[y^2 - y^3 - \frac{1}{2}(y^2 - 2y^3 + y^4) - (y^3 - y^4) \right] dy \\
 &= \int_0^1 \left(\frac{1}{2}y^4 - y^3 + \frac{1}{2}y^2 \right) dy = \left[\frac{1}{10}y^4 - \frac{1}{4}y^4 + \frac{1}{6}y^3 \right]_0^1 = \boxed{\frac{1}{60}}
 \end{aligned}$$

36. The solid E is yz -simple.

The front surface is the plane $x = 9 - z$, and the back surface is $x = 0$. The region R in the yz -plane is enclosed by $z = 0$ and the parabola $z = 4 - y^2$ and is z -simple.

Then the volume of E is

$$\begin{aligned}
 V &= \iiint_E dV = \int_{-2}^2 \int_0^{4-y^2} \int_0^{9-z} dx \, dz \, dy = \int_{-2}^2 \int_0^{4-y^2} [x]_0^{9-z} \, dz \, dy = \int_{-2}^2 \int_0^{4-y^2} (9-z) \, dz \, dy \\
 &= \int_{-2}^2 \left[9z - \frac{1}{2}z^2 \right]_0^{4-y^2} dy = \int_{-2}^2 \left[36 - 9y^2 - \frac{1}{2}(16 - 8y^2 + y^4) \right] dy = \int_{-2}^2 \left(-\frac{1}{2}y^4 - 5y^2 + 28 \right) dy \\
 &= 2 \int_0^2 \left(-\frac{1}{2}y^4 - 5y^2 + 28 \right) dy = 2 \left[-\frac{1}{10}y^5 - \frac{5}{3}y^3 + 28y \right]_0^2 = 2 \left(-\frac{32}{10} - \frac{40}{3} + 56 \right) = \boxed{\frac{1184}{15}}
 \end{aligned}$$

37. The region R is the projection in the xy -plane of the region enclosed by the circle $x^2 + y^2 = 1$ which can also be expressed by $-\sqrt{1-x^2} \leq y \leq \sqrt{1-x^2}$ and $-1 \leq x \leq 1$. The solid E is bounded by $z = 3 - x - y$ above and $z = 1 - x - y$ below and is xy -simple. Then

$$\iiint_E xy \, dV = \boxed{\int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{1-x-y}^{3-x-y} xy \, dz \, dy \, dx}$$

38. The region R is the projection in the xy -plane of the region enclosed by the circle $x^2 + y^2 = 4$ which can also be expressed by $-\sqrt{4-x^2} \leq y \leq \sqrt{4-x^2}$ and $-2 \leq x \leq 2$. The solid E is bounded by $z = x^2 + y$ above and $z = 0$ below and is xy -simple. Then

$$\iiint_E xy \, dV = \boxed{\int_{-2}^2 \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} \int_0^{x^2+y} xy \, dz \, dy \, dx}$$

39. The solid E is enclosed by the paraboloids of revolution $z = x^2 + y^2$ and $z = 16 - x^2 - y^2$.

The region R is bounded by the projection of the intersection of these paraboloids of revolution. Simplifying $x^2 + y^2 = 16 - x^2 - y^2$ gives the boundary for R as $x^2 + y^2 = 8$ which can also be expressed as $-\sqrt{8-x^2} \leq y \leq \sqrt{8-x^2}$, $-2\sqrt{2} \leq x \leq 2\sqrt{2}$.

Then using symmetry,

$$V = \iiint_E dV = \int_{-2\sqrt{2}}^{2\sqrt{2}} \int_{-\sqrt{8-x^2}}^{\sqrt{8-x^2}} \int_{x^2+y^2}^{16-x^2-y^2} dz \, dy \, dx = \boxed{4 \int_0^{\sqrt{8}} \int_0^{\sqrt{8-x^2}} \int_{x^2+y^2}^{16-x^2-y^2} dz \, dy \, dx}.$$

40. The solid E is enclosed by the paraboloid of revolution $z = x^2 + y^2$ and the plane $z = 2 - x$, and the region R is bounded by the projection of the intersection of these functions.

Simplifying $x^2 + y^2 = 2 - x$ gives $x^2 + x + y^2 = 2$. We complete the square.

$$\begin{aligned} x^2 + x + \left(\frac{1}{2}\right)^2 + y^2 &= 2 + \left(\frac{1}{2}\right)^2 \\ \left(x + \frac{1}{2}\right)^2 + y^2 &= \frac{9}{4} \end{aligned}$$

The boundary for the region R is a circle centered at $(-\frac{1}{2}, 0)$ with radius $r = \frac{3}{2}$, which can also be expressed as $-\sqrt{\frac{9}{4} - (x + \frac{1}{2})^2} \leq y \leq \sqrt{\frac{9}{4} - (x + \frac{1}{2})^2}$, $-2 \leq x \leq 1$.

Then

$$V = \iiint_E dV = \int_{-2}^1 \int_{-\sqrt{\frac{9}{4} - (x + \frac{1}{2})^2}}^{\sqrt{\frac{9}{4} - (x + \frac{1}{2})^2}} \int_{x^2 + y^2}^{2-x} dz \, dy \, dx$$

41. The solid E is enclosed by the parabolic cylinder $z^2 = 4x$ and the right circular cylinder $x^2 + y^2 = 2x$. Because $z^2 = 4x$, $-2\sqrt{x} \leq z \leq 2\sqrt{x}$. We note the symmetry with respect to the xy -plane.

We can use the projection on to the xy -plane as the region R . We complete the square in the equation $x^2 + y^2 = 2x$.

$$\begin{aligned} x^2 - 2x + \left(\frac{-2}{2}\right)^2 + y^2 &= \left(\frac{-2}{2}\right)^2 \\ (x - 1)^2 + y^2 &= 1 \end{aligned}$$

The boundary for the region R is a circle centered at $(1, 0)$ with radius $r = 1$, which can also be expressed as $-\sqrt{1 - (x - 1)^2} \leq y \leq \sqrt{1 - (x - 1)^2}$, $0 \leq x \leq 2$.

Then

$$V = \iiint_E dV = \int_0^2 \int_{-\sqrt{1-(x-1)^2}}^{\sqrt{1-(x-1)^2}} \int_{-2\sqrt{x}}^{2\sqrt{x}} dz dy dx = \boxed{4 \int_0^2 \int_0^{\sqrt{1-(x-1)^2}} \int_0^{2\sqrt{x}} dz dy dx}$$

42. (a) The solid E is enclosed by the elliptic cylinder $x^2 + 2y^2 = 1$ and the planes $z = x + 1$ and $z = 4$.

The region R is bounded by the ellipse $x^2 + 2y^2 = 1$ in the xy -plane, which can also be expressed as $-\sqrt{\frac{1-x^2}{2}} \leq y \leq \sqrt{\frac{1-x^2}{2}}$, $-1 \leq x \leq 1$. Then using symmetry,

$$V = \iiint_E dV = 4 \int_0^1 \int_0^{\sqrt{\frac{1-x^2}{2}}} \int_{x+1}^4 dz dy dx = \boxed{\frac{3\sqrt{2}}{2}\pi - \frac{2\sqrt{2}}{3}}.$$

- (b) The solid E

and the region R

43. Let a corner of the cube be located at the origin so that the distance between it and any point is $d = \sqrt{(x-0)^2 + (y-0)^2 + (z-0)^2} = \sqrt{x^2 + y^2 + z^2}$. The cube is xy -, yz -, and xz -simple, and any region R will be bounded by a square with side length a . We treat the cube as xy -simple and the region R as x -simple. Since the mass density is proportional to the square of the distance from one corner, $\rho = \rho(x, y, z) = kd^2 = k(x^2 + y^2 + z^2)$ where k is the constant of proportionality. We know the length of each side of the cube is a , so the mass M is

$$\begin{aligned}
 M &= \iiint_E \rho(x, y, z) dV = \iiint_E k(x^2 + y^2 + z^2) dV = \int_0^a \int_0^a \int_0^a k(x^2 + y^2 + z^2) dz dy dx \\
 &= \int_0^a \int_0^a k \left[x^2 z + y^2 z + \frac{1}{3} z^3 \right]_0^a dy dx = \int_0^a \int_0^a k \left(ax^2 + ay^2 + \frac{1}{3} a^3 \right) dy dx \\
 &= \int_0^a k \left[ax^2 y + \frac{1}{3} ay^3 + \frac{1}{3} a^3 y \right]_0^a dx = \int_0^a k \left(a^2 x^2 + \frac{1}{3} a^4 + \frac{1}{3} a^4 \right) dx = \int_0^a k \left(a^2 x^2 + \frac{2}{3} a^4 \right) dx \\
 &= k \left[\frac{1}{3} a^2 x^3 + \frac{2}{3} a^4 x \right]_0^a = k \left(\frac{1}{3} a^5 + \frac{2}{3} a^5 \right) = \boxed{ka^5}.
 \end{aligned}$$

44. Let the axis of the cylinder be the z -axis. For any point (x, y, z) in the cylinder, the closest point on the axis will be $(0, 0, z)$, so the distance between a point and the axis is

$$d = \sqrt{(x-0)^2 + (y-0)^2 + (z-z)^2} = \sqrt{x^2 + y^2}.$$

The cylinder is bounded by $z = 0$ below and $z = h$ above, so it is xy -simple. The region R in the xy -plane is bounded by a circle of radius a and is both x - and y -simple. We treat R as x -simple. Since the mass density is proportional to the square of the distance from the axis to the cylinder, $\rho = \rho(x, y, z) = kd^2 = k(x^2 + y^2)$ where k is the constant of proportionality. Then the mass M is

$$\begin{aligned}
 M &= \iiint_E \rho(x, y, z) dV = \iiint_E k(x^2 + y^2) dz dy dx = \int_{-a}^a \int_{-\sqrt{a^2-x^2}}^{\sqrt{a^2-x^2}} \int_0^h dz dy dx \\
 &= \boxed{4 \int_0^a \int_0^{\sqrt{a^2-x^2}} \int_0^h dz dy dx}.
 \end{aligned}$$

45. For any point (x, y, z) in the tetrahedron, the closest point on the xy -plane will be $(x, y, 0)$, so the distance between a point and the xy -plane is $d_{xy} = \sqrt{(x-x)^2 + (y-y)^2 + (z-0)^2} = z$. Similarly, the distance from the point to the other coordinate planes will be $d_{yz} = x$ and $d_{xz} = y$. The tetrahedron is bounded by $z = 0$ below and $z = 1 - x - y$ above, so it is xy -simple. The region R in the xy -plane is bounded by the x -axis, the y -axis, and the line $y = 1 - x$ and is both x - and y -simple. We treat R as x -simple. Since the mass density is proportional to the product of the distances from the three coordinate

planes, $\rho = \rho(x, y, z) = k(d_{xy})(d_{yz})(d_{xz}) = k(xyz)$ where k is the constant of proportionality. Then the mass M is

$$M = \iiint_E \rho(x, y, z) dV = \iiint_E k(xyz) dz dy dx = \boxed{\int_0^1 \int_0^{1-x} \int_0^{1-x-y} k(xyz) dz dy dx}.$$

46. The cylinder is yz -simple. It is bounded by $x = L$ above and $x = -L$ below. The region R is bounded by a circle with equation $y^2 + z^2 = R^2$. Then since the mass density is $\rho(x, y, z) = kz^2$,

$$\begin{aligned} M &= \iiint_E \rho(x, y, z) dV = \iiint_E kz^2 dV = \int_{-R}^R \int_{-\sqrt{R^2-z^2}}^{\sqrt{R^2-z^2}} \int_{-L}^L kz^2 dx dy dz \\ &= 8 \int_0^R \int_0^{\sqrt{R^2-z^2}} \int_0^L kz^2 dx dy dz = 8 \int_0^R \int_0^{\sqrt{R^2-z^2}} kz^2 [x]_0^L dy dz \\ &= 8 \int_0^R \int_0^{\sqrt{R^2-z^2}} kLz^2 dy dz = 8 \int_0^R kLz^2 [y]_0^{\sqrt{R^2-z^2}} dz = 8 \int_0^R kLz^2 \sqrt{R^2 - z^2} dz. \end{aligned}$$

Using MapleTM with the assumptions that R and L are positive,

$$8 \int_0^R kLz^2 \sqrt{R^2 - z^2} dz = \boxed{\frac{\pi}{2} kR^4 L}.$$

47. The moment of inertia about the x -axis is

$$I_x = \iiint_E r^2 \rho dV$$

where $r = \sqrt{y^2 + z^2}$ is the distance of the point (x, y, z) from the x -axis. The hemisphere is xy -simple, and the region R is enclosed by the circle $x^2 + y^2 = 9$. R is both x - and y -simple. Since the mass density $\rho = \rho(x, y, z)$ is proportional to the distance from the xy -plane, $\rho(x, y, z) = kz$, where k is the constant of proportionality. Then

$$I_x = \iiint_E r^2 \rho(x, y, z) dV = \iiint_E (y^2 + z^2)(kz) dV = \boxed{\int_{-3}^3 \int_{-\sqrt{9-x^2}}^{\sqrt{9-x^2}} \int_0^{\sqrt{9-x^2-y^2}} k(y^2 + z^2)z dz dy dx}.$$

Similarly, the moment of inertia about the y -axis is

$$I_y = \iiint_E r^2 \rho dV$$

where $r = \sqrt{x^2 + z^2}$ is the distance of the point (x, y, z) from the y -axis, so

$$I_y = \iiint_E r^2 \rho(x, y, z) dV = \iiint_E (x^2 + z^2)(kz) dV = \boxed{\int_{-3}^3 \int_{-\sqrt{9-x^2}}^{\sqrt{9-x^2}} \int_0^{\sqrt{9-x^2-y^2}} k(x^2 + z^2)z dz dy dx}.$$

48. The solid is xy -simple. The top surface is the plane $z = 3$ and the bottom surface is the cone $z^2 = 3x^2 + 3y^2$. The region R in the xy -plane is enclosed by the circle $x^2 + y^2 = 3$, and it is both x - and y -simple. Then

$$\iiint_E x^2 yz dV = \boxed{\int_{-\sqrt{3}}^{\sqrt{3}} \int_{-\sqrt{3-x^2}}^{\sqrt{3-x^2}} \int_{\sqrt{3x^2+3y^2}}^3 x^2 yz dz dy dx}.$$

49. The tetrahedron E is xy -, yz -, and xz -simple.

First we consider the tetrahedron as an xy -simple solid so that $0 \leq z \leq 2 - \frac{x}{3} - \frac{2y}{3}$. The region R is bounded by the x - and y -axes and the line $x + 2y = 6$.

Treating R as x -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^6 \int_0^{3-\frac{x}{2}} \int_0^{2-\frac{x}{3}-\frac{2y}{3}} f(x, y, z) dz dy dx$$

while treating R as y -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^3 \int_0^{6-2y} \int_0^{2-\frac{x}{3}-\frac{2y}{3}} f(x, y, z) dz dx dy.$$

Next we consider the tetrahedron as a yz -simple solid so $0 \leq x \leq 6 - 2y - 3z$. The region R is bounded by the y - and z -axes and the line $2y + 3z = 6$.

Treating R as y -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^3 \int_0^{2-\frac{2y}{3}} \int_0^{6-2y-3z} f(x, y, z) dx dz dy$$

while treating R as z -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^2 \int_0^{3-\frac{3z}{2}} \int_0^{6-2y-3z} f(x, y, z) dx dy dz.$$

Finally we consider the tetrahedron as an xz -simple solid so that $0 \leq y \leq 3 - \frac{x}{2} - \frac{3z}{2}$. The region R is bounded by the x - and z -axes and the line $x + 3z = 6$.

Treating R as x -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^6 \int_0^{2-\frac{x}{3}} \int_0^{3-\frac{x}{2}-\frac{3z}{2}} f(x, y, z) dy dz dx$$

while treating R as z -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^2 \int_0^{6-3z} \int_0^{3-\frac{x}{2}-\frac{3z}{2}} f(x, y, z) dy dx dz.$$

50. The tetrahedron E is xy -, yz -, and xz -simple.

First we consider the tetrahedron as an xy -simple solid so that $0 \leq z \leq 3 - x - y$. The region R is bounded by the x - and y -axes and the line $x + y = 3$.

Treating R as x -simple gives

$$\iiint_E f(x, y, z) dV = \boxed{\int_0^3 \int_0^{3-x} \int_0^{3-x-y} f(x, y, z) dz dy dx}$$

while treating R as y -simple gives

$$\iiint_E f(x, y, z) dV = \boxed{\int_0^3 \int_0^{3-y} \int_0^{3-x-y} f(x, y, z) dz dx dy}.$$

Next we consider the tetrahedron as a yz -simple solid so $0 \leq x \leq 3 - y - z$. The region R is bounded by the y - and z -axes and the line $y + z = 3$.

Treating R as y -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^3 \int_0^{3-y} \int_0^{3-y-z} f(x, y, z) dx dz dy$$

while treating R as z -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^3 \int_0^{3-z} \int_0^{3-y-z} f(x, y, z) dx dy dz.$$

Finally we consider the tetrahedron as an xz -simple solid so that $0 \leq y \leq 3 - x - z$. The region R is bounded by the x - and z -axes and the line $x + z = 3$.

Treating R as x -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^3 \int_0^{3-x} \int_0^{3-x-z} f(x, y, z) dy dz dx$$

while treating R as z -simple gives

$$\iiint_E f(x, y, z) dV = \int_0^3 \int_0^{3-z} \int_0^{3-x-z} f(x, y, z) dy dx dz.$$

51. We begin by solving the equation for the ellipsoid, $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$, for z to find

$$-c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}} \leq z \leq c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}}.$$

The region R in the xy -plane is bounded by the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, so

$$-b\sqrt{1 - \frac{x^2}{a^2}} \leq y \leq b\sqrt{1 - \frac{x^2}{a^2}}$$

and $-a \leq x \leq a$. Then using symmetry, the volume of the ellipsoid is

$$\begin{aligned} V &= \iiint_E dV = 8 \int_0^a \int_0^{b\sqrt{1-\frac{x^2}{a^2}}} \int_0^{c\sqrt{1-\frac{x^2}{a^2}-\frac{y^2}{b^2}}} dz dy dx \\ &= 8 \int_0^a \int_0^{b\sqrt{1-\frac{x^2}{a^2}}} [z]_0^{c\sqrt{1-\frac{x^2}{a^2}-\frac{y^2}{b^2}}} dy dx = 8 \int_0^a \int_0^{b\sqrt{1-\frac{x^2}{a^2}}} c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}} dy dx. \end{aligned}$$

To evaluate $\int_0^{b\sqrt{1-\frac{x^2}{a^2}}} c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}} dy$, we use the substitution $u = \frac{y}{b}$ so $du = \frac{dy}{b}$ or $b du = dy$. The limits of integration become $u = 0$ to $u = \sqrt{1 - \frac{x^2}{a^2}}$.

$$\int_0^{b\sqrt{1-\frac{x^2}{a^2}}} c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}} dy = \int_0^{\sqrt{1-\frac{x^2}{a^2}}} bc\sqrt{1 - \frac{x^2}{a^2} - u^2} du$$

We can make the integral look more like formula #62 from the Table of Integrals by letting $A^2 = 1 - \frac{x^2}{a^2}$.

$$\begin{aligned} \int_0^{b\sqrt{1-\frac{x^2}{a^2}}} c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}} dy &= \int_0^A bc\sqrt{A^2 - u^2} du \stackrel{\#62}{=} bc \left[\frac{u}{2}\sqrt{A^2 - u^2} + \frac{A^2}{2}\sin^{-1}\left(\frac{u}{A}\right) \right]_0^A \\ &= bc \left[\frac{A}{2}\sqrt{A^2 - A^2} + \frac{A^2}{2}\sin^{-1}\left(\frac{A}{A}\right) - (0 + 0) \right] = \frac{A^2 bc \pi}{4} \\ &= \frac{bc\pi}{4} \left(1 - \frac{x^2}{a^2} \right) \end{aligned}$$

Then

$$\begin{aligned} V &= 8 \int_0^a \int_0^{b\sqrt{1-\frac{x^2}{a^2}}} c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}} dy dx = 8 \left(\frac{bc\pi}{4} \right) \int_0^a \left(1 - \frac{x^2}{a^2} \right) dx = 2bc\pi \left[x - \frac{x^3}{3a^2} \right]_0^a \\ &= 2bc\pi \left(a - \frac{a^3}{3a^2} \right) = \boxed{\frac{4}{3}\pi abc}. \end{aligned}$$

If $a = b = c$, then the volume becomes $V = \frac{4}{3}\pi a^3$, which is the volume of a sphere of radius a .

Challenge Problems

52. The region E is enclosed by the coordinate planes and the parabolic cylinders $a^2y = b(a^2 - x^2)$ and $a^2z = c(a^2 - x^2)$, so $0 \leq z \leq c\left(1 - \frac{x^2}{a^2}\right)$.

The region R in the xy -plane is $0 \leq y \leq b\left(1 - \frac{x^2}{a^2}\right)$, and $0 \leq x \leq a$.

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^a \int_0^{b\left(1 - \frac{x^2}{a^2}\right)} \int_0^{c\left(1 - \frac{x^2}{a^2}\right)} dz \, dy \, dx = \int_0^a \int_0^{b\left(1 - \frac{x^2}{a^2}\right)} [z]_0^{c\left(1 - \frac{x^2}{a^2}\right)} dy \, dx \\
 &= \int_0^a \int_0^{b\left(1 - \frac{x^2}{a^2}\right)} c\left(1 - \frac{x^2}{a^2}\right) dy \, dx = \int_0^a c\left(1 - \frac{x^2}{a^2}\right) [y]_0^{b\left(1 - \frac{x^2}{a^2}\right)} dx = \int_0^a bc\left(1 - \frac{x^2}{a^2}\right)^2 dx \\
 &= \int_0^a bc\left(1 - 2\frac{x^2}{a^2} + \frac{x^4}{a^4}\right) dx = bc\left[x - \frac{2x^3}{3a^2} + \frac{x^5}{5a^4}\right]_0^a = bc\left(a - \frac{2a}{3} + \frac{a}{5}\right) = \boxed{\frac{8}{15}abc}
 \end{aligned}$$

53. We will find the volume in the first octant and then use symmetry to get the total volume. The two parabolic cylinders intersect when $1 - x^2 = 1 - y^2$ or at $y = \pm x$.

We split the region R in the xy -plane into two subregions, R_1 and R_2 .

R_1 is bounded by $0 \leq y \leq x$, $0 \leq x \leq 1$. Since $y \leq x$ in R_1 , $y^2 \leq x^2$. Then $-y^2 \geq -x^2$ and $1 - y^2 \geq 1 - x^2$ which means that $0 \leq z \leq 1 - x^2$ in R_1 .

Similarly, R_2 is bounded by $x \leq y \leq 1$, $0 \leq x \leq 1$. Since $x \leq y$ in R_2 , $x^2 \leq y^2$. Then $-x^2 \geq -y^2$ and $1 - x^2 \geq 1 - y^2$ which means that $0 \leq z \leq 1 - y^2$ in R_2 . The volume in the first octant is

$$\begin{aligned}
 V_1 &= \iiint_E dV = \iiint_{E_1} dV + \iiint_{E_2} dV = \int_0^1 \int_0^x \int_0^{1-x^2} dz dy dx + \int_0^1 \int_x^1 \int_0^{1-y^2} dz dy dx \\
 &= \int_0^1 \int_0^x [z]_0^{1-x^2} dy dx + \int_0^1 \int_x^1 [z]_0^{1-y^2} dy dx = \int_0^1 \int_0^x (1-x^2) dy dx + \int_0^1 \int_x^1 (1-y^2) dy dx \\
 &= \int_0^1 (1-x^2) [y]_0^x dx + \int_0^1 \left[y - \frac{1}{3}y^3 \right]_x^1 dx = \int_0^1 (x-x^3) dx + \int_0^1 \left[\left(1 - \frac{1}{3}\right) - \left(x - \frac{1}{3}x^3\right) \right] dx \\
 &= \int_0^1 (x-x^3) dx + \int_0^1 \left(\frac{2}{3} - x + \frac{1}{3}x^3 \right) dx = \left[\frac{1}{2}x^2 - \frac{1}{4}x^4 \right]_0^1 + \left[\frac{2}{3}x - \frac{1}{2}x^2 + \frac{1}{12}x^4 \right]_0^1 \\
 &= \frac{1}{2} - \frac{1}{4} + \frac{2}{3} - \frac{1}{2} + \frac{1}{12} = \frac{1}{2}.
 \end{aligned}$$

The total volume of the solid is then $V = 4V_1 = 4\left(\frac{1}{2}\right) = \boxed{2}$.

54. (a) In both cases, we are integrating the function over an interval or a region, and then we are dividing the result by the size of that interval or region. Suppose R is a rectangular region bounded by

$a \leq x \leq b$ and $c \leq y \leq d$ and $f(x, y)$ does not depend on y . In this special case, $A = (b-a)(d-c)$ and $f(x, y) = f(x)$.

$$\begin{aligned}\bar{f} &= \frac{1}{A} \iint_R f(x, y) dA = \frac{1}{(b-a)(d-c)} \int_a^b \int_c^d f(x) dy dx = \frac{1}{(b-a)(d-c)} \int_a^b [y]_c^d f(x) dx \\ &= \frac{1}{(b-a)(d-c)} \int_a^b (d-c)f(x) dx = \frac{1}{b-a} \int_a^b f(x) dx\end{aligned}$$

(b) The average value of f over a solid E in space would be the number $\boxed{\frac{1}{V} \iiint_E f(x, y, z) dV}$.

55. (a) The limits of integration here mean that $\frac{x^2+y^2}{4} \leq z \leq 4$, $0 \leq y \leq \sqrt{16-x^2}$, and $0 \leq x \leq 4$. The solid is in the first octant and is bounded below by the paraboloid of revolution $\frac{x^2+y^2}{4}$ and above by the plane $z = 4$. The region R in the xy -plane is enclosed by the quarter of a circle of radius 4 in the first quadrant. In other words, this integral represents the volume over the first quadrant between the paraboloid of revolution and the plane $z = 4$.
- (b) The limits of integration here mean that $0 \leq y \leq \sqrt{4z-x^2}$, $0 \leq x \leq 2\sqrt{z}$, and $0 \leq z \leq 4$. Since $y \leq \sqrt{4z-x^2}$, $y^2 \leq 4z-x^2$ which implies that $z \geq \frac{1}{4}(x^2+y^2)$. This is the same paraboloid of revolution found in part (a). The region R in the xz -plane is enclosed by $x^2 = 4z$, $x = 0$, $z = 0$, and $z = 4$ which is the projection of the paraboloid of revolution onto the xz -plane.
- (c) The limits of integration here mean that $0 \leq x \leq \sqrt{4z-y^2}$, $\frac{y^2}{4} \leq z \leq 4$, and $0 \leq y \leq 4$. Since $x \leq \sqrt{4z-y^2}$, $x^2 \leq 4z-y^2$ which implies that $z \geq \frac{1}{4}(x^2+y^2)$. This is the same paraboloid of revolution found in part (a). The region R in the yz -plane is enclosed by $\frac{y^2}{4} = z$, $y = 0$, $z = 0$, and $z = 4$ which is the projection of the paraboloid of revolution onto the xz -plane.
56. We change the order of integration. From the limits of integration, we know $a \leq x \leq y$, $a \leq y \leq z$, and $a \leq z \leq b$. We can put these inequalities into a single inequality.

$$a \leq x \leq y \leq z \leq b.$$

We choose new limits that satisfy that inequality, noting that we need $a \leq x \leq b$. We see $a \leq x \leq b$, $x \leq y \leq b$, and $y \leq z \leq b$. We can rewrite the integral in a different order with these new limits.

$$\begin{aligned}\int_a^b \int_a^z \int_a^y f(x) dx dy dz &= \int_a^b \int_x^b \int_y^b f(x) dz dy dx = \int_a^b \int_x^b f(x) [z]_y^b dy dx = \int_a^b \int_x^b f(x)(b-y) dy dx \\ &= \int_a^b f(x) \left[\left(by - \frac{1}{2}y^2 \right) \right]_x^b dx = \int_a^b f(x) \left[\left(b^2 - \frac{1}{2}b^2 \right) - \left(bx - \frac{1}{2}x^2 \right) \right] dx \\ &= \int_a^b f(x) \frac{1}{2} (b^2 - 2bx + x^2) dx = \int_a^b f(x) \frac{(b-x)^2}{2} dx = \int_a^b \frac{(b-x)^2}{2} f(x) dx\end{aligned}$$

14.7 Triple Integrals Using Cylindrical Coordinates

Concepts and Vocabulary

1. To convert points in rectangular coordinates to cylindrical coordinates use the equations $x = r \cos \theta$, $y = r \sin \theta$, and $z = z$.
2. According to Table 1, the circular cone $x^2 + y^2 = 4z^2$ has the form $r = 2z$ in cylindrical coordinates.
3. The differential $dV = r dr d\theta dz$.
4. **True**. We know that $\int \int \int_E r dr d\theta dz = \int \int \int_E dV$ which we have seen in previous sections is equal to the volume of E .

Skill Building

5. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{3 + 1} = 2$. Then $\cos \theta = \frac{x}{r} = \frac{-1}{2}$ and $\sin \theta = \frac{y}{r} = \frac{-1}{2}$ so $\theta = \frac{7\pi}{6}$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(2, \frac{7\pi}{6}, -5\right)$.
6. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{1 + 3} = 2$. Then $\cos \theta = \frac{x}{r} = \frac{-1}{2}$ and $\sin \theta = \frac{y}{r} = \frac{\sqrt{3}}{2}$ so $\theta = \frac{5\pi}{6}$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(2, \frac{5\pi}{6}, 4\right)$.
7. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{1 + 1} = \sqrt{2}$. Then $\cos \theta = \frac{x}{r} = \frac{1}{\sqrt{2}}$ and $\sin \theta = \frac{y}{r} = \frac{1}{\sqrt{2}}$ so $\theta = \frac{\pi}{4}$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(\sqrt{2}, \frac{\pi}{4}, \sqrt{2}\right)$.
8. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{4 + 4} = 2\sqrt{2}$. Then $\cos \theta = \frac{x}{r} = \frac{2}{2\sqrt{2}} = \frac{1}{\sqrt{2}}$ and $\sin \theta = \frac{y}{r} = \frac{-2}{2\sqrt{2}} = \frac{-1}{\sqrt{2}}$ so $\theta = \frac{7\pi}{4}$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(2\sqrt{2}, \frac{7\pi}{4}, 4\right)$.
9. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{4 + 0} = 2$. Then $\cos \theta = \frac{x}{r} = \frac{2}{2} = 1$ and $\sin \theta = \frac{y}{r} = \frac{0}{2} = 0$ so $\theta = 0$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = (2, 0, 4)$.
10. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{1 + 0} = 1$. Then $\cos \theta = \frac{x}{r} = \frac{-1}{1} = -1$ and $\sin \theta = \frac{y}{r} = \frac{0}{1} = 0$ so $\theta = \pi$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(1, \pi, \frac{1}{2}\right)$.
11. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{0 + 9} = 3$. Then $\cos \theta = \frac{x}{r} = \frac{0}{3} = 0$ and $\sin \theta = \frac{y}{r} = \frac{3}{3} = 1$ so $\theta = \frac{\pi}{2}$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(3, \frac{\pi}{2}, 4\right)$.

12. In cylindrical coordinates $r = \sqrt{x^2 + y^2} = \sqrt{0 + 1} = 1$. Then $\cos \theta = \frac{x}{r} = \frac{0}{1} = 0$ and $\sin \theta = \frac{y}{r} = \frac{1}{1} = 1$ so $\theta = \frac{\pi}{2}$. Since z remains the same, the point P in cylindrical coordinates is $(r, \theta, z) = \left(1, \frac{\pi}{2}, -3\right)$.

13. We use the equations $x = r \cos \theta$ and $y = r \sin \theta$ with $r = 2$ and $\theta = \frac{\pi}{6}$. Then

$$x = 2 \cos \frac{\pi}{6} = \sqrt{3} \quad y = 2 \sin \frac{\pi}{6} = 1 \quad z = -5$$

In rectangular coordinates, $P = (\sqrt{3}, 1, -5)$.

14. We use the equations $x = r \cos \theta$ and $y = r \sin \theta$ with $r = 4$ and $\theta = \frac{\pi}{3}$. Then

$$x = 4 \cos \frac{\pi}{3} = 2 \quad y = 4 \sin \frac{\pi}{3} = 2\sqrt{3} \quad z = 3$$

In rectangular coordinates, $P = (2, 2\sqrt{3}, 3)$.

15. We use the equations $x = r \cos \theta$ and $y = r \sin \theta$ with $r = 1$ and $\theta = 0$. Then

$$x = 1 \cos 0 = 1 \quad y = 1 \sin 0 = 0 \quad z = 8$$

In rectangular coordinates, $P = (1, 0, 8)$.

16. We use the equations $x = r \cos \theta$ and $y = r \sin \theta$ with $r = 4$ and $\theta = \frac{\pi}{6}$. Then

$$x = 4 \cos \frac{\pi}{6} = 2\sqrt{3} \quad y = 4 \sin \frac{\pi}{6} = 2 \quad z = 2$$

In rectangular coordinates, $P = (2\sqrt{3}, 2, 2)$.

17. We use the equations $x = r \cos \theta$ and $y = r \sin \theta$ with $r = 2$ and $\theta = \frac{\pi}{2}$. Then

$$x = 2 \cos \frac{\pi}{2} = 0 \quad y = 2 \sin \frac{\pi}{2} = 2 \quad z = 0$$

In rectangular coordinates, $P = (0, 2, 0)$.

18. We use the equations $x = r \cos \theta$ and $y = r \sin \theta$ with $r = -3$ and $\theta = \frac{\pi}{2}$. Then

$$x = -3 \cos \frac{\pi}{2} = 0 \quad y = -3 \sin \frac{\pi}{2} = -3 \quad z = 1$$

In rectangular coordinates, $P = (0, -3, 1)$.

19. The solid E of integration and its projection onto the xz -plane can be described by the inequalities

$$0 \leq y \leq \sqrt{1 - x^2 - z^2} \quad -\sqrt{1 - x^2} \leq z \leq \sqrt{1 - x^2} \quad -1 \leq x \leq 1$$

The graph of this solid and its projection onto the xz -plane are given below.

The limits of integration on y are $y = 0$ and $y = \sqrt{1 - x^2 - z^2}$ or, equivalently, $y^2 = 1 - x^2 - z^2$, $y \geq 0$. We can interpret the integral as the volume of a solid E that is a hemisphere of radius 1 situated toward the positive side of the xz -plane, that is $y \geq 0$.

20. The solid E of integration and its projection onto the yz -plane can be described by the inequalities

$$0 \leq x \leq \sqrt{1 - y^2 - z^2} \quad 0 \leq y \leq \sqrt{1 - z^2} \quad 0 \leq z \leq 1$$

The graph of this solid and its projection onto the yz -plane are given below.

The limits of integration on x are $x = 0$ and $x = \sqrt{1 - y^2 - z^2}$ or, equivalently, $x^2 = 1 - y^2 - z^2$, $x \geq 0$. We can interpret the integral as the volume of a solid E that is the portion of a sphere of radius 1 found in the first octant.

21. The solid E of integration and its projection onto the xy -plane can be described by the inequalities

$$0 \leq z \leq \sqrt{x^2 + y^2} \quad -\sqrt{4 - x^2} \leq y \leq \sqrt{4 - x^2} \quad 0 \leq x \leq 2$$

The graph of this solid and its projection onto the xy -plane are given below.

The limits of integration on z are $z = 0$ and $z = \sqrt{x^2 + y^2}$ or, equivalently, $z^2 = x^2 + y^2$, $z \geq 0$. We can see that the volume being computed lies below the cone $z^2 = x^2 + y^2$ and above a portion of the xy -plane. Since $-\sqrt{4-x^2} \leq y \leq \sqrt{4-x^2}$ while $0 \leq x \leq 2$, the volume is being restricted to the vertical cylinder $x^2 + y^2 = 4$, $x \geq 0$ (i.e., a “semicircular” cylinder). So we may interpret the integral as the volume of a solid E that is inside the vertical cylinder $x^2 + y^2 = 4$ with $x \geq 0$ and is bounded below by the xy -plane and bounded above by the cone $z^2 = x^2 + y^2$.

22. The solid E of integration and its projection onto the xz -plane can be described by the inequalities

$$0 \leq y \leq \sqrt{x^2 + z^2} \quad -\sqrt{9-x^2} \leq z \leq \sqrt{9-x^2} \quad 0 \leq x \leq 3$$

The graph of this solid and its projection onto the xz -plane are given below.

The limits of integration on y are $y = 0$ and $y = \sqrt{x^2 + z^2}$ or, equivalently, $y^2 = x^2 + z^2$, $y \geq 0$. We can see that the volume being computed lies between the cone $y^2 = x^2 + z^2$, $y \geq 0$ and the xz -plane. Since $-\sqrt{9 - x^2} \leq z \leq \sqrt{9 - x^2}$ while $0 \leq x \leq 3$, the volume is being restricted to the cylinder $x^2 + z^2 = 9$, $x \geq 0$ (i.e., a “semicircular” cylinder). So we may interpret the integral as the volume of a solid E that is inside the cylinder $x^2 + z^2 = 9$ with $x \geq 0$ and is bounded by the xz -plane and by the cone $y^2 = x^2 + z^2$, $y \geq 0$.

23. The triple integral given is expressed in cylindrical coordinates, so we integrate with respect to the variables as given to obtain

$$\begin{aligned} \int_{\pi/6}^{\pi/2} \int_0^3 \int_0^{r \sin \theta} r \csc^3 \theta \, dz \, dr \, d\theta &= \int_{\pi/6}^{\pi/2} \int_0^3 [r \csc^3 \theta z]_0^{r \sin \theta} \, dr \, d\theta = \int_{\pi/6}^{\pi/2} \int_0^3 [r \csc^3 \theta \cdot r \sin \theta] \, dr \, d\theta \\ &= \int_{\pi/6}^{\pi/2} \int_0^3 r^2 \csc^2 \theta \, dr \, d\theta = \int_{\pi/6}^{\pi/2} \left[\frac{1}{3} r^3 \csc^2 \theta \right]_0^3 \, d\theta = \int_{\pi/6}^{\pi/2} 9 \csc^2 \theta \, d\theta \\ &= [-9 \cot \theta]_{\pi/6}^{\pi/2} = \boxed{9\sqrt{3}} \end{aligned}$$

24. The triple integral given is expressed in cylindrical coordinates, so we integrate with respect to the variables as given to obtain

$$\begin{aligned} \int_{\pi/6}^{\pi/2} \int_0^1 \int_0^{\sin \theta} r \cos \theta \sin \theta \, dz \, dr \, d\theta &= \int_{\pi/6}^{\pi/2} \int_0^1 [r \cos \theta \sin \theta z]_0^{\sin \theta} \, dr \, d\theta = \int_{\pi/6}^{\pi/2} \int_0^1 r \cos \theta \sin^2 \theta \, dr \, d\theta \\ &= \int_{\pi/6}^{\pi/2} \left[\frac{1}{2} r^2 \cos \theta \sin^2 \theta \right]_0^1 \, d\theta = \int_{\pi/6}^{\pi/2} \frac{1}{2} \cos \theta \sin^2 \theta \, d\theta \end{aligned}$$

To evaluate this last integral, we let $u = \sin \theta$ so that $du = \cos \theta d\theta$. Also, $u = \frac{1}{2}$ when $\theta = \frac{\pi}{6}$ and $u = 1$ when $\theta = \frac{\pi}{2}$. We then have

$$\int_{\pi/6}^{\pi/2} \frac{1}{2} \cos \theta \sin^2 \theta d\theta = \int_{1/2}^1 \frac{1}{2} u^2 du = \left[\frac{1}{6} u^3 \right]_{1/2}^1 = \boxed{\frac{7}{48}}$$

25. The triple integral given is expressed in cylindrical coordinates, so we integrate with respect to the variables as given to obtain

$$\begin{aligned} \int_0^{\pi/3} \int_0^1 \int_0^{e^{-1}} r dz dr d\theta &= \int_0^{\pi/3} \int_0^1 [rz]_0^{e^{-1}} dr d\theta = e^{-1} \int_0^{\pi/3} \int_0^1 r dr d\theta \\ &= e^{-1} \int_0^{\pi/3} \left[\frac{1}{2} r^2 \right]_0^1 d\theta = \frac{1}{2e} \int_0^{\pi/3} d\theta = \boxed{\frac{\pi}{6e}} \end{aligned}$$

26. The triple integral given is expressed in cylindrical coordinates, so we integrate with respect to the variables as given to obtain

$$\begin{aligned} \int_0^{\pi/3} \int_0^{\sin \theta} \int_0^{r \sin \theta} r dz dr d\theta &= \int_0^{\pi/3} \int_0^{\sin \theta} [rz]_0^{r \sin \theta} dr d\theta = \int_0^{\pi/3} \int_0^{\sin \theta} r^2 \sin \theta dr d\theta \\ &= \int_0^{\pi/3} \left[\frac{1}{3} r^3 \sin \theta \right]_0^{\sin \theta} d\theta = \int_0^{\pi/3} \frac{1}{3} \sin^4 \theta d\theta = \int_0^{\pi/3} \frac{1}{3} (\sin^2 \theta)^2 d\theta \\ &= \int_0^{\pi/3} \frac{1}{12} (1 - 2 \cos(2\theta) + \cos^2(2\theta)) d\theta \\ &= \int_0^{\pi/3} \frac{1}{12} \left(1 - 2 \cos(2\theta) + \frac{1}{2} (1 + \cos(4\theta)) \right) d\theta \\ &= \int_0^{\pi/3} \frac{1}{24} (3 - 4 \cos(2\theta) + \cos(4\theta)) d\theta = \frac{1}{24} \left[3\theta - 2 \sin(2\theta) + \frac{1}{4} \sin(4\theta) \right]_0^{\pi/3} \\ &= \frac{1}{24} \left[\pi - \sqrt{3} - \frac{\sqrt{3}}{8} \right] = \boxed{\frac{\pi}{24} - \frac{3\sqrt{3}}{64}} \end{aligned}$$

27. We see that $1 \leq z \leq 4$, so we will integrate with respect to z first. The projection onto the xy -plane is the region bounded by the circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 9$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $1 \leq z \leq 4$, $1 \leq r \leq 3$, and $0 \leq \theta \leq 2\pi$. We compute

$$\begin{aligned} \iiint_E dV &= \int_0^{2\pi} \int_1^3 \int_1^4 r dz dr d\theta = \int_0^{2\pi} \int_1^3 [rz]_1^4 dr d\theta = \int_0^{2\pi} \int_1^3 3r dr d\theta \\ &= \int_0^{2\pi} \left[\frac{3}{2} r^2 \right]_1^3 d\theta = \int_0^{2\pi} 12 d\theta = \boxed{24\pi} \end{aligned}$$

28. We see that $0 \leq z \leq 3$, so we will integrate with respect to z first. The projection onto the xy -plane is the region bounded by the circle $x^2 + y^2 = 4$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $0 \leq z \leq 3$, $0 \leq r \leq 2$, and $0 \leq \theta \leq 2\pi$. We compute

$$\begin{aligned} \iiint_E dV &= \int_0^{2\pi} \int_0^2 \int_0^3 r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^2 [rz]_0^3 \, dr \, d\theta = \int_0^{2\pi} \int_0^2 3r \, dr \, d\theta \\ &= \int_0^{2\pi} \left[\frac{3}{2} r^2 \right]_0^2 \, d\theta = \int_0^{2\pi} 6 \, d\theta = \boxed{12\pi} \end{aligned}$$

29. We see that the z -coordinate lies between $z = 1$ and $z = x + 3$ and, because the smallest value of x in this solid is $x = -2$, we see that $1 \leq z \leq x + 3$.

We will integrate with respect to z first. The projection onto the xy -plane is the region bounded by the circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 4$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $1 \leq z \leq r \cos \theta + 3$, $1 \leq r \leq 2$, and $0 \leq \theta \leq 2\pi$. We compute

$$\begin{aligned} \int \int \int_E y \, dV &= \int_0^{2\pi} \int_1^2 \int_1^{r \cos \theta + 3} r \sin \theta \cdot r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_1^2 [r^2 \sin \theta z]_1^{r \cos \theta + 3} \, dr \, d\theta \\ &= \int_0^{2\pi} \int_1^2 (r^3 \sin \theta \cos \theta + 3r^2 \sin \theta) \, dr \, d\theta = \int_0^{2\pi} \left[\frac{r^4}{4} \sin \theta \cos \theta + r^3 \sin \theta \right]_1^2 \, d\theta \\ &= \int_0^{2\pi} \left(\frac{15}{4} \sin \theta \cos \theta + 7 \sin \theta \right) \, d\theta = \left[\frac{15}{8} \sin^2 \theta - 7 \cos \theta \right]_0^{2\pi} = \boxed{0} \end{aligned}$$

30. We see that the solid can be broken into two solids S_1 where $x \leq z \leq 0$ for $x \leq 0$ and S_2 where $0 \leq z \leq x$ for $x \geq 0$.

We will set up a triple integral for S_1 and S_2 integrating with respect to z first in each case. That is,

$$\int \int \int_E x \, dV = \int \int \int_{S_1} x \, dV + \int \int \int_{S_2} x \, dV$$

For S_1 , the projection onto the xy -plane is the region bounded by the semicircle $x^2 + y^2 = 9$ where $x \leq 0$ and $y = 0$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $r \cos \theta \leq z \leq 0$, $0 \leq r \leq 3$, and $\frac{\pi}{2} \leq \theta \leq \frac{3\pi}{2}$. We compute

$$\begin{aligned}
\int \int \int_{S_1} x \, dV &= \int_{\pi/2}^{3\pi/2} \int_0^3 \int_{r \cos \theta}^0 r \cos \theta \cdot r \, dz \, dr \, d\theta = \int_{\pi/2}^{3\pi/2} \int_0^3 [r^2 \cos \theta z]_{r \cos \theta}^0 \, dr \, d\theta \\
&= - \int_{\pi/2}^{3\pi/2} \int_0^3 (r^3 \cos^2 \theta) \, dr \, d\theta = - \int_{\pi/2}^{3\pi/2} \left[\frac{r^4}{4} \cos^2 \theta \right]_0^3 \, d\theta \\
&= - \int_{\pi/2}^{3\pi/2} \left(\frac{81}{4} \cos^2 \theta \right) \, d\theta = - \int_{\pi/2}^{3\pi/2} \left(\frac{81}{8} (1 + \cos(2\theta)) \right) \, d\theta \\
&= - \frac{81}{8} \left[\theta + \frac{1}{2} \sin(2\theta) \right]_{\pi/2}^{3\pi/2} = - \frac{81}{8} \pi
\end{aligned}$$

For S_2 , the projection onto the xy -plane is the region bounded by the semicircle $x^2 + y^2 = 9$ where $x \geq 0$ and $y = 0$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $0 \leq z \leq r \cos \theta$, $0 \leq r \leq 3$, and $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. We compute

$$\begin{aligned}
\int \int \int_{S_2} x \, dV &= \int_{-\pi/2}^{\pi/2} \int_0^3 \int_0^{r \cos \theta} r \cos \theta \cdot r \, dz \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} \int_0^3 [r^2 \cos \theta z]_0^{r \cos \theta} \, dr \, d\theta \\
&= \int_{-\pi/2}^{\pi/2} \int_0^3 (r^3 \cos^2 \theta) \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} \left[\frac{r^4}{4} \cos^2 \theta \right]_0^3 \, d\theta \\
&= \int_{-\pi/2}^{\pi/2} \left(\frac{81}{4} \cos^2 \theta \right) \, d\theta = \int_{-\pi/2}^{\pi/2} \left(\frac{81}{8} (1 + \cos(2\theta)) \right) \, d\theta \\
&= \frac{81}{8} \left[\theta + \frac{1}{2} \sin(2\theta) \right]_{-\pi/2}^{\pi/2} = \frac{81}{8} \pi
\end{aligned}$$

We have

$$\int \int \int_E x \, dV = \boxed{0}$$

31. We see that the z -coordinate lies between $z = 1 - x - y$ and $z = 3 - x - y$, so we will integrate with respect to z first.

The projection onto the xy -plane is the region bounded by the circle $x^2 + y^2 = 1$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $1 - r \cos \theta - r \sin \theta \leq z \leq 3 - r \cos \theta - r \sin \theta$, $0 \leq r \leq 1$, and $0 \leq \theta \leq 2\pi$. We compute

$$\begin{aligned}
 \iiint_E xy \, dV &= \int_0^{2\pi} \int_0^1 \int_{1-r \cos \theta - r \sin \theta}^{3-r \cos \theta - r \sin \theta} r \cos \theta \cdot r \sin \theta \cdot r \, dz \, dr \, d\theta \\
 &= \int_0^{2\pi} \int_0^1 [r^3 \sin \theta \cos \theta z]_{1-r \cos \theta - r \sin \theta}^{3-r \cos \theta - r \sin \theta} \, dr \, d\theta = \int_0^{2\pi} \int_0^1 (2r^3 \sin \theta \cos \theta) \, dr \, d\theta \\
 &= \int_0^{2\pi} \int_0^1 (r^3 \sin(2\theta)) \, dr \, d\theta = \int_0^{2\pi} \left[\frac{r^4}{4} \sin(2\theta) \right]_0^1 \, d\theta \\
 &= \int_0^{2\pi} \frac{1}{4} \sin(2\theta) \, d\theta = \left[-\frac{1}{8} \cos(2\theta) \right]_0^{2\pi} = \boxed{0}
 \end{aligned}$$

32. We see that the z -coordinate lies between $z = 0$ and $z = x^2 + y^2$, so we will integrate with respect to z first. The projection onto the xy -plane is the region bounded by the circle $x^2 + y^2 = 4$ as shown in the figure.

We use cylindrical coordinates to describe the solid of integration: $0 \leq z \leq x^2 + y^2$, $0 \leq r \leq 2$, and $0 \leq \theta \leq 2\pi$. We compute

$$\begin{aligned} \int \int \int_E xy \, dV &= \int_0^{2\pi} \int_0^2 \int_0^{r^2} r \cos \theta \cdot r \sin \theta \cdot r \, dz dr d\theta = \int_0^{2\pi} \int_0^2 [r^3 \sin \theta \cos \theta z]_0^{r^2} dr d\theta \\ &= \int_0^{2\pi} \int_0^2 r^5 \sin \theta \cos \theta \, dr d\theta = \int_0^{2\pi} \left[\frac{r^6}{6} \sin \theta \cos \theta \right]_0^2 d\theta \\ &= \int_0^{2\pi} \frac{32}{3} \sin \theta \cos \theta \, d\theta = \left[\frac{16}{3} \sin^2 \theta \right]_0^{2\pi} = \boxed{0} \end{aligned}$$

Applications and Extensions

33. We are seeking the volume of the solid that lies inside the given cylinder and the given sphere simultaneously (see figure).

The solid E whose volume we seek lies beneath the surface $x^2 + y^2 + z^2 = 9$ over the region $x^2 + y^2 = 2$. Because $x^2 + y^2$ appears in both the sphere and the cylinder, we use cylindrical coordinates. The rectangular equation $x^2 + y^2 + z^2 = 9$ becomes $r^2 + z^2 = 9$ in cylindrical coordinates. That is, $-\sqrt{9 - r^2} \leq z \leq \sqrt{9 - r^2}$. In cylindrical coordinates, the rectangular region bounded by $x^2 + y^2 = 2$

in the xy -plane may be described by $0 \leq r \leq \sqrt{2}$ where $0 \leq \theta \leq 2\pi$. The volume V of the solid is

$$\begin{aligned} V &= \int \int \int_E dV = \int \int \int_E r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} \int_{-\sqrt{9-r^2}}^{\sqrt{9-r^2}} r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} [rz]_{-\sqrt{9-r^2}}^{\sqrt{9-r^2}} \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^{\sqrt{2}} 2r\sqrt{9-r^2} \, dr \, d\theta = \int_0^{\sqrt{2}} 2r\sqrt{9-r^2} \, dr \int_0^{2\pi} d\theta = \left[-(9-r^2)^{3/2} \cdot \frac{2}{3} \right]_0^{\sqrt{2}} (2\pi) \\ &= -\frac{4\pi}{3} [7^{3/2} - 9^{3/2}] = -\frac{4\pi}{3} (7\sqrt{7} - 27) = 4\pi \left(9 - \frac{7\sqrt{7}}{3} \right) \end{aligned}$$

The volume is $\boxed{4\pi \left(9 - \frac{7\sqrt{7}}{3} \right) \text{ cubic units}}.$

34. We see that for $z \geq 0$, this solid is identical to the solid discussed in Example 3. Therefore the volume of this portion of the solid is $\frac{8\pi}{3} - \frac{32}{9}$ cubic units. By symmetry, the total volume of the solid described

in this problem is $\boxed{2 \left(\frac{8\pi}{3} - \frac{32}{9} \right) = \frac{16\pi}{3} - \frac{64}{9} \text{ cubic units}}.$

35. We are seeking the volume of the solid that lies inside the given paraboloids of revolution simultaneously (see figure).

The solid E whose volume we seek lies beneath the surface $z = 16 - x^2 - y^2$ and above the surface $z = x^2 + y^2$. To find the projection of this solid onto the xy -plane, we find the intersection of the two surfaces. That is, we set $16 - x^2 - y^2 = x^2 + y^2$ to obtain $x^2 + y^2 = 8$. Because $x^2 + y^2$ that appears throughout these expressions, we use cylindrical coordinates. The rectangular equation $z = 16 - x^2 - y^2$ becomes $z = 16 - r^2$, $z = x^2 + y^2$ becomes $z = r^2$, and $x^2 + y^2 = 8$ may be described by $0 \leq r \leq 2\sqrt{2}$ where $0 \leq \theta \leq 2\pi$. The volume V of the solid is

$$\begin{aligned} V &= \int \int \int_E dV = \int \int \int_E r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^{2\sqrt{2}} \int_{r^2}^{16-r^2} r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^{2\sqrt{2}} [rz]_{r^2}^{16-r^2} \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^{2\sqrt{2}} (16r - 2r^3) \, dr \, d\theta = \int_0^{2\sqrt{2}} (16r - 2r^3) \, dr \int_0^{2\pi} d\theta = \left[8r^2 - \frac{2}{4}r^4 \right]_0^{2\sqrt{2}} (2\pi) \\ &= (32)(2\pi) = 64\pi \end{aligned}$$

The volume is $\boxed{64\pi \text{ cubic units}}$.

36. We are seeking the volume of the solid that lies inside the given paraboloid of revolution and under the given plane simultaneously (see figure).

The solid E whose volume we seek lies beneath the surface $z = 2 - x$ and above the surface $z = x^2 + y^2$. To find the projection of this solid onto the xy plane, we find the intersection of the two surfaces. That is, we set $2 - x = x^2 + y^2$ to obtain $x^2 + x + y^2 = 2$. Completing the square, we may write $\left(x + \frac{1}{2}\right)^2 + y^2 = \frac{9}{4}$, so that we see that the projection onto the xy -plane is a region bounded by a circle.

This region in the plane is not well described by polar coordinates, so we will use rectangular coordinates to find this volume. The volume of the solid is

$$\begin{aligned} V &= \int \int \int_E dV = \int_{-2}^1 \int_{-\sqrt{9/4-(x+1/2)^2}}^{\sqrt{9/4-(x+1/2)^2}} \int_{x^2+y^2}^{2-x} dz dy dx = \int_{-2}^1 \int_{-\sqrt{9/4-(x+1/2)^2}}^{\sqrt{9/4-(x+1/2)^2}} (2-x-x^2-y^2) dy dx \\ &= \int_{-2}^1 \left[2y - xy - x^2y - \frac{1}{3}y^3 \right]_{-\sqrt{9/4-(x+1/2)^2}}^{\sqrt{9/4-(x+1/2)^2}} dx \\ &= \int_{-2}^1 -2\sqrt{9/4-(x+1/2)^2} \left(x - \frac{1}{3} \left(x + \frac{1}{2} \right)^2 + x^2 - \frac{5}{4} \right) dx = \int_{-2}^1 \frac{4}{3} \left(\frac{9}{4} - \left(x + \frac{1}{2} \right)^2 \right)^{3/2} dx \end{aligned}$$

We now make the substitution $\frac{3}{2} \sin \theta = x + \frac{1}{2}$ so that $\frac{3}{2} \cos \theta d\theta = dx$ and $\theta = -\frac{\pi}{2}$ when $x = -2$ and $\theta = \frac{\pi}{2}$ when $x = 1$. We may compute

$$\begin{aligned}
\int_{-2}^1 \frac{4}{3} \left(\frac{9}{4} - \left(x + \frac{1}{2} \right)^2 \right)^{3/2} dx &= \frac{4}{3} \int_{-\pi/2}^{\pi/2} \left(\frac{9}{4} - \frac{9}{4} \sin^2 \theta \right)^{3/2} \frac{3}{2} \cos \theta d\theta = \frac{27}{4} \int_{-\pi/2}^{\pi/2} \cos^4 \theta d\theta \\
&= \frac{27}{4} \int_{-\pi/2}^{\pi/2} (\cos^2 \theta)^2 d\theta = \frac{27}{4} \int_{-\pi/2}^{\pi/2} \left(\frac{1}{2} (1 + \cos(2\theta)) \right)^2 d\theta \\
&= \frac{27}{16} \int_{-\pi/2}^{\pi/2} (1 + 2\cos(2\theta) + \cos^2(2\theta)) d\theta \\
&= \frac{27}{16} \int_{-\pi/2}^{\pi/2} \left(1 + 2\cos(2\theta) + \frac{1}{2}(1 + \cos(4\theta)) \right) d\theta \\
&= \frac{27}{16} \int_{-\pi/2}^{\pi/2} \left(\frac{3}{2} + 2\cos(2\theta) + \frac{1}{2}\cos(4\theta) \right) d\theta \\
&= \frac{27}{16} \left[\frac{3}{2}\theta + \sin(2\theta) + \frac{1}{8}\sin(4\theta) \right]_{-\pi/2}^{\pi/2} = \frac{27}{16} \left[\frac{3}{2} \cdot \frac{\pi}{2} - \frac{3}{2} \left(-\frac{\pi}{2} \right) \right] \\
&= \frac{81\pi}{32}
\end{aligned}$$

The volume is $\boxed{\frac{81\pi}{32} \text{ cubic units}}.$

37. We are seeking the volume of the solid that lies inside the cylinder $x^2 + y^2 = 2x$ and inside $z^2 = 4x$ simultaneously (see figure).

By symmetry, we will find the volume between $z = 0$ and $z^2 = 4x, z \geq 0$ over the region in the xy -plane bounded by $x^2 + y^2 = 2x$ and double it. As was shown in Example 3, $x^2 + y^2 = 2x$ can be written as $r = 2 \cos \theta$ in cylindrical coordinates while $z = \sqrt{4x} = 2\sqrt{r \cos \theta}$. This solid may be described by

$0 \leq z \leq 2\sqrt{r \cos \theta}$, $0 \leq r \leq 2 \cos \theta$, and $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. The total volume V of the original solid is

$$\begin{aligned} V &= \int \int \int_E dV = \int \int \int_E r \, dz \, dr \, d\theta = 2 \int_{-\pi/2}^{\pi/2} \int_0^{2 \cos \theta} \int_0^{2\sqrt{r \cos \theta}} r \, dz \, dr \, d\theta \\ &= 2 \int_{-\pi/2}^{\pi/2} \int_0^{2 \cos \theta} [rz]_0^{2\sqrt{r \cos \theta}} \, dr \, d\theta = 4 \int_{-\pi/2}^{\pi/2} \int_0^{2 \cos \theta} r^{3/2} \cos^{1/2} \theta \, dr \, d\theta \\ &= 4 \int_{-\pi/2}^{\pi/2} \left[\frac{2}{5} r^{5/2} \cos^{1/2} \theta \right]_0^{2 \cos \theta} d\theta = \frac{8}{5} \int_{-\pi/2}^{\pi/2} \left(2^{5/2} \cos^{5/2} \theta \cos^{1/2} \theta \right) d\theta = \frac{32\sqrt{2}}{5} \int_{-\pi/2}^{\pi/2} \cos^3 \theta \, d\theta \\ &= \frac{32\sqrt{2}}{5} \int_{-\pi/2}^{\pi/2} \cos \theta (1 - \sin^2 \theta) \, d\theta = \frac{32\sqrt{2}}{5} \left[\sin \theta - \frac{1}{3} \sin^3 \theta \right]_{-\pi/2}^{\pi/2} = \frac{32\sqrt{2}}{5} \left[\frac{4}{3} \right] = \frac{128\sqrt{2}}{15} \end{aligned}$$

The volume is $\boxed{\frac{128\sqrt{2}}{15} \text{ cubic units}}.$

38. Since ρ is constant and the solid E is a sphere of radius a , the mass M of the solid is

$$M = \int \int \int_E \rho \, dV = \rho \int \int \int_E dV = \rho \frac{4}{3} \pi a^3 = \frac{4\rho\pi a^3}{3}$$

The mass is $\boxed{\frac{4\rho\pi a^3}{3}}.$

39. We will center the sphere at the origin so that its equation is $x^2 + y^2 + z^2 = a^2$. Then the density at each point (x, y, z) in this solid is given by $\rho(x, y, z) = k(x^2 + y^2 + z^2)$ where k is the constant of proportionality. Using cylindrical coordinates, the sphere can be expressed as $r^2 + z^2 = a^2$, so that the solid E whose mass we seek is $-\sqrt{a^2 - r^2} \leq z \leq \sqrt{a^2 - r^2}$, $0 \leq r \leq a$, and $0 \leq \theta \leq 2\pi$. By symmetry, we can double the mass of the upper hemisphere of this solid to obtain the total mass. The total mass M of the solid is

$$\begin{aligned} M &= \int \int \int_E \rho(x, y, z) \, dV = 2k \int_0^{2\pi} \int_0^a \int_0^{\sqrt{a^2 - r^2}} (r^2 + z^2) r \, dz \, dr \, d\theta \\ &= 2k \int_0^{2\pi} \int_0^a \left[r^3 z + \frac{1}{3} r z^3 \right]_0^{\sqrt{a^2 - r^2}} \, dr \, d\theta = 2k \int_0^{2\pi} \int_0^a \left(r^3 \sqrt{a^2 - r^2} + \frac{1}{3} r (\sqrt{a^2 - r^2})^3 \right) \, dr \, d\theta \\ &= 2k \int_0^{2\pi} d\theta \frac{1}{3} \int_0^a \left(3r^3 \sqrt{a^2 - r^2} + r (\sqrt{a^2 - r^2})^3 \right) \, dr \end{aligned}$$

The first of these integrals is 2π . To evaluate the second integral, we use the substitution $u = a^2 - r^2$ with $du = -2r \, dr$. We see that $u = a^2$ when $r = 0$, $u = 0$ when $r = a$, and $r^2 = a^2 - u$.

$$\begin{aligned} \frac{1}{3} \int_0^a \left(3r^3 \sqrt{a^2 - r^2} + r (\sqrt{a^2 - r^2})^3 \right) \, dr &= -\frac{1}{6} \int_0^a \left(3r^2 (-2r) \sqrt{a^2 - r^2} + (-2r) (\sqrt{a^2 - r^2})^3 \right) \, dr \\ &= -\frac{1}{6} \int_{a^2}^0 \left(3(a^2 - u) \sqrt{u} + (\sqrt{u})^3 \right) \, du = \frac{1}{6} \int_0^{a^2} \left(3(a^2 - u) u^{1/2} + u^{3/2} \right) \, du \\ &= \frac{1}{6} \int_0^{a^2} \left(3a^2 u^{1/2} - 2u^{3/2} \right) \, du = \frac{1}{6} \left[2a^2 u^{3/2} - \frac{4}{5} u^{5/2} \right]_0^{a^2} = \frac{1}{6} \left(2a^5 - \frac{4}{5} a^5 \right) = \frac{a^5}{5} \end{aligned}$$

So we have the total mass of the solid given by

$$M = 2k \int_0^{2\pi} d\theta \frac{1}{3} \int_0^a \left(3r^3 \sqrt{a^2 - r^2} + r (\sqrt{a^2 - r^2})^3 \right) \, dr = 2k(2\pi) \frac{a^5}{5} = \frac{4k\pi a^5}{5}$$

The mass is $\boxed{\frac{4k\pi a^5}{5}}$.

40. We will position the cylinder with its base on the xy plane centered at the origin, so that the cylinder E has equation $x^2 + y^2 = a^2$ with $0 \leq z \leq h$. Then the density at each point (x, y, z) in this solid is given by $\rho(x, y, z) = k(x^2 + y^2)$ where k is the constant of proportionality. Using cylindrical coordinates, the solid can be expressed as $0 \leq z \leq h$, $0 \leq r \leq a$, and $0 \leq \theta \leq 2\pi$. The mass M of the solid is

$$\begin{aligned} M &= \int \int \int_E \rho(x, y, z) \, dV = \int_0^{2\pi} \int_0^a \int_0^h kr^2 \cdot r \, dzdrd\theta = k \int_0^{2\pi} \int_0^a \int_0^h r^3 \, dzdrd\theta \\ &= k \int_0^{2\pi} \int_0^a [r^3 z]_0^h \, drd\theta = kh \int_0^{2\pi} \int_0^a r^3 \, drd\theta = kh \int_0^{2\pi} \left[\frac{1}{4} r^4 \right]_0^a \, d\theta = \frac{kha^4}{4} \int_0^{2\pi} d\theta = \frac{kha^4\pi}{2} \end{aligned}$$

The mass of the solid is $\boxed{\frac{kha^4\pi}{2}}$

41. The projection of the hemisphere onto the xy plane is the region bounded by $x^2 + y^2 = 9$. The solid E can be described in polar coordinates as $0 \leq z \leq \sqrt{9 - r^2}$, $0 \leq r \leq 3$, and $0 \leq \theta \leq 2\pi$. We are given $\rho(x, y, z) = kz$ where k is the constant of proportionality. We will compute the moment of inertia about the z -axis and then use the fact that $I_x = \frac{1}{2}I_z$ to find the moment of inertia about the x -axis. The moment of inertia about the z -axis is

$$\begin{aligned} I_z &= \int \int \int_E (\sqrt{x^2 + y^2})^2 \rho(x, y, z) \, dV = \int_0^{2\pi} \int_0^3 \int_0^{\sqrt{9-r^2}} r^2 kz \cdot r \, dzdrd\theta \\ &= k \int_0^{2\pi} \int_0^3 \int_0^{\sqrt{9-r^2}} r^3 z \, dzdrd\theta = k \int_0^{2\pi} \int_0^3 \left[\frac{1}{2} r^3 z^2 \right]_0^{\sqrt{9-r^2}} \, drd\theta = \frac{k}{2} \int_0^{2\pi} \int_0^3 (9r^3 - r^5) \, drd\theta \\ &= \frac{k}{2} \int_0^{2\pi} \left[\frac{9}{4} r^4 - \frac{1}{6} r^6 \right]_0^3 \, d\theta = \frac{k}{2} \int_0^{2\pi} \frac{243}{4} \, d\theta = \frac{243k}{8} \int_0^{2\pi} d\theta = \frac{243k\pi}{4} \end{aligned}$$

We see that $I_x = \frac{1}{2}I_z = \frac{243k\pi}{8}$. By symmetry the moment of inertia about x -axis and the moment of

inertia about the y -axis are equal. That is, $\boxed{I_y = I_x = \frac{243k\pi}{8}}$.

42. Using cylindrical coordinates we have $xy = r^2 \cos \theta \sin \theta$, so the solid E is given by $0 \leq z \leq r^2 \cos \theta \sin \theta$, $0 \leq r \leq 2$, and $0 \leq \theta \leq \frac{\pi}{2}$. Using ρ to represent the density, the mass M of E is

$$\begin{aligned} M &= \int \int \int_E \rho \, dV = \rho \int_0^{\pi/2} \int_0^2 \int_0^{r^2 \cos \theta \sin \theta} r \, dzdrd\theta = \rho \int_0^{\pi/2} \int_0^2 [rz]_0^{r^2 \cos \theta \sin \theta} \, drd\theta \\ &= \rho \int_0^{\pi/2} \int_0^2 r^3 \cos \theta \sin \theta \, drd\theta = \rho \int_0^{\pi/2} \left[\frac{1}{4} r^4 \cos \theta \sin \theta \right]_0^2 \, d\theta = \rho \int_0^{\pi/2} 4 \cos \theta \sin \theta \, d\theta \\ &= 4\rho \left[\frac{1}{2} \sin^2 \theta \right]_0^{\pi/2} = 2\rho \end{aligned}$$

We now compute M_{yz}

$$\begin{aligned} M_{yz} &= \int \int \int_E x \rho \, dV = \rho \int_0^{\pi/2} \int_0^2 \int_0^{r^2 \cos \theta \sin \theta} r^2 \cos \theta \, dz \, dr \, d\theta = \rho \int_0^{\pi/2} \int_0^2 [r^2 \cos \theta z]_0^{r^2 \cos \theta \sin \theta} \, dr \, d\theta \\ &= \rho \int_0^{\pi/2} \int_0^2 r^4 \cos^2 \theta \sin \theta \, dr \, d\theta = \rho \int_0^{\pi/2} \left[\frac{1}{5} r^5 \cos^2 \theta \sin \theta \right]_0^2 \, d\theta = \frac{32\rho}{5} \int_0^{\pi/2} \cos^2 \theta \sin \theta \, d\theta \\ &= \frac{32\rho}{5} \left[-\frac{1}{3} \cos^3 \theta \right]_0^{\pi/2} = \frac{32\rho}{15} \end{aligned}$$

We see that x and y are interchangeable throughout this problem. This symmetry allows us to conclude that $M_{xz} = \frac{32\rho}{15}$.

We now compute M_{xy} .

$$\begin{aligned} M_{xy} &= \int \int \int_E z \rho \, dV = \rho \int_0^{\pi/2} \int_0^2 \int_0^{r^2 \cos \theta \sin \theta} r z \, dz \, dr \, d\theta = \rho \int_0^{\pi/2} \int_0^2 \left[\frac{1}{2} r z^2 \right]_0^{r^2 \cos \theta \sin \theta} \, dr \, d\theta \\ &= \frac{\rho}{2} \int_0^{\pi/2} \int_0^2 r^5 \cos^2 \theta \sin^2 \theta \, dr \, d\theta = \frac{\rho}{2} \int_0^{\pi/2} \left[\frac{1}{6} r^6 \cos^2 \theta \sin^2 \theta \right]_0^2 \, d\theta = \frac{16\rho}{3} \int_0^{\pi/2} \cos^2 \theta \sin^2 \theta \, d\theta \\ &= \frac{16\rho}{3} \int_0^{\pi/2} \frac{1}{2} (1 + \cos(2\theta)) \frac{1}{2} (1 - \cos(2\theta)) \, d\theta = \frac{4\rho}{3} \int_0^{\pi/2} (1 - \cos^2(2\theta)) \, d\theta \\ &= \frac{4\rho}{3} \int_0^{\pi/2} \left(1 - \frac{1}{2} (1 + \cos(4\theta)) \right) \, d\theta = \frac{4\rho}{3} \int_0^{\pi/2} \left(\frac{1}{2} - \frac{1}{2} \cos(4\theta) \right) \, d\theta = \frac{2\rho}{3} \left[\theta - \frac{1}{4} \sin(4\theta) \right]_0^{\pi/2} \\ &= \frac{\pi\rho}{3} \end{aligned}$$

We may now compute

$$\bar{x} = \frac{M_{yz}}{M} = \frac{\frac{32\rho}{15}}{\frac{32\rho}{15}} = \frac{16}{15} \quad \bar{y} = \frac{M_{xz}}{M} = \frac{\frac{32\rho}{15}}{\frac{32\rho}{15}} = \frac{16}{15} \quad \bar{z} = \frac{M_{xy}}{M} = \frac{\frac{\pi\rho}{3}}{\frac{32\rho}{15}} = \frac{\pi}{6}$$

The center of mass is $\left(\bar{x}, \bar{y}, \bar{z} \right) = \left(\frac{16}{15}, \frac{16}{15}, \frac{\pi}{6} \right)$.

43. Because the z -axis is a line of symmetry for the solid, we know that the center of mass must lie on the z -axis. That is $\bar{x} = 0$ and $\bar{y} = 0$. The projection of the solid E onto the xy -plane is bounded by $x^2 + y^2 = 8$. Using cylindrical coordinates we have $\frac{1}{4}(x^2 + y^2) = \frac{1}{4}r^2$, so the solid is given by $\frac{1}{4}r^2 \leq z \leq 2$, $0 \leq r \leq 2\sqrt{2}$, and $0 \leq \theta \leq 2\pi$. Using ρ to represent the density, the mass M of E is

$$\begin{aligned} M &= \int \int \int_E \rho \, dV = \rho \int_0^{2\pi} \int_0^{2\sqrt{2}} \int_{\frac{1}{4}r^2}^2 r \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^{2\sqrt{2}} [rz]_{\frac{1}{4}r^2}^2 \, dr \, d\theta \\ &= \rho \int_0^{2\pi} \int_0^{2\sqrt{2}} \left(2r - \frac{1}{4}r^3 \right) \, dr \, d\theta = \frac{\rho}{4} \int_0^{2\pi} \int_0^{2\sqrt{2}} (8r - r^3) \, dr \, d\theta = \frac{\rho}{4} \int_0^{2\pi} \left[4r^2 - \frac{1}{4}r^4 \right]_0^{2\sqrt{2}} \, d\theta \\ &= \frac{\rho}{4} \int_0^{2\pi} 16 \, d\theta = 8\rho\pi \end{aligned}$$

We now compute M_{xy} .

$$\begin{aligned}
 M_{xy} &= \int \int_E z \rho \, dV = \rho \int_0^{2\pi} \int_0^{2\sqrt{2}} \int_{\frac{1}{4}r^2}^2 rz \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^{2\sqrt{2}} \left[\frac{1}{2} r z^2 \right]_{\frac{1}{4}r^2}^2 dr \, d\theta \\
 &= \rho \int_0^{2\pi} \int_0^{2\sqrt{2}} \left(2r - \frac{1}{32} r^5 \right) dr \, d\theta = \frac{\rho}{32} \int_0^{2\pi} \int_0^{2\sqrt{2}} (64r - r^5) dr \, d\theta = \frac{\rho}{32} \int_0^{2\pi} \left[32r^2 - \frac{1}{6} r^6 \right]_0^{2\sqrt{2}} d\theta \\
 &= \frac{\rho}{32} \int_0^{2\pi} \frac{512}{3} d\theta = \frac{32\rho\pi}{3}
 \end{aligned}$$

We may now compute

$$\bar{z} = \frac{M_{xy}}{M} = \frac{\frac{32\rho\pi}{3}}{8\rho\pi} = \frac{4}{3}$$

The center of mass is $\boxed{(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{4}{3}\right)}$.

44. Because the z -axis is a line of symmetry for the solid, we know that the center of mass must lie on the z -axis. That is $\bar{x} = 0$ and $\bar{y} = 0$. The projection of the solid E onto the xy -plane is found by finding the intersection of the surfaces $z = x^2 + y^2$ and $x^2 + y^2 + z^2 = 12$. Substituting $z = x^2 + y^2$ into $x^2 + y^2 + z^2 = 12$, we obtain $z + z^2 = 12$ which means $z^2 + z - 12 = 0$ or $(z + 4)(z - 3) = 0$. We see that this implies $z = -4$ or $z = 3$, but we must have $z \geq 0$ since $z = x^2 + y^2$, so $z = 3$. Substituting $z = 3$ into $z = x^2 + y^2$ we get the curve of intersection to be $x^2 + y^2 = 3$, which is the bounding curve for the projection of E onto the xy -plane. Using cylindrical coordinates $x^2 + y^2 = r^2$ and $\sqrt{12 - x^2 - y^2} = \sqrt{12 - r^2}$, so the solid is given by $r^2 \leq z \leq \sqrt{12 - r^2}$, $0 \leq r \leq \sqrt{3}$, and $0 \leq \theta \leq 2\pi$. Using ρ to represent the density, the mass M of E is

$$\begin{aligned}
 M &= \int \int_E \rho \, dV = \rho \int_0^{2\pi} \int_0^{\sqrt{3}} \int_{r^2}^{\sqrt{12-r^2}} r \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^{\sqrt{3}} [rz]_{r^2}^{\sqrt{12-r^2}} dr \, d\theta \\
 &= \rho \int_0^{2\pi} \int_0^{\sqrt{3}} \left(r\sqrt{12-r^2} - r^3 \right) dr \, d\theta = \rho \int_0^{2\pi} \left[\left(-\frac{1}{2} \right) \left(\frac{2}{3} \right) (12-r^2)^{3/2} - \frac{1}{4} r^4 \right]_0^{\sqrt{3}} d\theta \\
 &= \rho \int_0^{2\pi} \left(-\frac{1}{3}(27) - \frac{9}{4} + \frac{1}{3}(12)^{3/2} \right) d\theta = \rho \int_0^{2\pi} \left(8\sqrt{3} - \frac{45}{4} \right) d\theta \\
 &= \rho \frac{32\sqrt{3} - 45}{4} (2\pi) = \frac{32\sqrt{3} - 45}{2} \rho\pi
 \end{aligned}$$

We now compute M_{xy} .

$$\begin{aligned}
 M_{xy} &= \int \int_E z \rho \, dV = \rho \int_0^{2\pi} \int_0^{\sqrt{3}} \int_{r^2}^{\sqrt{12-r^2}} rz \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^{\sqrt{3}} \left[\frac{1}{2} r z^2 \right]_{r^2}^{\sqrt{12-r^2}} dr \, d\theta \\
 &= \rho \int_0^{2\pi} \int_0^{\sqrt{3}} \left(6r - \frac{1}{2} r^3 - \frac{1}{2} r^5 \right) dr \, d\theta = \frac{\rho}{2} \int_0^{2\pi} \int_0^{\sqrt{3}} (12r - r^3 - r^5) dr \, d\theta \\
 &= \frac{\rho}{2} \int_0^{2\pi} \left[6r^2 - \frac{1}{4} r^4 - \frac{1}{6} r^6 \right]_0^{\sqrt{3}} d\theta = \frac{\rho}{2} \int_0^{2\pi} \left(6(3) - \frac{1}{4}(9) - \frac{1}{6}(27) \right) d\theta = \frac{\rho}{2} \int_0^{2\pi} \left(\frac{45}{4} \right) d\theta \\
 &= \frac{45\rho}{8} (2\pi) = \frac{45}{4} \rho\pi
 \end{aligned}$$

We may now compute

$$\bar{z} = \frac{M_{xy}}{M} = \frac{\frac{45}{4} \rho\pi}{\frac{32\sqrt{3}-45}{2} \rho\pi} = \frac{45}{2(32\sqrt{3} - 45)}$$

The center of mass is $\boxed{(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{45}{2(32\sqrt{3} - 45)}\right)}$.

45. Because the z -axis is a line of symmetry for the solid, we know that the center of mass must lie on the z -axis. That is $\bar{x} = 0$ and $\bar{y} = 0$. The projection of the solid E onto the xy -plane is bounded by $x^2 + y^2 = 4$. Using cylindrical coordinates we have $x^2 + y^2 = r^2$, so the solid is given by $r^2 \leq z \leq 4$, $0 \leq r \leq 2$, and $0 \leq \theta \leq 2\pi$. Using ρ to represent the density, the mass M of E is

$$\begin{aligned} M &= \int \int \int_E \rho \, dV = \rho \int_0^{2\pi} \int_0^2 \int_{r^2}^4 r \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^2 [rz]_{r^2}^4 \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^2 (4r - r^3) \, dr \, d\theta \\ &= \rho \int_0^{2\pi} \left[2r^2 - \frac{1}{4}r^4 \right]_0^2 d\theta = \rho \int_0^{2\pi} (4) \, d\theta = 4\rho(2\pi) = 8\rho\pi \end{aligned}$$

We now compute M_{xy} .

$$\begin{aligned} M_{xy} &= \int \int \int_E z\rho \, dV = \rho \int_0^{2\pi} \int_0^2 \int_{r^2}^4 rz \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^2 \left[\frac{1}{2}rz^2 \right]_{r^2}^4 \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^2 \left(8r - \frac{1}{2}r^5 \right) \, dr \, d\theta \\ &= \rho \int_0^{2\pi} \left[4r^2 - \frac{1}{12}r^6 \right]_0^2 d\theta = \rho \int_0^{2\pi} \left(16 - \frac{16}{3} \right) d\theta = \frac{32}{3}\rho(2\pi) = \frac{64}{3}\rho\pi \end{aligned}$$

We may now compute

$$\bar{z} = \frac{M_{xy}}{M} = \frac{\frac{64}{3}\rho\pi}{8\rho\pi} = \frac{8}{3}$$

The center of mass is $\boxed{(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{8}{3}\right)}$.

46. The projection of the solid E onto the xy -plane is bounded by $x^2 + y^2 = 1$. Using cylindrical coordinates $x^2 + y^2 + z^2 = 2$ becomes $r^2 + z^2 = 2$ so that $z = \sqrt{2 - r^2}$, $z \geq 0$. The solid is given by $0 \leq z \leq \sqrt{2 - r^2}$, $0 \leq r \leq 1$, and $0 \leq \theta \leq 2\pi$. Using ρ to represent the density, the mass M of E is

$$\begin{aligned} M &= \int \int \int_E \rho \, dV = \rho \int_0^{2\pi} \int_0^1 \int_0^{\sqrt{2-r^2}} r \, dz \, dr \, d\theta = \rho \int_0^{2\pi} \int_0^1 [rz]_0^{\sqrt{2-r^2}} \, dr \, d\theta \\ &= \rho \int_0^{2\pi} \int_0^1 \left(r\sqrt{2-r^2} \right) \, dr \, d\theta = \rho \int_0^{2\pi} \left[-\frac{1}{2}(2-r^2)^{3/2} \frac{2}{3} \right]_0^1 d\theta = \rho \int_0^{2\pi} \left(-\frac{1}{3} + \frac{2\sqrt{2}}{3} \right) d\theta \\ &= \frac{2\sqrt{2}-1}{3}\rho(2\pi) = \frac{2(2\sqrt{2}-1)}{3}\rho\pi \end{aligned}$$

The mass is $\boxed{\frac{2(2\sqrt{2}-1)}{3}\rho\pi}$.

47. The solid E that is formed by the intersection of the two cylinders can be described as $-\sqrt{1-x^2} \leq z \leq \sqrt{1-x^2}$ where $x^2 + y^2 \leq 1$ (see figure).

Though the solid involves the intersection of cylinders, its volume can be computed using rectangular coordinates. We compute the mass M of the solid as

$$\begin{aligned}
 M &= \iiint_E \rho \, dV = \rho \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} dz \, dy \, dx = \rho \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} [z]_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \, dy \, dx \\
 &= \rho \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} (2\sqrt{1-x^2}) \, dy \, dx = \rho \int_{-1}^1 \left[2\sqrt{1-x^2} y \right]_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \, dx \\
 &= \rho \int_{-1}^1 \left[2\sqrt{1-x^2} \cdot 2\sqrt{1-x^2} \right] \, dx = \rho \int_{-1}^1 4(1-x^2) \, dx = 4\rho \left[x - \frac{1}{3}x^3 \right]_{-1}^1 = \frac{16\rho}{3}
 \end{aligned}$$

The mass of the solid is $\boxed{\frac{16\rho}{3}}$.

48. For part (a), we use a CAS to plot the surface (see figure).

For part (b), we see that the mountain can be described in cylindrical coordinates as $0 \leq z \leq 5.3e^{-r^2}$, $0 \leq r \leq 2$, and $0 \leq \theta \leq 2\pi$. We may compute the volume V as

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^{2\pi} \int_0^2 \int_0^{5.3e^{-r^2}} r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^2 [rz]_0^{5.3e^{-r^2}} \, dr \, d\theta = \int_0^{2\pi} \int_0^2 \left(r(5.3e^{-r^2}) \right) \, dr \, d\theta \\
 &= \int_0^{2\pi} \left[-2.65e^{-r^2} \right]_0^2 \, d\theta = \int_0^{2\pi} (-2.65(e^{-4} - 1)) \, d\theta = \left(2.65 \left(1 - \frac{1}{e^4} \right) \right) (2\pi) \approx 16.345
 \end{aligned}$$

The volume is approximately $\boxed{16.345 \text{ km}^3}$.

49. From the limits of integration on z , we have $-r \leq z \leq \sqrt{16-r^2}$. In rectangular coordinates, we see that this corresponds to $-\sqrt{x^2+y^2} \leq z \leq \sqrt{16-x^2-y^2}$. The limits on r and θ indicate that the projection of the solid on the xy -plane is bounded by the circle centered at the origin with radius 4. That is, $x^2 + y^2 \leq 16$. We may describe this region as $-\sqrt{16-x^2} \leq y \leq \sqrt{16-x^2}$, $-4 \leq x \leq 4$. We may now express the given triple integral in rectangular coordinates.

$$\begin{aligned} \int_0^{2\pi} \int_0^4 \int_{-r}^{\sqrt{16-r^2}} z^2 r^5 \cos^4 \theta \, dz dr d\theta &= \int_0^{2\pi} \int_0^4 \int_{-r}^{\sqrt{16-r^2}} z^2 (r \cos \theta)^4 \cdot r \, dz dr d\theta \\ &= \int_{-4}^4 \int_{-\sqrt{16-x^2}}^{\sqrt{16-x^2}} \int_{-\sqrt{x^2+y^2}}^{\sqrt{16-x^2-y^2}} z^2 x^4 \, dz dy dx \end{aligned}$$

In rectangular coordinates, we have

$$\boxed{\int_{-4}^4 \int_{-\sqrt{16-x^2}}^{\sqrt{16-x^2}} \int_{-\sqrt{x^2+y^2}}^{\sqrt{16-x^2-y^2}} z^2 x^4 \, dz dy dx}.$$

50. From the limits of integration on z , we have $-r^2 \leq z \leq 9$. In rectangular coordinates, we see that this corresponds to $-(x^2+y^2) \leq z \leq 9$. The limits on r and θ indicate that the projection of the solid on the xy -plane is bounded by the portion of the circle centered at the origin with radius 2 in the first quadrant. That is, $x^2 + y^2 \leq 4$, $x \geq 0$, $y \geq 0$. We may describe this region as $0 \leq y \leq \sqrt{4-x^2}$, $0 \leq x \leq 2$. Note that $y = r \sin \theta$ implies that $\sin \theta = \frac{y}{r} = \frac{y}{\sqrt{x^2+y^2}}$. We may now express the given triple integral in rectangular coordinates.

$$\begin{aligned} \int_0^{\pi/2} \int_0^2 \int_{-r^2}^9 z^2 r^4 \sin^4 \theta \, dz dr d\theta &= \int_0^{\pi/2} \int_0^2 \int_{-r^2}^9 z^2 (r \sin \theta)^3 \sin \theta \cdot r \, dz dr d\theta \\ &= \int_0^2 \int_0^{\sqrt{4-x^2}} \int_{-(x^2+y^2)}^9 z^2 y^3 \frac{y}{\sqrt{x^2+y^2}} \, dz dy dx \\ &= \int_0^2 \int_0^{\sqrt{4-x^2}} \int_{-(x^2+y^2)}^9 \frac{z^2 y^4}{\sqrt{x^2+y^2}} \, dz dy dx \end{aligned}$$

In rectangular coordinates, we have

$$\boxed{\int_0^2 \int_0^{\sqrt{4-x^2}} \int_{-(x^2+y^2)}^9 \frac{z^2 y^4}{\sqrt{x^2+y^2}} \, dz dy dx}.$$

51. (a) For ease of notation below, we will refer to the radius R of the sphere as R_2 and the radius r of the hole as R_1 . By symmetry we may solve this problem by considering the hemisphere $z = \sqrt{R_2^2 - x^2 - y^2}$ and determining R_1 so that the hole removes half the volume of the hemisphere. We see that the projection onto the xy -plane is the region bounded by the circles $x^2 + y^2 = R_1^2$ and $x^2 + y^2 = R_2^2$. Converting to cylindrical coordinates, the hemisphere with a hole drilled through it is given by $0 \leq z \leq \sqrt{R_2^2 - r^2}$, $R_1 \leq r \leq R_2$, and $0 \leq \theta \leq 2\pi$. The volume V of this solid E is given by

$$\begin{aligned} V &= \iiint_E dV = \int_0^{2\pi} \int_{R_1}^{R_2} \int_0^{\sqrt{R_2^2-r^2}} r \, dz dr d\theta = \int_0^{2\pi} \int_{R_1}^{R_2} [rz]_0^{\sqrt{R_2^2-r^2}} dr d\theta \\ &= \int_0^{2\pi} \int_{R_1}^{R_2} \left(r \sqrt{R_2^2 - r^2} \right) dr d\theta = \int_0^{2\pi} \left[-\frac{1}{2} (R_2^2 - r^2)^{3/2} \frac{2}{3} \right]_{R_1}^{R_2} d\theta = \int_0^{2\pi} \left(\frac{1}{3} (R_2^2 - R_1^2)^{3/2} \right) d\theta \\ &= \frac{2\pi}{3} (R_2^2 - R_1^2)^{3/2} \end{aligned}$$

From this calculation, we see that the total volume of the sphere described in the problem statement is $\frac{4\pi}{3}(R_2^2 - R_1^2)^{3/2}$. Now we wish to find R_1 such that this volume equals half the volume of a sphere with radius R_2 with no hole. That is, we will solve for R_1 in the equation

$$\begin{aligned}\frac{4\pi}{3}(R_2^2 - R_1^2)^{3/2} &= \frac{1}{2} \left(\frac{4\pi}{3} R_2^3 \right) \\ (R_2^2 - R_1^2)^{3/2} &= \frac{1}{2} R_2^3 \\ R_2^2 - R_1^2 &= \frac{1}{2^{2/3}} R_2^2 \\ R_1^2 &= R_2^2 \left(1 - \frac{1}{2^{2/3}} \right) \\ R_1 &= \sqrt{R_2^2 \frac{2^{2/3} - 1}{2^{2/3}}} \\ R_1 &= R_2 \sqrt{\frac{2^{2/3} - 1}{2^{2/3}}}\end{aligned}$$

To remove half the volume of a sphere of radius R , drill a hole of radius $R\sqrt{\frac{2^{2/3} - 1}{2^{2/3}}}$ cm through the center of the sphere.

For part (b), we substitute $R = 10$ into the formula found in part (a) to find $r \approx 6.083$ cm.

52. The projection of the solid E onto the xy -plane is found by finding the intersection of the surfaces $4z = x^2 + y^2$ and $x^2 + y^2 + z^2 = 5$. Substituting $4z = x^2 + y^2$ into $x^2 + y^2 + z^2 = 5$, we obtain $4z + z^2 = 5$ which means $z^2 + 4z - 5 = 0$ or $(z + 5)(z - 1) = 0$. We see that this implies $z = -5$ or $z = 1$, but we must have $z \geq 0$ since $z = \frac{1}{4}(x^2 + y^2)$, so $z = 1$. Substituting $z = 1$ into $4z = x^2 + y^2$ we get the curve of intersection to be $x^2 + y^2 = 4$, which is the bounding curve for the projection of E onto the xy plane. Using cylindrical coordinates $x^2 + y^2 = r^2$ and $\sqrt{5 - x^2 - y^2} = \sqrt{5 - r^2}$, so the solid is given by $\frac{1}{4}r^2 \leq z \leq \sqrt{5 - r^2}$, $0 \leq r \leq 2$, and $0 \leq \theta \leq 2\pi$. We compute the volume V as

$$\begin{aligned}V &= \int \int \int_E dV = \int_0^{2\pi} \int_0^2 \int_{\frac{1}{4}r^2}^{\sqrt{5-r^2}} r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^2 [rz]_{\frac{1}{4}r^2}^{\sqrt{5-r^2}} \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^2 \left(r\sqrt{5-r^2} - \frac{1}{4}r^3 \right) \, dr \, d\theta = \int_0^{2\pi} \left[\left(-\frac{1}{2} \right) \left(\frac{2}{3} \right) (5-r^2)^{3/2} - \frac{1}{16}r^4 \right]_0^2 \, d\theta \\ &= \int_0^{2\pi} \left(-\frac{1}{3} - 1 + \frac{1}{3}(5)^{3/2} \right) \, d\theta = \int_0^{2\pi} \left(\frac{5\sqrt{5}}{3} - \frac{4}{3} \right) \, d\theta = \frac{5\sqrt{5}-4}{3}(2\pi) = \frac{2\pi(5\sqrt{5}-4)}{3}\end{aligned}$$

The volume of the solid is $\frac{2\pi(5\sqrt{5}-4)}{3}$ cubic units.

53. We will define the two pipes using the equations $x^2 + y^2 = r^2$ and $x^2 + z^2 = r^2$. The solid E that is formed by the intersection of the two cylinders can be described as $-\sqrt{r^2 - x^2} \leq z \leq \sqrt{r^2 - x^2}$ where $x^2 + y^2 \leq r^2$. Though the solid involves the intersection of cylinders, its volume is can be computed

using rectangular coordinates. We compute the volume V of the solid as

$$\begin{aligned}
 V &= \int \int \int_E dV = \int_{-r}^r \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} dz dy dx = \int_{-r}^r \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} [z]_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} dy dx \\
 &= \int_{-r}^r \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} (2\sqrt{r^2-x^2}) dy dx = \int_{-r}^r [2\sqrt{r^2-x^2} y]_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} dx \\
 &= \int_{-r}^r [2\sqrt{r^2-x^2} \cdot 2\sqrt{r^2-x^2}] dx = \int_{-r}^r 4(r^2-x^2) dx = 4 \left[r^2 x - \frac{1}{3} x^3 \right]_{-r}^r = \frac{16r^3}{3}
 \end{aligned}$$

To determine r such that the volume is 10 m^3 , we substitute $V = 10$ into the equation $V = \frac{16r^3}{3}$ and

solve for r . That is, we solve $10 = \frac{16r^3}{3}$ to get $r = \frac{\sqrt[3]{15}}{2} \text{ m}$.

14.8 Triple Integrals Using Spherical Coordinates

Concepts and Vocabulary

1. In spherical coordinates, the number ρ equals the distance from the *origin* to the point P .
2. In spherical coordinates, ϕ is the angle between the positive z -axis and the line segment OP .
3. False. The correct equations are $x = \rho \sin \phi \cos \theta$, $y = \rho \sin \phi \sin \theta$, and $z = \rho \cos \phi$.
4. True. See Equation (2) in Objective 1.
5. $dV = \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi$. See Objective 2.
6. In spherical coordinates, the surface described by the equation $\rho = a$, where $a > 0$ is a constant, is a *sphere of radius a* .

Skill Building

7. Since the z -coordinate in cylindrical coordinates is $-\frac{2\sqrt{3}}{3}$, that is the z -coordinate in rectangular coordinates as well. Next, we know that $\tan \theta = \frac{y}{x}$, so that $\tan \frac{\pi}{6} = \frac{y}{1} = y$, or $y = \frac{\sqrt{3}}{3}$. So the rectangular coordinates of the point are $\left(1, \frac{\sqrt{3}}{3}, -\frac{2\sqrt{3}}{3}\right)$. Then

$$r = \sqrt{x^2 + y^2} = \sqrt{1^2 + \left(\frac{\sqrt{3}}{3}\right)^2} = \sqrt{\frac{4}{3}} = \frac{2\sqrt{3}}{3}$$

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + \left(\frac{\sqrt{3}}{3}\right)^2 + \left(-\frac{2\sqrt{3}}{3}\right)^2} = \sqrt{\frac{8}{3}} = \frac{2\sqrt{6}}{3}.$$

Next, $\cos \phi = \frac{z}{\rho}$, so that

$$\cos \phi = \frac{-(2\sqrt{3}/3)}{(2\sqrt{6}/3)} = -\frac{\sqrt{2}}{2},$$

so that $\phi = \frac{3\pi}{4}$. Finally, θ is the same in cylindrical and spherical coordinates. So the three sets of coordinates are:

rectangular : $(x, y, z) = \left(1, \frac{\sqrt{3}}{3}, -\frac{2\sqrt{3}}{3}\right)$ cylindrical : $(r, \theta, z) = \left(\frac{2\sqrt{3}}{3}, \frac{\pi}{6}, -\frac{2\sqrt{3}}{3}\right)$ spherical : $(\rho, \theta, \phi) = \left(\frac{2\sqrt{6}}{3}, \frac{\pi}{6}, \frac{3\pi}{4}\right)$
--

8. Since the z -coordinate in rectangular coordinates is $2\sqrt{2}$, that is the z -coordinate in cylindrical coordinates as well. Since θ is the same in cylindrical and spherical coordinates, we get for the cylindrical coordinates of the point $(\sqrt{8}, \frac{\pi}{6}, 2\sqrt{2})$. Next, $\tan \theta = \frac{y}{x}$, so that $\tan \frac{\pi}{6} = \frac{y}{x}$, or $\frac{y}{x} = \frac{\sqrt{3}}{3}$, which can be rewritten as $y^2 = \frac{1}{3}x^2$. Also $r^2 = x^2 + y^2 = 8$; substituting in the value for y^2 gives $x^2 + \frac{1}{3}x^2 = \frac{4}{3}x^2 = 8$, so that $x = \pm\sqrt{6}$ and $y = \pm\sqrt{2}$. Since $\theta = \frac{\pi}{6}$, the point $(x, y, 0)$ lies in the first quadrant, so we take both plus signs. Therefore the rectangular coordinates of the point are $(\sqrt{6}, \sqrt{2}, 2\sqrt{2})$. It follows that

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{(\sqrt{6})^2 + (\sqrt{2})^2 + (2\sqrt{2})^2} = 4.$$

Finally, $\cos \phi = \frac{z}{\rho}$, so that

$$\cos \phi = \frac{2\sqrt{2}}{4} = \frac{\sqrt{2}}{2},$$

and therefore $\phi = \frac{\pi}{4}$. So we get

rectangular : $(x, y, z) = (\sqrt{6}, \sqrt{2}, 2\sqrt{2})$ cylindrical : $(r, \theta, z) = (\sqrt{8}, \frac{\pi}{6}, 2\sqrt{2})$ spherical : $(\rho, \theta, \phi) = (4, \frac{\pi}{6}, \frac{\pi}{4})$.
--

9. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{(-\sqrt{2})^2 + (-\sqrt{2})^2 + (2\sqrt{3})^2} = 4$, and $\tan \theta = \frac{y}{x} = \frac{-\sqrt{2}}{-\sqrt{2}} = 1$. Since both x and y are negative, θ is in the third quadrant, so we get $\theta = \frac{5\pi}{4}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{2\sqrt{3}}{4} = \frac{\sqrt{3}}{2}$, so that

$\phi = \frac{\pi}{6}$. The spherical coordinates are $\left(4, \frac{5\pi}{4}, \frac{\pi}{6}\right)$.

10. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{(-1)^2 + (\sqrt{3})^2 + 2^2} = 2\sqrt{2}$, and $\tan \theta = \frac{y}{x} = -\sqrt{3}$. Since x is negative and y positive, this is a second quadrant angle, so that $\theta = \frac{2\pi}{3}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{2}{2\sqrt{2}} = \frac{\sqrt{2}}{2}$, so that

$\phi = \frac{\pi}{4}$. The spherical coordinates are $\left(2\sqrt{2}, \frac{2\pi}{3}, \frac{\pi}{4}\right)$.

11. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + 1^2 + (\sqrt{2})^2} = 2$, and $\tan \theta = \frac{y}{x} = 1$. Since x and y are both positive, this is a first quadrant angle, so that $\theta = \frac{\pi}{4}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{\sqrt{2}}{2}$, so that $\phi = \frac{\pi}{4}$. The spherical

coordinates are $\left(2, \frac{\pi}{4}, \frac{\pi}{4}\right)$.

12. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + (-\sqrt{3})^2 + (-2)^2} = 2\sqrt{2}$, and $\tan \theta = \frac{y}{x} = -\sqrt{3}$. Since x is positive and y negative, this is a fourth quadrant angle, so that $\theta = \frac{5\pi}{3}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{-2}{2\sqrt{2}} = -\frac{\sqrt{2}}{2}$, so that

$\phi = \frac{3\pi}{4}$. The spherical coordinates are $\left(2\sqrt{2}, \frac{5\pi}{3}, \frac{3\pi}{4}\right)$.

13. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + 2^2 + 3^2} = \sqrt{14}$, and $\tan \theta = \frac{y}{x} = 2$. Since x and y are both positive, this is a first quadrant angle, so that $\theta = \tan^{-1}(2)$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{3}{\sqrt{14}}$, so that $\phi = \cos^{-1}\left(\frac{3}{\sqrt{14}}\right)$.

The spherical coordinates are $\left(\sqrt{14}, \tan^{-1}(2), \cos^{-1}\left(\frac{3}{\sqrt{14}}\right)\right)$.

14. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + (-1)^2 + (\sqrt{2})^2} = 2$, and $\tan \theta = \frac{y}{x} = -1$. Since x is positive and y negative, this is a fourth quadrant angle, so that $\theta = \frac{7\pi}{4}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{\sqrt{2}}{2}$, so that $\phi = \frac{\pi}{4}$. The

spherical coordinates are $\left(2, \frac{7\pi}{4}, \frac{\pi}{4}\right)$.

15. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{0^2 + (3\sqrt{3})^2 + 3^2} = 6$. Since $x = 0$, $\tan \theta$ is undefined, so that $\theta = \frac{\pi}{2}$ or $\frac{3\pi}{2}$. Since y is positive, we see that $\theta = \frac{\pi}{2}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{3}{6} = \frac{1}{2}$, so that $\phi = \frac{\pi}{3}$. The spherical

coordinates are $\left(6, \frac{\pi}{2}, \frac{\pi}{3}\right)$.

16. $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{(-5\sqrt{3})^2 + 5^2 + 0^2} = 10$, and $\tan \theta = \frac{y}{x} = -\frac{\sqrt{3}}{3}$. Since x is negative and y positive, this is a second quadrant angle, so that $\theta = \frac{5\pi}{6}$. Finally, $\cos \phi = \frac{z}{\rho} = 0$, so that $\phi = \frac{\pi}{2}$. The spherical coordinates are $\boxed{\left(10, \frac{5\pi}{6}, \frac{\pi}{2}\right)}$.

17. Computing gives

$$\begin{aligned}
 \int_0^{\pi/2} \int_0^{\sin \phi} \int_0^{\pi/4} \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi &= \int_0^{\pi/2} \int_0^{\sin \phi} [\rho^2 \theta \sin \phi]_0^{\pi/4} \, d\rho \, d\phi \\
 &= \frac{\pi}{4} \int_0^{\pi/2} \int_0^{\sin \phi} \rho^2 \sin \phi \, d\rho \, d\phi \\
 &= \frac{\pi}{4} \int_0^{\pi/2} \left[\frac{1}{3} \rho^3 \sin \phi \right]_0^{\sin \phi} \, d\phi \\
 &= \frac{\pi}{12} \int_0^{\pi/2} \sin^4 \phi \, d\phi.
 \end{aligned}$$

Using Formulas 84 and 90 in the Table of Integrals, we get

$$\begin{aligned}
 \frac{\pi}{12} \int_0^{\pi/2} \sin^4 \phi \, d\phi &= \frac{\pi}{12} \left(\left[-\frac{1}{4} \sin^3 \phi \cos \phi \right]_0^{\pi/2} + \frac{3}{4} \int_0^{\pi/2} \sin^2 \phi \, d\phi \right) \\
 &= \frac{\pi}{16} \int_0^{\pi/2} \sin^2 \phi \, d\phi \\
 &= \frac{\pi}{16} \left[\frac{\phi}{2} - \frac{\sin 2\phi}{4} \right]_0^{\pi/2} = \boxed{\frac{\pi^2}{64}}.
 \end{aligned}$$

18. Computing gives

$$\begin{aligned}
 \int_0^{\pi/2} \int_0^{\pi/2} \int_0^{\sin \phi} \rho^2 \sin \phi \cos \phi \, d\rho \, d\theta \, d\phi &= \int_0^{\pi/2} \int_0^{\pi/2} \left[\frac{1}{3} \rho^3 \sin \phi \cos \phi \right]_0^{\sin \phi} \, d\theta \, d\phi \\
 &= \frac{1}{3} \int_0^{\pi/2} \int_0^{\pi/2} \sin^4 \phi \cos \phi \, d\theta \, d\phi \\
 &= \frac{1}{3} \int_0^{\pi/2} [\theta \sin^4 \phi \cos \phi]_0^{\pi/2} \, d\phi \\
 &= \frac{\pi}{6} \int_0^{\pi/2} \sin^4 \phi \cos \phi \, d\phi \\
 &= \frac{\pi}{6} \left[\frac{1}{5} \sin^5 \phi \right]_0^{\pi/2} = \boxed{\frac{\pi}{30}}.
 \end{aligned}$$

19. Computing gives

$$\begin{aligned}
 \int_0^{2\pi} \int_0^{\pi/4} \int_0^{\sec \phi} \rho^2 \sin^2 \phi \, d\rho \, d\phi \, d\theta &= \int_0^{2\pi} \int_0^{\pi/4} \left[\frac{1}{3} \rho^3 \sin^2 \phi \right]_0^{\sec \phi} d\phi \, d\theta \\
 &= \frac{1}{3} \int_0^{2\pi} \int_0^{\pi/4} \frac{\sin^2 \phi}{\cos^3 \phi} d\phi \, d\theta \\
 &= \frac{1}{3} \int_0^{2\pi} \int_0^{\pi/4} \tan^2 \phi \sec \phi \, d\phi \, d\theta \\
 &= \frac{1}{3} \int_0^{2\pi} \int_0^{\pi/4} (\sec^2 \phi - 1) \sec \phi \, d\phi \, d\theta \\
 &= \frac{1}{3} \int_0^{2\pi} \int_0^{\pi/4} (\sec^3 \phi - \sec \phi) \, d\phi \, d\theta.
 \end{aligned}$$

Using Formula 88 from the Table of Integrals (or see Example 7 in Section 7.2), we get

$$\begin{aligned}
 \frac{1}{3} \int_0^{2\pi} \int_0^{\pi/4} (\sec^3 \phi - \sec \phi) \, d\phi \, d\theta &= \frac{1}{3} \int_0^{2\pi} \left[\frac{1}{2} (\sec \phi \tan \phi + \ln(\sec \phi + \tan \phi)) - \ln(\sec \phi + \tan \phi) \right]_0^{\pi/4} d\theta \\
 &= \frac{1}{6} \int_0^{2\pi} [\sec \phi \tan \phi - \ln(\sec \phi + \tan \phi)]_0^{\pi/4} d\theta \\
 &= \frac{1}{6} \int_0^{2\pi} \left((\sqrt{2} \cdot 1 - \ln(\sqrt{2} + 1)) - (1 \cdot 0 - \ln(1 + 0)) \right) d\theta \\
 &= \frac{1}{6} \int_0^{2\pi} (\sqrt{2} - \ln(1 + \sqrt{2})) \, d\theta \\
 &= \frac{\pi}{3} (\sqrt{2} - \ln(1 + \sqrt{2})).
 \end{aligned}$$

This can be simplified to $\boxed{\frac{\pi}{3}(\sqrt{2} + \ln(\sqrt{2} - 1))}$.

20. Computing gives

$$\begin{aligned}
 \int_0^{\pi/4} \int_0^{\cos \phi} \int_0^{2\pi} \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi &= 2\pi \int_0^{\pi/4} \int_0^{\cos \phi} \rho^2 \sin \phi \, d\rho \, d\phi \\
 &= 2\pi \int_0^{\pi/4} \left[\frac{1}{3} \rho^3 \sin \phi \right]_0^{\cos \phi} d\phi \\
 &= \frac{2\pi}{3} \int_0^{\pi/4} \cos^3 \phi \sin \phi \, d\phi \\
 &= \frac{2\pi}{3} \left[-\frac{1}{4} \cos^4 \phi \right]_0^{\pi/4} = \frac{2\pi}{3} \left(-\frac{1}{16} + \frac{1}{4} \right) = \boxed{\frac{\pi}{8}}.
 \end{aligned}$$

21. The region is:

This region is the upper half of a sphere of radius 2 centered at $(0, 0, 2)$. In spherical coordinates, θ is unrestricted, so the range is $0 \leq \theta \leq 2\pi$. The lower edge of the hemisphere has a boundary along a circle of radius 2 in the plane $z = 2$, so that a point on that circle is for example $(2, 0, 2)$. Then $\cos \phi = \frac{z}{\rho} = \frac{2}{\sqrt{2^2 + 2^2}} = \frac{\sqrt{2}}{2}$, so that $\phi = \frac{\pi}{4}$ at the lower edge of the hemisphere. Therefore the range of ϕ is $0 \leq \phi \leq \frac{\pi}{4}$. For a given value of ϕ , the corresponding maximum value of ρ can be seen from the following projection of the figure above in the xz -plane:

Since the triangle shown is inscribed in a semicircle, it is a right triangle, so that $\cos \phi = \frac{\rho}{4}$ and therefore

$\rho = 4 \cos \phi$. Putting this all together, we get

$$\begin{aligned}
 \int_{-2}^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} \int_2^{2+\sqrt{4-x^2-y^2}} y \, dz \, dx \, dy &= \int_0^{\pi/4} \int_0^{4 \cos \phi} \int_0^{2\pi} \rho \sin \phi \sin \theta \cdot \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi \\
 &= \int_0^{\pi/4} \int_0^{4 \cos \phi} \int_0^{2\pi} \rho^3 \sin^2 \phi \sin \theta \, d\theta \, d\rho \, d\phi \\
 &= \int_0^{\pi/4} \int_0^{4 \cos \phi} \left[-\rho^3 \sin^2 \phi \cos \theta \right]_0^{2\pi} d\rho \, d\phi \\
 &= \boxed{0}.
 \end{aligned}$$

22. The region is:

This is a sphere of radius 3 centered at the origin, so converting to spherical coordinates and using the appropriate equations for x , y , and z in the integrand gives

$$\begin{aligned}
 \int_{-3}^3 \int_{-\sqrt{9-x^2}}^{\sqrt{9-x^2}} \int_{-\sqrt{9-x^2-y^2}}^{\sqrt{9-x^2-y^2}} (x^2 z + y^2 z + z^3) \, dz \, dy \, dx \\
 &= \int_{-3}^3 \int_{-\sqrt{9-x^2}}^{\sqrt{9-x^2}} \int_{-\sqrt{9-x^2-y^2}}^{\sqrt{9-x^2-y^2}} z (x^2 + y^2 + z^2) \, dz \, dy \, dx \\
 &= \int_0^3 \int_0^{\pi} \int_0^{2\pi} \rho \cos \phi \cdot \rho^2 \cdot \rho^2 \sin \phi \, d\theta \, d\phi \, d\rho \\
 &= 2\pi \int_0^3 \int_0^{\pi} \rho^5 \cos \phi \sin \phi \, d\phi \, d\rho \\
 &= 2\pi \int_0^3 \left[\frac{1}{2} \rho^5 \sin^2 \phi \right]_0^{\pi} d\rho \\
 &= \boxed{0}.
 \end{aligned}$$

23. The region is:

The bounds of the region in the z direction are from $z = \sqrt{x^2 + y^2}$, which is the cone $\phi = \frac{\pi}{4}$ to $z = \sqrt{1 - x^2 - y^2}$, which is a sphere of radius 1. Since the region lies over the first quadrant in the xy -plane, $0 \leq \theta \leq \frac{\pi}{2}$. So the integral becomes

$$\begin{aligned}
 \int_0^1 \int_0^{\sqrt{1-y^2}} \int_{\sqrt{x^2+y^2}}^{\sqrt{1-x^2-y^2}} (x^2 + y^2 + z^2)^{3/2} dz dx dy &= \int_0^1 \int_0^{\pi/2} \int_0^{\pi/4} (\rho^2)^{3/2} \cdot \rho^2 \sin \phi d\phi d\theta d\rho \\
 &= \int_0^1 \int_0^{\pi/2} \int_0^{\pi/4} \rho^5 \sin \phi d\phi d\theta d\rho \\
 &= \int_0^1 \int_0^{\pi/2} [-\rho^5 \cos \phi]_0^{\pi/4} d\theta d\rho \\
 &= \left(\frac{2 - \sqrt{2}}{2} \right) \int_0^1 \int_0^{\pi/2} \rho^5 d\theta d\rho \\
 &= \frac{\pi}{2} \left(1 - \frac{\sqrt{2}}{2} \right) \int_0^1 \rho^5 d\rho \\
 &= \frac{\pi}{2} \left(1 - \frac{\sqrt{2}}{2} \right) \left[\frac{1}{6} \rho^6 \right]_0^1 \\
 &= \frac{\pi}{12} \left(1 - \frac{\sqrt{2}}{2} \right) \\
 &= \boxed{\frac{\pi}{24} (2 - \sqrt{2})}.
 \end{aligned}$$

24. The region is:

This is the portion of the sphere of radius 1 where $x, y, z \geq 0$; this can also be seen from the bounds of the integration; since $0 \leq z \leq \sqrt{1 - x^2 - y^2}$, we get $0 \leq z^2 \leq 1 - x^2 - y^2$, so that $x^2 + y^2 + z^2$ ranges from 0 to 1. Similarly, $x^2 + y^2$ ranges from 0 to 1 when $z = 0$. Therefore $0 \leq \rho \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$, and $0 \leq \phi \leq \frac{\pi}{2}$, so the integral is

$$\begin{aligned}
 \int_0^1 \int_0^{\sqrt{1-y^2}} \int_0^{\sqrt{1-x^2-y^2}} e^{(x^2+y^2+z^2)^{3/2}} dz dx dy &= \int_0^1 \int_0^{\pi/2} \int_0^{\pi/2} e^{(\rho^2)^{3/2}} \rho^2 \sin \phi d\phi d\theta d\rho \\
 &= \int_0^1 \int_0^{\pi/2} \int_0^{\pi/2} \rho^2 e^{\rho^3} \sin \phi d\phi d\theta d\rho \\
 &= \int_0^1 \int_0^{\pi/2} \left[-\rho^2 e^{\rho^3} \cos \phi \right]_0^{\pi/2} d\theta d\rho \\
 &= \int_0^1 \int_0^{\pi/2} \rho^2 e^{\rho^3} d\theta d\rho \\
 &= \frac{\pi}{2} \int_0^1 \rho^2 e^{\rho^3} d\rho.
 \end{aligned}$$

Now use the substitution $u = \rho^3$, so that $du = 3\rho^2 d\rho$. Then $\rho = 0$ corresponds to $u = 0$, and $\rho = 1$ to $u = 1$, and we get

$$\frac{\pi}{2} \int_0^1 \rho^2 e^{\rho^3} d\rho = \frac{\pi}{2} \cdot \frac{1}{3} \int_0^1 e^u du = \frac{\pi}{6} [e^u]_0^1 = \boxed{\frac{\pi}{6}(e - 1)}.$$

Applications and Extensions

25. The region is:

Setting $x = 1$ and $y = 0$ in the equation of the cone gives $z = -\sqrt{3}$, so that the angle ϕ corresponding to this point satisfies $\cos \phi = \frac{z}{\rho} = \frac{-\sqrt{3}}{\sqrt{1^2+0^2+(-\sqrt{3})^2}} = -\frac{\sqrt{3}}{2}$. Therefore $\phi = \frac{5\pi}{6}$. The integrand is $\sqrt{x^2 + y^2 + z^2} = \rho$, so the integral is

$$\begin{aligned}
 \int_0^2 \int_0^{2\pi} \int_0^{5\pi/6} \rho \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho &= \int_0^2 \int_0^{2\pi} \int_0^{5\pi/6} \rho^3 \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= \int_0^2 \int_0^{2\pi} [-\rho^3 \cos \phi]_0^{5\pi/6} \, d\theta \, d\rho \\
 &= \int_0^2 \int_0^{2\pi} \rho^3 \left(1 + \frac{\sqrt{3}}{2}\right) \, d\theta \, d\rho \\
 &= \left(1 + \frac{\sqrt{3}}{2}\right) \int_0^2 \int_0^{2\pi} \rho^3 \, d\theta \, d\rho \\
 &= 2\pi \left(1 + \frac{\sqrt{3}}{2}\right) \int_0^2 \rho^3 \, d\rho \\
 &= \pi (2 + \sqrt{3}) \left[\frac{1}{4}\rho^4\right]_0^2 \\
 &= \boxed{4\pi(2 + \sqrt{3})}.
 \end{aligned}$$

26. The two concentric spheres have radii 1 and 2, and the integrand is $\sqrt{x^2 + y^2 + z^2} = \sqrt{\rho^2} = \rho$, so the

integral is

$$\begin{aligned}
 \int_0^{2\pi} \int_0^\pi \int_1^2 \rho \cdot \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta &= \int_0^{2\pi} \int_0^\pi \int_1^2 \rho^3 \sin \phi \, d\rho \, d\phi \, d\theta \\
 &= \int_0^{2\pi} \int_0^\pi \left[\frac{1}{4} \rho^4 \sin \phi \right]_1^2 \, d\phi \, d\theta \\
 &= \frac{15}{4} \int_0^{2\pi} \int_0^\pi \sin \phi \, d\phi \, d\theta \\
 &= \frac{15}{4} \int_0^{2\pi} [-\cos \phi]_0^\pi \, d\theta \\
 &= \frac{15}{2} \int_0^{2\pi} 1 \, d\theta \\
 &= \boxed{15\pi}.
 \end{aligned}$$

27. The region is:

This region has rotational symmetry about the z -axis, so cylindrical coordinates are appropriate. The integrand is $\sqrt{x^2 + y^2} = \sqrt{r^2} = r$, so that $0 \leq r \leq 2$ and $0 \leq z \leq 2$. From the diagram, $0 \leq \theta \leq \frac{\pi}{2}$. The integral is

$$\begin{aligned}
 \int_0^2 \int_0^2 \int_0^{\sqrt{4-x^2}} \sqrt{x^2 + y^2} \, dy \, dx \, dz &= \int_0^2 \int_0^2 \int_0^{\pi/2} r \cdot r \, d\theta \, dz \, dr \\
 &= \int_0^2 \int_0^2 [r^2 \theta]_0^{\pi/2} \, dz \, dr \\
 &= \frac{\pi}{2} \int_0^2 \int_0^2 r^2 \, dz \, dr \\
 &= \pi \int_0^2 r^2 \, dr \\
 &= \pi \left[\frac{1}{3} r^3 \right]_0^2 = \boxed{\frac{8}{3}\pi}.
 \end{aligned}$$

28. The region is:

This is the portion of a sphere of radius 2 lying in the first octant, so the spherical coordinate integration limits are $0 \leq \rho \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$, $0 \leq \phi \leq \frac{\pi}{2}$. The integrand is

$$\begin{aligned} \frac{2z}{\sqrt{x^2 + y^2}} &= \frac{2\rho \cos \phi}{\sqrt{\rho^2 \cos^2 \theta \sin^2 \phi + \rho^2 \sin^2 \theta \sin^2 \phi}} \\ &= \frac{2\rho \cos \phi}{\rho \sin \phi \sqrt{\cos^2 \theta + \sin^2 \theta}} \\ &= 2 \cot \phi. \end{aligned}$$

Therefore the integral is

$$\begin{aligned} \int_0^2 \int_0^{\sqrt{4-y^2}} \int_0^{\sqrt{4-x^2-y^2}} \frac{2z}{\sqrt{x^2 + y^2}} dz dx dy &= \int_0^2 \int_0^{\pi/2} \int_0^{\pi/2} 2 \cot \phi \cdot \rho^2 \sin \phi d\phi d\theta d\rho \\ &= \int_0^2 \int_0^{\pi/2} \int_0^{\pi/2} 2\rho^2 \cos \phi d\phi d\theta d\rho \\ &= 2 \int_0^2 \int_0^{\pi/2} [\rho^2 \sin \phi]_0^{\pi/2} d\theta d\rho \\ &= 2 \int_0^2 \int_0^{\pi/2} \rho^2 d\theta d\rho \\ &= \pi \int_0^2 \rho^2 d\rho \\ &= \pi \left[\frac{1}{3} \rho^3 \right]_0^2 = \boxed{\frac{8}{3} \pi}. \end{aligned}$$

29. In rectangular coordinates, x ranges from $-a$ to a . For each value of x , values of y that stay within the sphere range from $-\sqrt{a^2 - x^2}$ to $\sqrt{a^2 - x^2}$. Finally, for given values of y and x , values of z range from $-\sqrt{a^2 - x^2 - y^2}$ to $\sqrt{a^2 - x^2 - y^2}$. Therefore the integral in rectangular coordinates is

$$\int_{-a}^a \int_{-\sqrt{a^2 - x^2}}^{\sqrt{a^2 - x^2}} \int_{-\sqrt{a^2 - x^2 - y^2}}^{\sqrt{a^2 - x^2 - y^2}} f(x, y, z) dz dy dx.$$

In cylindrical coordinates, r ranges from 0 to a , and θ ranges from 0 to 2π . To determine the range of z , consider the projection of the sphere onto the xz -plane:

For a given value of r , z ranges from $-\sqrt{a^2 - r^2}$ to $\sqrt{a^2 - r^2}$, and the integral is

$$\int_0^{2\pi} \int_0^a \int_{-\sqrt{a^2-r^2}}^{\sqrt{a^2-r^2}} f(x(r, \theta), y(r, \theta), z) r \, dr \, d\theta \, dz.$$

In spherical coordinates, the sphere has ranges $0 \leq \rho \leq a$, $0 \leq \theta \leq 2\pi$, and $0 \leq \phi \leq \pi$, so the integral is

$$\int_0^{2\pi} \int_0^\pi \int_0^a f(x(\rho, \theta, \phi), y(\rho, \theta, \phi), z(\rho, \theta, \phi)) \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta.$$

30. The region is:

In rectangular coordinates, we let x go from -2 for 2 ; for each value of x , values of y range from $-\sqrt{4 - x^2}$ to $\sqrt{4 - x^2}$ to remain within the cylinder. For each pair of values of x and y , z ranges from

$-\sqrt{9-x^2-y^2}$ to $\sqrt{9-x^2-y^2}$, remaining within the sphere. So the integral is

$$\int_{-2}^2 \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} \int_{-\sqrt{9-x^2-y^2}}^{\sqrt{9-x^2-y^2}} f(x, y, z) dz dy dx.$$

In cylindrical coordinates, r ranges from 0 to 2, and θ from 0 to 2π . Since $r = \sqrt{x^2 + y^2}$, we must have $r^2 + z^2 \leq 9$, so that z ranges from $-\sqrt{9-r^2}$ to $\sqrt{9-r^2}$, and the integral is

$$\int_0^2 \int_0^{2\pi} \int_{-\sqrt{9-r^2}}^{\sqrt{9-r^2}} f(x(r, \theta), y(r, \theta), z) r dz d\theta dr.$$

In spherical coordinates, θ ranges from 0 to 2π . To determine the other two ranges, look at a projection of the region onto the xz -plane:

The point of intersection of the projections of the cylinder and the sphere in the first quadrant is the intersection of the line $x = 2$ with the circle $x^2 + z^2 = 9$, so it is the point $(2, \sqrt{5})$. This point corresponds to an angle $\phi = \tan^{-1}\left(\frac{2}{\sqrt{5}}\right)$. The equivalent point in the fourth quadrant corresponds to $\phi = \pi + \tan^{-1}\left(-\frac{2}{\sqrt{5}}\right)$. For $0 \leq \phi \leq \tan^{-1}\left(\frac{2}{\sqrt{5}}\right)$ and $\pi + \tan^{-1}\left(-\frac{2}{\sqrt{5}}\right) \leq \phi \leq \pi$, we can integrate from $\rho = 0$ to $\rho = 3$. In between those two values, however, the radius of integration changes as ϕ changes. From the diagram, for a given value of ϕ , ρ ranges from 0 to $2 \csc \phi$. Therefore the integral is a sum of three integrals:

$$\begin{aligned} & \int_0^{2\pi} \int_0^{\tan^{-1}(2/\sqrt{5})} \int_0^3 f(x(\rho, \theta, \phi), y(\rho, \theta, \phi), z(\rho, \theta, \phi)) d\rho d\phi d\theta + \\ & \int_0^{2\pi} \int_{\pi + \tan^{-1}(-2/\sqrt{5})}^{\pi} \int_0^3 f(x(\rho, \theta, \phi), y(\rho, \theta, \phi), z(\rho, \theta, \phi)) d\rho d\phi d\theta + \\ & \int_0^{2\pi} \int_{\tan^{-1}(2/\sqrt{5})}^{\pi + \tan^{-1}(-2/\sqrt{5})} \int_0^{2 \csc \phi} f(x(\rho, \theta, \phi), y(\rho, \theta, \phi), z(\rho, \theta, \phi)) d\rho d\phi d\theta. \end{aligned}$$

31. The region is the volume below the conical surface and above the surface of the sphere:

Letting ϕ range from $\frac{3\pi}{4}$ to π with $0 \leq \rho \leq 4$ slices out a conical piece from the bottom of the sphere of radius 4. Since θ is constrained to $0 \leq \theta \leq \pi$, we want only the half of that piece that lies in the range $y \geq 0$. The cone, which has rectangular equation $z = -\sqrt{x^2 + y^2}$, meets the sphere when

$$x^2 + y^2 + z^2 = x^2 + y^2 + (x^2 + y^2) = 2(x^2 + y^2) = 16,$$

so it meets the sphere on a circle of radius $2\sqrt{2}$ in the plane $z = -2\sqrt{2}$. Then if we allow x to range from $-2\sqrt{2}$ to $2\sqrt{2}$, we can let y range from 0 to $\sqrt{8 - x^2}$ (since we want $y \geq 0$), and then z ranges from $-\sqrt{16 - x^2 - y^2}$ to $-\sqrt{x^2 + y^2}$. The integrand is $\rho^5 \cos \phi \sin \phi = \rho^3 \cos \phi \cdot \rho^2 \sin \phi$, so the integrand in rectangular coordinates is

$$\rho^3 \cos \phi = \rho^2 \cdot \rho \cos \phi = (x^2 + y^2 + z^2)z.$$

Therefore the integral becomes

$$\int_{-2\sqrt{2}}^{2\sqrt{2}} \int_0^{\sqrt{8-x^2}} \int_{-\sqrt{16-x^2-y^2}}^{-\sqrt{x^2+y^2}} (x^2 + y^2 + z^2)z \, dz \, dy \, dx.$$

32. The region is the volume enclosed by the surface shown together with its bounding planes:

Since $0 \leq \rho \leq 2$ and $\frac{\pi}{2} \leq \theta \leq \frac{3\pi}{2}$, the projection of this region onto the xy -plane will lie inside the semicircle of radius 2 in the second and third quadrants. Then $\frac{\pi}{2} \leq \phi \leq \pi$, so the region is the portion of the sphere of radius 2 lying below the second and third quadrants. In terms of rectangular coordinates, we get $-2 \leq x \leq 0$, and then $-\sqrt{4-x^2} \leq y \leq \sqrt{4-x^2}$, and finally $-\sqrt{4-x^2-y^2} \leq z \leq 0$. The integrand is

$$\frac{\rho^4 \sin \phi \cos \phi}{\rho^2 + 3} = \frac{\rho^2 \cos \phi}{\rho^2 + 3} \cdot \rho^2 \sin \phi.$$

So in rectangular coordinates, the integrand is

$$\frac{\rho^2 \cos \phi}{\rho^2 + 3} = \frac{\rho \cdot \rho \cos \phi}{\rho^2 + 3} = \frac{z \sqrt{x^2 + y^2 + z^2}}{x^2 + y^2 + z^2 + 3}.$$

Finally, the integral becomes

$$\int_{-2}^0 \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} \int_{-\sqrt{4-x^2-y^2}}^0 \frac{z \sqrt{x^2 + y^2 + z^2}}{x^2 + y^2 + z^2 + 3} dz dy dx.$$

33. The situation is:

We use a variant of the standard spherical coordinates in which x is parametrized with $x = \rho \cos \phi$; then $y = \rho \cos \theta \sin \phi$ and $z = \rho \sin \theta \sin \phi$. We do this so that the part of the sphere to the right of $x = 2$ is at the “top” of the re-parametrized sphere. Considering the portion to the right of $x = 2$, it is described first by $0 \leq \theta \leq \pi$. For any ϕ , we can determine the range of ρ from the following projection of the region onto the xz -plane:

For a given ϕ , the length of the diagonal line from the origin to the intersection with $x = 2$ is $2 \sec \phi$, so the range of integration (since we want the region to the right of $x = 2$) is $2 \sec \phi \leq \rho \leq 5$. The range for ϕ is from 0 to the point where the plane intersects the sphere; this is the point where $2 \sec \phi = 5$, or $\cos \phi = \frac{2}{5}$. So the integral is

$$\begin{aligned}
 \int_0^{\cos^{-1}(2/5)} \int_{2 \sec \phi}^5 \int_0^\pi \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi &= \pi \int_0^{\cos^{-1}(2/5)} \int_{2 \sec \phi}^5 \rho^2 \sin \phi \, d\rho \, d\phi \\
 &= \pi \int_0^{\cos^{-1}(2/5)} \left[\frac{1}{3} \rho^3 \sin \phi \right]_{2 \sec \phi}^5 d\phi \\
 &= \frac{\pi}{3} \int_0^{\cos^{-1}(2/5)} (125 \sin \phi - 8 \sec^3 \phi \sin \phi) \, d\phi \\
 &= \frac{\pi}{3} \int_0^{\cos^{-1}(2/5)} (125 \sin \phi - 8 \sec^2 \phi \tan \phi) \, d\phi \\
 &= \frac{\pi}{3} [-125 \cos \phi - 4 \sec^2 \phi]_0^{\cos^{-1}(2/5)}.
 \end{aligned}$$

Now, since $\sec^2 \phi = \frac{1}{\cos^2 \phi}$, evaluating this final result is not difficult:

$$\frac{\pi}{3} [-125 \cos \phi - 4 \sec^2 \phi]_0^{\cos^{-1}(2/5)} = \frac{\pi}{3} \left(\left(-125 \cdot \left(\frac{2}{5} \right) - 4 \left(\frac{5}{2} \right)^2 \right) - (-125 - 4) \right) = \boxed{18\pi}.$$

Since the volume of the entire hemisphere is $\frac{1}{2} \cdot \frac{4}{3} \pi r^3 = \frac{2}{3} \pi \cdot 5^3 = \frac{250}{3} \pi$, the volume of the piece to the left of $x = 2$ is $\frac{250}{3} \pi - 18\pi = \boxed{\frac{196}{3} \pi}$.

The volume we are looking for is the volume inside the large sphere but outside the inner surface; this is described by $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \pi$, and $1 + \cos \phi \leq \rho \leq 2$, so the volume it

$$\begin{aligned}
 V &= \int_0^\pi \int_{1+\cos \phi}^2 \int_0^{2\pi} \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi \\
 &= 2\pi \int_0^\pi \int_{1+\cos \phi}^2 \rho^2 \sin \phi \, d\rho \, d\phi \\
 &= 2\pi \int_0^\pi \left[\frac{1}{3} \rho^3 \sin \phi \right]_{1+\cos \phi}^2 d\phi \\
 &= \frac{2}{3} \pi \int_0^\pi (8 \sin \phi - (1 + \cos \phi)^3 \sin \phi) \, d\phi \\
 &= \frac{2}{3} \pi \left[-8 \cos \phi + \frac{1}{4} (1 + \cos \phi)^4 \right]_0^\pi \\
 &= \frac{2}{3} \pi (8 - (-8 + 4)) = \boxed{8\pi}.
 \end{aligned}$$

35. In spherical coordinates, the solid lying above the cone $\phi = \alpha$ and inside the sphere $\rho = a$ is defined by $0 \leq \rho \leq a$, $0 \leq \theta \leq 2\pi$, and $0 \leq \phi \leq \alpha$, so its volume is

$$\begin{aligned}
 \int_0^a \int_0^{2\pi} \int_0^\alpha \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho &= \int_0^a \int_0^{2\pi} [-\rho^2 \cos \phi]_0^\alpha \, d\theta \, d\rho \\
 &= (1 - \cos \alpha) \int_0^a \int_0^{2\pi} \rho^2 \, d\theta \, d\rho \\
 &= 2\pi(1 - \cos \alpha) \int_0^a \rho^2 \, d\rho \\
 &= 2\pi(1 - \cos \alpha) \left[\frac{1}{3} \rho^3 \right]_0^a = \boxed{\frac{2\pi}{3} a^3 (1 - \cos \alpha)}.
 \end{aligned}$$

36. This solid, since it lies in the first octant, is described by $b \leq \rho \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$, $0 \leq \phi \leq \frac{\pi}{2}$. The mass density at any point is

$$\frac{k}{\sqrt{x^2 + y^2 + z^2}} = \frac{k}{\rho},$$

where k is the constant of proportionality. Therefore the mass of the solid is

$$\begin{aligned}
 \int_b^a \int_0^{\pi/2} \int_0^{\pi/2} \frac{k}{\rho} \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho &= k \int_b^a \int_0^{\pi/2} \int_0^{\pi/2} \rho \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_b^a \int_0^{\pi/2} [-\rho \cos \phi]_0^{\pi/2} \, d\theta \, d\rho \\
 &= k \int_b^a \int_0^{\pi/2} \rho \, d\theta \, d\rho \\
 &= \frac{k\pi}{2} \int_b^a \rho \, d\rho \\
 &= \frac{k\pi}{2} \left[\frac{1}{2} \rho^2 \right]_b^a = \boxed{\frac{k\pi}{4} (a^2 - b^2)}.
 \end{aligned}$$

37. The mass density is $k(x^2 + y^2 + z^2) = k\rho^2$, where k is the constant of proportionality, so the mass of the ball is

$$\begin{aligned}
 \int_0^a \int_0^{2\pi} \int_0^\pi k\rho^2 \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho &= k \int_0^a \int_0^{2\pi} \int_0^\pi \rho^4 \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} [-\rho^4 \cos \phi]_0^\pi \, d\theta \, d\rho \\
 &= 2k \int_0^a \int_0^{2\pi} \rho^4 \, d\theta \, d\rho \\
 &= 4\pi k \int_0^a \rho^4 \, d\rho \\
 &= 4\pi k \left[\frac{1}{5} \rho^5 \right]_0^a = \boxed{\frac{4\pi}{5} ka^5}.
 \end{aligned}$$

38. The given solid lies below the plane $z = 1$ and above the half-cone $z = \sqrt{x^2 + y^2}$, which in spherical coordinates is

$$\rho \cos \phi = \sqrt{\rho^2 \cos^2 \theta \sin^2 \phi + \rho^2 \sin^2 \theta \sin^2 \phi} = \rho \sin \phi \sqrt{\cos^2 \theta + \sin^2 \theta} = \rho \sin \phi.$$

This is just the equation $\tan \phi = 1$, or $\phi = \frac{\pi}{4}$. So the integral to find the mass has bounds $0 \leq \phi \leq \frac{\pi}{4}$ and $0 \leq \theta \leq 2\pi$. For a given value of ϕ , the point of intersection with $z = 1$ is found by looking at the cross-section

The length ρ is such that $\cos \phi = \frac{1}{\rho}$, so that $\rho = \sec \phi$. The mass density function is $z\sqrt{x^2 + y^2 + z^2} =$

$\rho \cos \phi \cdot \rho = \rho^2 \cos \phi$. Therefore the mass of the solid is

$$\begin{aligned}
 \int_0^{\pi/4} \int_0^{2\pi} \int_0^{\sec \phi} \rho^2 \cos \phi \cdot \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi &= \int_0^{\pi/4} \int_0^{2\pi} \int_0^{\sec \phi} \rho^4 \sin \phi \cos \phi \, d\rho \, d\theta \, d\phi \\
 &= \int_0^{\pi/4} \int_0^{2\pi} \left[\frac{1}{5} \rho^5 \sin \phi \cos \phi \right]_0^{\sec \phi} d\theta \, d\phi \\
 &= \frac{1}{5} \int_0^{\pi/4} \int_0^{2\pi} \sec^4 \phi \sin \phi \, d\theta \, d\phi \\
 &= \frac{2\pi}{5} \int_0^{\pi/4} \sec^2 \phi \cdot \sec \phi \tan \phi \, d\phi \\
 &= \frac{2\pi}{5} \left[\frac{1}{3} \sec^3 \phi \right]_0^{\pi/4} = \boxed{\frac{2\pi}{15}(2\sqrt{2} - 1)}.
 \end{aligned}$$

39. Position the hemisphere so that its base is on the xy -plane and lies in the region $z \geq 0$. Then the mass density function is $k\sqrt{x^2 + y^2 + z^2} = k\rho$, where k is the constant of proportionality. Therefore both the solid and the mass density function are symmetric about the z -axis, so that by symmetry $\bar{x} = \bar{y} = 0$. It remains only to find $\bar{z}$. The mass M of the hemisphere is

$$\begin{aligned}
 \int_0^a \int_0^{2\pi} \int_0^{\pi/2} k\rho \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho &= k \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho^3 \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} [-\rho^3 \cos \phi]_0^{\pi/2} d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \rho^3 \, d\theta \, d\rho \\
 &= 2\pi k \int_0^a \rho^3 \, d\rho \\
 &= 2\pi k \left[\frac{1}{4} \rho^4 \right]_0^a = \frac{\pi}{2} k a^4.
 \end{aligned}$$

From Objective 4 in Section 14.6, the moment about the xy -plane, M_{xy} , is

$$\begin{aligned}
 \iiint_E z \delta(x, y, z) \, dV &= \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho \cos \phi \cdot k\rho \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho^4 \sin \phi \cos \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \left[\frac{1}{2} \rho^4 \sin^2 \phi \right]_0^{\pi/2} d\theta \, d\rho \\
 &= \frac{1}{2} k \int_0^a \int_0^{2\pi} \rho^4 \, d\theta \, d\rho \\
 &= \pi k \int_0^a \rho^4 \, d\rho \\
 &= \pi k \left[\frac{1}{5} \rho^5 \right]_0^a = \frac{\pi}{5} k a^5.
 \end{aligned}$$

Then the center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{M_{xy}}{M} \right) = \boxed{\left(0, 0, \frac{2a}{5} \right)}.$$

40. Position the hemisphere so that its base is on the xy -plane and lies in the region $z \geq 0$. Then the distance of (x, y, z) from the axis of symmetry, which is the z -axis, is $\sqrt{x^2 + y^2} = \rho \sin \phi$, so that the

mass density function is $k\rho \sin \phi$, where k is the constant of proportionality. Therefore both the solid and the mass density function are symmetric about the z -axis (since the mass density function does not depend on θ), so that by symmetry $\bar{x} = \bar{y} = 0$. It remains only to find $\bar{z}$. The mass M of the hemisphere is

$$\begin{aligned}
 \int_0^a \int_0^{2\pi} \int_0^{\pi/2} k\rho \sin \phi \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho &= k \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho^3 \sin^2 \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho^3 \left(\frac{1}{2} - \frac{1}{2} \cos(2\phi) \right) d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \left[\rho^3 \left(\frac{1}{2}\phi - \frac{1}{4} \sin(2\phi) \right) \right]_0^{\pi/2} d\theta \, d\rho \\
 &= \frac{\pi}{4} k \int_0^a \int_0^{2\pi} \rho^3 \, d\theta \, d\rho \\
 &= \frac{\pi^2}{2} k \int_0^a \rho^3 \, d\rho \\
 &= \frac{\pi^2}{2} k \left[\frac{1}{4} \rho^4 \right]_0^a = \frac{\pi^2}{8} k a^4.
 \end{aligned}$$

From Objective 4 in Section 14.6, the moment about the xy -plane, M_{xy} , is

$$\begin{aligned}
 \iiint_E z \delta(x, y, z) \, dV &= \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho \cos \phi \cdot k\rho \sin \phi \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho^4 \sin^2 \phi \cos \phi \, d\phi \, d\theta \, d\rho \\
 &= k \int_0^a \int_0^{2\pi} \left[\frac{1}{3} \rho^4 \sin^3 \phi \right]_0^{\pi/2} d\theta \, d\rho \\
 &= \frac{1}{3} k \int_0^a \int_0^{2\pi} \rho^4 \, d\theta \, d\rho \\
 &= \frac{2\pi}{3} k \int_0^a \rho^4 \, d\rho \\
 &= \frac{2\pi}{3} k \left[\frac{1}{5} \rho^5 \right]_0^a = \frac{2\pi}{15} k a^5.
 \end{aligned}$$

Then the center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{M_{xy}}{M} \right) = \boxed{\left(0, 0, \frac{16}{15\pi} a \right)}.$$

The half-cone $z = \sqrt{x^2 + y^2}$ is defined in spherical coordinates by

$$\rho \cos \phi = \sqrt{\rho^2 \cos^2 \theta \sin^2 \phi + \rho^2 \sin^2 \theta \sin^2 \phi} = \rho \sin \phi,$$

or $\tan \phi = 1$. Therefore the cone is defined by $\phi = \frac{\pi}{4}$. So the parametrization of the solid in spherical coordinates is $0 \leq \phi \leq \frac{\pi}{4}$, $0 \leq \theta \leq 2\pi$, $0 \leq \rho \leq 3$. By symmetry, $\bar{x} = \bar{y} = 0$, so it remains only to find $\bar{z}$. The solid is homogeneous, so we take its mass density to be a constant k . The mass M of the solid is then

$$\begin{aligned} \int_0^{\pi/4} \int_0^{2\pi} \int_0^3 k \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi &= k \int_0^{\pi/4} \int_0^{2\pi} \left[\frac{1}{3} \rho^3 \sin \phi \right]_0^3 d\theta \, d\phi \\ &= 9k \int_0^{\pi/4} \int_0^{2\pi} \sin \phi \, d\theta \, d\phi \\ &= 18\pi k \int_0^{\pi/4} \sin \phi \, d\phi \\ &= 18\pi k [-\cos \phi]_0^{\pi/4} = 9\pi k(2 - \sqrt{2}). \end{aligned}$$

From Objective 4 in Section 14.6, the moment about the xy -plane, M_{xy} , is

$$\begin{aligned} \iiint_E z \delta(x, y, z) \, dV &= \int_0^{\pi/4} \int_0^{2\pi} \int_0^3 k \rho \cos \phi \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi \\ &= k \int_0^{\pi/4} \int_0^{2\pi} \int_0^3 \rho^3 \sin \phi \cos \phi \, d\rho \, d\theta \, d\phi \\ &= k \int_0^{\pi/4} \int_0^{2\pi} \left[\frac{1}{4} \rho^4 \sin \phi \cos \phi \right]_0^3 d\theta \, d\phi \\ &= \frac{81}{4} k \int_0^{\pi/4} \int_0^{2\pi} \sin \phi \cos \phi \, d\theta \, d\phi \\ &= \frac{81}{2} \pi k \int_0^{\pi/4} \sin \phi \cos \phi \, d\phi \\ &= \frac{81}{2} \pi k \left[\frac{1}{2} \sin^2 \phi \right]_0^{\pi/4} = \frac{81}{8} \pi k. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{(81/8)\pi k}{9\pi k(2 - \sqrt{2})}\right) = \left(0, 0, \frac{9}{8(2 - \sqrt{2})}\right).$$

This can be simplified to $\boxed{\left(0, 0, \frac{9}{16}(2 + \sqrt{2})\right)}$ by rationalizing the denominator.

42. The solid is:

This solid is most easily modeled using cylindrical coordinates. We have $0 \leq \theta \leq \pi$ and $0 \leq r \leq 4$; for each $y = r \sin \theta$, z varies from 0 to $2y = 2r \sin \theta$. If the mass density of the solid is a constant k , then its mass M is

$$\begin{aligned} \int_0^\pi \int_0^4 \int_0^{2r \sin \theta} r \, dz \, dr \, d\theta &= \int_0^\pi \int_0^4 [rz]_0^{2r \sin \theta} \, dr \, d\theta \\ &= \int_0^\pi \int_0^4 2r^2 \sin \theta \, dr \, d\theta \\ &= \int_0^\pi \left[\frac{2}{3} r^3 \sin \theta \right]_0^4 \, d\theta \\ &= \frac{128}{3} \int_0^\pi \sin \theta \, d\theta \\ &= \frac{128}{3} [-\cos \theta]_0^\pi = \frac{256}{3}. \end{aligned}$$

By symmetry, $\bar{x} = 0$. From Objective 4 in Section 14.6, the remaining moments are

$$\begin{aligned}
 M_{xz} &= \iiint_E y \delta(x, y, z) \, dV \\
 &= \int_0^\pi \int_0^4 \int_0^{2r \sin \theta} r \sin \theta \cdot k \cdot r \, dz \, dr \, d\theta \\
 &= k \int_0^\pi \int_0^4 \int_0^{2r \sin \theta} r^2 \sin \theta \, dz \, dr \, d\theta \\
 &= k \int_0^\pi \int_0^4 [r^2 z \sin \theta]_0^{2r \sin \theta} \, dr \, d\theta \\
 &= k \int_0^\pi \int_0^4 2r^3 \sin^2 \theta \, dr \, d\theta \\
 &= k \int_0^\pi \left[\frac{1}{2} r^4 \sin^2 \theta \right]_0^4 \, d\theta \\
 &= k \int_0^\pi 128 \sin^2 \theta \, d\theta \\
 &= k \int_0^\pi (64 - 64 \cos(2\theta)) \, d\theta \\
 &= k [64\theta - 32 \sin(2\theta)]_0^\pi = 64k\pi
 \end{aligned}$$

$$\begin{aligned}
 M_{xy} &= \iiint_E z \delta(x, y, z) \, dV \\
 &= \int_0^\pi \int_0^4 \int_0^{2r \sin \theta} z \cdot k \cdot r \, dz \, dr \, d\theta \\
 &= k \int_0^\pi \int_0^4 \int_0^{2r \sin \theta} rz \, dz \, dr \, d\theta \\
 &= k \int_0^\pi \int_0^4 \left[\frac{1}{2} r z^2 \right]_0^{2r \sin \theta} \, dr \, d\theta \\
 &= k \int_0^\pi \int_0^4 2r^3 \sin^2 \theta \, dr \, d\theta \\
 &= 64k\pi,
 \end{aligned}$$

since the final integral is the same one as in the computation of M_{xz} . Therefore the center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(0, \frac{M_{xz}}{M}, \frac{M_{xy}}{M} \right) = \boxed{\left(0, \frac{3\pi}{4}, \frac{3\pi}{4} \right)}.$$

43. Parametrize the sphere using spherical coordinates, and compute the moment of inertia about the diameter that lies along the z -axis. The distance of any point in the solid from the z -axis is $\sqrt{x^2 + y^2} =$

$\rho \sin \phi$; letting the mass density be a constant δ , the moment of inertia is

$$\begin{aligned}
 I_z &= \iiint_E r^2 \delta(x, y, z) dV \\
 &= \int_0^\pi \int_0^2 \int_0^{2\pi} (\rho \sin \phi)^2 \cdot \delta \cdot \rho^2 \sin \phi d\theta d\rho d\phi \\
 &= \delta \int_0^\pi \int_0^2 \int_0^{2\pi} \rho^4 \sin^3 \phi d\theta d\rho d\phi \\
 &= 2\pi\delta \int_0^\pi \int_0^2 \rho^4 \sin^3 \phi d\rho d\phi \\
 &= 2\pi\delta \int_0^\pi \left[\frac{1}{5} \rho^5 \sin^3 \phi \right]_0^2 d\phi \\
 &= \frac{64}{5} \pi \delta \int_0^\pi \sin^3 \phi d\phi \\
 &= \frac{64}{5} \pi \delta \int_0^\pi (1 - \cos^2 \phi) \sin \phi d\phi \\
 &= \frac{64}{5} \pi \delta \left[-\cos \phi + \frac{1}{3} \cos^3 \phi \right]_0^\pi = \boxed{\frac{256}{15} \pi \delta}.
 \end{aligned}$$

44. Parametrize the sphere using spherical coordinates, and compute the moment of inertia about the diameter that lies along the z -axis. The distance of any point in the solid from the z -axis is $\sqrt{x^2 + y^2} = \rho \sin \phi$; letting the mass density be a constant δ , the moment of inertia is

$$\begin{aligned}
 I_z &= \iiint_E r^2 \delta(x, y, z) dV \\
 &= \int_0^\pi \int_0^a \int_0^{2\pi} (\rho \sin \phi)^2 \cdot \delta \cdot \rho^2 \sin \phi d\theta d\rho d\phi \\
 &= \delta \int_0^\pi \int_0^a \int_0^{2\pi} \rho^4 \sin^3 \phi d\theta d\rho d\phi \\
 &= 2\pi\delta \int_0^\pi \int_0^a \rho^4 \sin^3 \phi d\rho d\phi \\
 &= 2\pi\delta \int_0^\pi \left[\frac{1}{5} \rho^5 \sin^3 \phi \right]_0^a d\phi \\
 &= \frac{2}{5} a^5 \pi \delta \int_0^\pi \sin^3 \phi d\phi \\
 &= \frac{2}{5} a^5 \pi \delta \int_0^\pi (1 - \cos^2 \phi) \sin \phi d\phi \\
 &= \frac{2}{5} a^5 \pi \delta \left[-\cos \phi + \frac{1}{3} \cos^3 \phi \right]_0^\pi = \boxed{\frac{8}{15} a^5 \pi \delta}.
 \end{aligned}$$

45. The solid is symmetric about the z -axis, so that by symmetry $\bar{x} = \bar{y} = 0$. It remains only to find $\bar{z}$. The mass M of the hemisphere (which is assumed to have mass density k for some constant k) is half the volume of a sphere of radius a with mass density k , which is

$$M = \frac{1}{2} \cdot \frac{4}{3} \pi a^3 \cdot k = \frac{2}{3} \pi k a^3.$$

From Objective 4 in Section 14.6, the moment about the xy -plane, M_{xy} , is

$$\begin{aligned}
 \iiint_E z\delta(x, y, z) dV &= \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho \cos \phi \cdot k \cdot \rho^2 \sin \phi d\phi d\theta d\rho \\
 &= k \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \rho^3 \sin \phi \cos \phi d\phi d\theta d\rho \\
 &= k \int_0^a \int_0^{2\pi} \left[\frac{1}{2} \rho^3 \sin^2 \phi \right]_0^{\pi/2} d\theta d\rho \\
 &= \frac{1}{2} k \int_0^a \int_0^{2\pi} \rho^3 d\theta d\rho \\
 &= \pi k \int_0^a \rho^3 d\rho \\
 &= \pi k \left[\frac{1}{4} \rho^4 \right]_0^a = \frac{\pi}{4} k a^4.
 \end{aligned}$$

Then the center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{M_{xy}}{M} \right) = \boxed{\left(0, 0, \frac{3a}{8} \right)}.$$

46. Converting to spherical coordinates, we get

$$\begin{aligned}
 F &= k\delta \iiint_E \frac{\cos \phi}{\rho^2} dV = k\delta \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \frac{\cos \phi}{\rho^2} \cdot \rho^2 \sin \phi d\phi d\theta d\rho \\
 &= k\delta \int_0^a \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cos \phi d\phi d\theta d\rho \\
 &= k\delta \int_0^a \int_0^{2\pi} \left[\frac{1}{2} \sin^2 \phi \right]_0^{\pi/2} d\theta d\rho \\
 &= k\delta \int_0^a \int_0^{2\pi} \frac{1}{2} d\theta d\rho \\
 &= \boxed{\pi a k \delta}.
 \end{aligned}$$

47. (a) With $D(\rho) = D_0 e^{-k\rho}$, we know that $D(0) = D_0 e^{-k \cdot 0} = D_0 = 2500 \text{ kg/m}^3$, and it follows that $D(\rho) = 2500 e^{-k\rho}$. Next, the radius of Dione is 560 km, which is $5.6 \times 10^5 \text{ m}$; then we get $D(5.6 \times 10^5) = 2500 e^{-5.6 \times 10^5 k} = 1250$, so that $e^{-5.6 \times 10^5 k} = \frac{1}{2}$ and solving for k gives $k = \frac{-\ln 2}{5.6 \times 10^5} \approx 1.238 \times 10^{-6} \text{ m}^{-1}$. So $D(\rho) = 2500 e^{-1.238 \times 10^{-6} \rho}$.

(b) Modeling Dione as a sphere, the mass density is $D(\rho)$, so the mass of Dione is approximately

$$\begin{aligned}
 \int_0^{5.6 \times 10^5} \int_0^{2\pi} \int_0^\pi D(\rho) \rho^2 \sin \phi d\phi d\theta d\rho &= 2500 \int_0^{5.6 \times 10^5} \int_0^{2\pi} \int_0^\pi \rho^2 e^{-1.24 \times 10^{-6} \rho} \sin \phi d\phi d\theta d\rho \\
 &= 2500 \int_0^{5.6 \times 10^5} \int_0^{2\pi} \left[-\rho^2 e^{-1.24 \times 10^{-6} \rho} \cos \phi \right]_0^\pi d\theta d\rho \\
 &= 5000 \int_0^{5.6 \times 10^5} \int_0^{2\pi} \rho^2 e^{-1.24 \times 10^{-6} \rho} d\theta d\rho \\
 &= 10000\pi \int_0^{5.6 \times 10^5} \rho^2 e^{-1.24 \times 10^{-6} \rho} d\rho.
 \end{aligned}$$

Using Formulas 115 and 116 in the Table of Integrals, we get

$$\begin{aligned}
 & 10000\pi \int_0^{5.6 \times 10^5} \rho^2 e^{-1.24 \times 10^{-6} \rho} d\rho \\
 &= 10000\pi \left(\left[\frac{1}{-1.24 \times 10^{-6}} \rho^2 e^{-1.24 \times 10^{-6} \rho} \right]_0^{5.6 \times 10^5} \right. \\
 &\quad \left. - \frac{2}{-1.24 \times 10^{-6}} \int_0^{5.6 \times 10^5} \rho e^{-1.24 \times 10^{-6} \rho} d\rho \right) \\
 &\approx 10000\pi \left(-1.263 \times 10^{17} \right. \\
 &\quad \left. + \frac{2}{(1.24 \times 10^{-6})^3} \left[(-1.24 \times 10^{-6} \rho - 1) e^{-1.24 \times 10^{-6} \rho} \right]_0^{5.6 \times 10^5} \right) \\
 &\approx 10000\pi \left(-1.263 \times 10^{17} + 1.614 \times 10^{17} \right) \approx \boxed{1.103 \times 10^{21} \text{ kg}}.
 \end{aligned}$$

This is remarkably close to the measured mass. It differs from the measured mass by only 4.76%. The density model for the asteroid is reasonable.

48. If the density decrease is linear, then the density function is $D(\rho) = 2500 - \frac{1250}{5.6 \times 10^5} \rho$ kg/m³, and the mass is computed to be

$$\begin{aligned}
 & \int_0^{5.6 \times 10^5} \int_0^{2\pi} \int_0^\pi D(\rho) \rho^2 \sin \phi d\phi d\theta d\rho \\
 &= \int_0^{5.6 \times 10^5} \int_0^{2\pi} \int_0^\pi \left(2500 - \frac{1250}{5.6 \times 10^5} \rho \right) \rho^2 \sin \phi d\phi d\theta d\rho \\
 &= \int_0^{5.6 \times 10^5} \int_0^{2\pi} \left[- \left(2500 - \frac{1250}{5.6 \times 10^5} \rho \right) \rho^2 \cos \phi \right]_0^\pi d\theta d\rho \\
 &= 2 \int_0^{5.6 \times 10^5} \int_0^{2\pi} \left(2500 - \frac{1250}{5.6 \times 10^5} \rho \right) \rho^2 d\theta d\rho \\
 &= 4\pi \int_0^{5.6 \times 10^5} \left(2500 \rho^2 - \frac{1250}{5.6 \times 10^5} \rho^3 \right) d\rho \\
 &= 4\pi \left[\frac{2500}{3} \rho^3 - \frac{312.5}{5.6 \times 10^5} \rho^4 \right]_0^{5.6 \times 10^5} \\
 &\approx \boxed{1.149 \times 10^{21} \text{ kg}}.
 \end{aligned}$$

This is still reasonably close to the measured mass, though not as good an approximation as in the previous problem.

Challenge Problems

49. Parametrize the sphere using spherical coordinates, and consider the spherical cap shown. The flat bottom of the cap is in the plane $z = R - h$. For an angle ϕ , we can compute the bounds on ρ by considering the diagram

For a given ϕ , the length of the diagonal line from the origin to the intersection with $z = R - h$ is $(R - h) \sec \phi$, so the range of integration (since we want the region above $z = R - h$) is $(R - h) \sec \phi \leq \rho \leq R$. The range for ϕ is from 0 to the point where the plane intersects the sphere; this is the point where $(R - h) \sec \phi = R$, or $\cos \phi = \frac{R-h}{R}$. So the integral is

$$\begin{aligned}
 & \int_0^{\cos^{-1}((R-h)/R)} \int_{(R-h) \sec \phi}^R \int_0^{2\pi} \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi \\
 &= 2\pi \int_0^{\cos^{-1}((R-h)/R)} \int_{(R-h) \sec \phi}^R \rho^2 \sin \phi \, d\rho \, d\phi \\
 &= 2\pi \int_0^{\cos^{-1}((R-h)/R)} \left[\frac{1}{3} \rho^3 \sin \phi \right]_{(R-h) \sec \phi}^R d\phi \\
 &= \frac{2\pi}{3} \int_0^{\cos^{-1}((R-h)/R)} (R^3 \sin \phi - (R-h)^3 \sec^3 \phi \sin \phi) \, d\phi \\
 &= \frac{2\pi}{3} \int_0^{\cos^{-1}((R-h)/R)} (R^3 \sin \phi - (R-h)^3 \sec^2 \phi \tan \phi) \, d\phi \\
 &= \frac{2\pi}{3} \left[-R^3 \cos \phi - \frac{(R-h)^3}{2} \sec^2 \phi \right]_0^{\cos^{-1}((R-h)/R)}.
 \end{aligned}$$

Now, since $\sec^2 \phi = \frac{1}{\cos^2 \phi}$, we evaluate the final result as follows:

$$\begin{aligned}
 & \frac{2\pi}{3} \left[-R^3 \cos \phi - \frac{(R-h)^3}{2} \sec^2 \phi \right]_0^{\cos^{-1}((R-h)/R)} \\
 &= \frac{2\pi}{3} \left(\left(-R^3 \cdot \left(\frac{R-h}{R} \right) - \frac{(R-h)^3}{2} \left(\frac{R}{R-h} \right)^2 \right) - \left(-R^3 - \frac{(R-h)^3}{2} \right) \right) \\
 &= \frac{1}{3} \pi h^2 (3R - h).
 \end{aligned}$$

14.9 Change of Variables Using Jacobians

Concepts and Vocabulary

1. The Jacobian is the determinant $\begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix}$.
2. True. See the theorems Change in the Variables in a Double (and Triple) Integral.

Skill Building

3. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 1 & -1 \end{vmatrix} = \boxed{-2}.$$

4. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} = \boxed{1}.$$

5. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 4 & -1 \\ 3 & \frac{1}{2} \end{vmatrix} = \boxed{5}.$$

6. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 2u & -2v \\ 2u & 2v \end{vmatrix} = \boxed{8uv}.$$

7. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{v} & -\frac{u}{v^2} \\ 1 & 1 \end{vmatrix} = \frac{1}{v} + \frac{u}{v^2} = \boxed{\frac{u+v}{v^2}}.$$

8. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} e^u \cos v & -e^u \sin v \\ e^u \sin v & e^u \cos v \end{vmatrix} = e^{2u} \cos^2 v + e^{2u} \sin^2 v = \boxed{e^{2u}}.$$

9. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} ve^u & e^u \\ e^{-v} & -ue^{-v} \end{vmatrix} = -uve^{u-v} - e^{u-v} = \boxed{-(uv+1)e^{u-v}}.$$

10. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \cos v & -u \sin v \\ v \cos u & \sin u \end{vmatrix} = \boxed{\sin u \cos v + uv \cos u \sin v}.$$

11. The Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & 1 & 1 \\ 1 & 1 & -1 \\ 1 & -1 & -1 \end{vmatrix} = \boxed{-4}.$$

12. The Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 2 & 1 & 1 \\ 1 & 1 & -1 \\ 1 & -1 & 0 \end{vmatrix} = \boxed{-5}.$$

13. The Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & 1 & 0 \\ 0 & 1 & -1 \\ 1 & 0 & -1 \end{vmatrix} = \boxed{-2}.$$

14. The Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & 1 & 1 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{vmatrix} = \boxed{0}.$$

15. The Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & 0 & 0 \\ 0 & 2v & 0 \\ 0 & 0 & 3w^2 \end{vmatrix} = \boxed{6vw^2}.$$

16. The Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 3 & 3 & 0 \\ 1 & 0 & -1 \\ 2u & 0 & -2w \end{vmatrix} = \boxed{6(w - u)}.$$

17. The region R is:

The area of this region is

$$\iint_R 1 \, dA.$$

Using the indicated change of variables and solving for x and y gives $x = 3u$ and $y = 2v$, so that the Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 3 & 0 \\ 0 & 2 \end{vmatrix} = 6.$$

The line $y = 0$ gives the line $v = 0$ in the uv -plane, and $y = 4\sqrt{1 - \frac{x^2}{9}}$ gives the equation in the uv -plane $2v = 4\sqrt{1 - \frac{(3u)^2}{9}} = 4\sqrt{1 - u^2}$, or $v = 2\sqrt{1 - u^2}$. The region in the uv -plane is

Therefore the area is

$$\iint_R 1 \, dA = \int_{-1}^1 \int_0^{2\sqrt{1-u^2}} |6| \, dv \, du = 12 \int_{-1}^1 \sqrt{1-u^2} \, du.$$

From Formula 62 in the Table of Integrals, we get

$$12 \int_{-1}^1 \sqrt{1-u^2} \, du = 12 \left[\frac{u}{2} \sqrt{1-u^2} + \frac{1}{2} \sin^{-1} u \right]_{-1}^1 = \boxed{6\pi}.$$

18. Using the indicated change of variables and solving for x and y gives $x = u$ and $y = \frac{v}{x} = \frac{v}{u}$, so that the Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ -\frac{v}{u^2} & \frac{1}{u} \end{vmatrix} = \frac{1}{u}.$$

The line $y = x$ gives the line $\frac{v}{u} = u$, or $v = u^2$ in the uv -plane, and $y = 3x$ gives $v = 3u^2$. The curves $xy = 1$ and $xy = 3$ correspond to $v = 1$ and $v = 3$. The region in the uv -plane is

To find the area, we integrate first with respect to u and then with respect to v :

$$\iint_R 1 \, dA = \int_1^3 \int_{\sqrt{v/3}}^{\sqrt{v}} \left| \frac{1}{u} \right| \, du \, dv.$$

The integration bounds on the inner integral are both positive, so we can drop the absolute value signs,

giving

$$\begin{aligned}
 \int_1^3 \int_{\sqrt{v/3}}^{\sqrt{v}} \left| \frac{1}{u} \right| du dv &= \int_1^3 [\ln u]_{\sqrt{v/3}}^{\sqrt{v}} dv \\
 &= \int_1^3 \left(\frac{1}{2} \ln v - \frac{1}{2} \ln \frac{v}{3} \right) dv \\
 &= \int_1^3 \left(\frac{1}{2} \ln v - \frac{1}{2} \ln v + \frac{1}{2} \ln 3 \right) dv \\
 &= \left[\frac{1}{2} v \ln 3 \right]_1^3 = \boxed{\ln 3}.
 \end{aligned}$$

19. (a) The region R is

- (b) With the indicated change of variables, $2x - y = 0$ and $2x - y = 4$ become $u = 0$ and $u = 4$, while $x + y = 0$ and $x + y = 3$ become $v = 0$ and $v = 3$ respectively. The region $R^\#$ is

- (c) Solving the equations for x and y gives $x = \frac{v+u}{3}$ and $y = \frac{2v-u}{3}$. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{3} & \frac{1}{3} \\ -\frac{1}{3} & \frac{2}{3} \end{vmatrix} = \frac{1}{3}.$$

(d) The integral becomes

$$\begin{aligned}
 \iint_R x \, dA &= \iint_{R^\#} \frac{u+v}{3} \cdot \left| \frac{1}{3} \right| \, du \, dv \\
 &= \frac{1}{9} \int_0^3 \int_0^4 (u+v) \, du \, dv \\
 &= \frac{1}{9} \int_0^3 \left[\frac{1}{2}u^2 + uv \right]_0^4 \, dv \\
 &= \frac{1}{9} \int_0^3 (8 + 4v) \, dv \\
 &= \frac{1}{9} [8v + 2v^2]_0^3 = \boxed{\frac{14}{3}}.
 \end{aligned}$$

20. (a) The region R is

(b) With the indicated change of variables, $2x - y = 1$ and $2x - y = 3$ become $u = 1$ and $u = 3$, while $x + y = 1$ and $x + y = 2$ becomes $v = 1$ and $v = 2$ respectively. The region $R^\#$ is

(c) Solving the equations for x and y gives $x = \frac{v+u}{3}$ and $y = \frac{2v-u}{3}$. The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{3} & \frac{1}{3} \\ -\frac{1}{3} & \frac{2}{3} \end{vmatrix} = \frac{1}{3}.$$

(d) The integral becomes

$$\begin{aligned}
 \iint_R (x^2 + y^2) dA &= \iint_{R^\#} \left(\left(\frac{u+v}{3} \right)^2 + \left(\frac{2v-u}{3} \right)^2 \right) \cdot \left| \frac{1}{3} \right| du dv \\
 &= \frac{1}{27} \int_1^2 \int_1^3 ((u+v)^2 + (2v-u)^2) du dv \\
 &= \frac{1}{27} \int_1^2 \int_1^3 (2u^2 - 2uv + 5v^2) du dv \\
 &= \frac{1}{27} \int_1^2 \left[\frac{2}{3}u^3 - u^2v + 5uv^2 \right]_1^3 dv \\
 &= \frac{1}{27} \int_1^2 \left(\frac{52}{3} - 8v + 10v^2 \right) dv \\
 &= \frac{1}{27} \left[\frac{52}{3}v - 4v^2 + \frac{10}{3}v^3 \right]_1^2 \\
 &= \boxed{\frac{86}{81}}.
 \end{aligned}$$

21. (a) The region R is

(b) The three edges of the triangle are the lines $y = 1$, $x + y = 0$, and $x - y = 0$. Solving the given equations for x and y gives $x = \frac{u+v}{2}$ and $y = \frac{u-v}{2}$. Then $y = 1$ becomes $u - v = 2$, or $v = u - 2$, while $x + y = 0$ and $x - y = 0$ become $u = 0$ and $v = 0$ respectively. The region $R^\#$ is

(c) From the equations for x and y in part (b), the Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{vmatrix} = -\frac{1}{2}.$$

(d) The integral becomes

$$\begin{aligned}
 \iint_R xy \, dA &= \iint_{R^\#} \left(\frac{u+v}{2} \right) \left(\frac{u-v}{2} \right) \cdot \left| -\frac{1}{2} \right| \, dv \, du \\
 &= \frac{1}{8} \int_0^2 \int_{u-2}^0 (u^2 - v^2) \, dv \, du \\
 &= \frac{1}{8} \int_0^2 \left[u^2 v - \frac{1}{3} v^3 \right]_{u-2}^0 \, du \\
 &= \frac{1}{8} \int_0^2 \left(-u^2(u-2) + \frac{1}{3}(u-2)^3 \right) \, du \\
 &= \frac{1}{8} \int_0^2 \left(2u^2 - u^3 + \frac{1}{3}(u-2)^3 \right) \, du \\
 &= \frac{1}{8} \left[\frac{2}{3} u^3 - \frac{1}{4} u^4 + \frac{1}{12} (u-2)^4 \right]_0^2 \\
 &= \frac{1}{8} \left(\frac{16}{3} - 4 - \frac{4}{3} \right) = \boxed{0}.
 \end{aligned}$$

22. (a) The region R is the same as the region R in Problem 21.
 (b) The change of variables is the same as that in Problem 21, so the region $R^\#$ is the same as well, and the boundaries of the region are as well.
 (c) As in Problem 21, the Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{vmatrix} = -\frac{1}{2}.$$

(d) The integral becomes

$$\begin{aligned}
 \iint_R (x+y) \sin(x-y) \, dA &= \iint_{R^\#} u \sin v \cdot \left| -\frac{1}{2} \right| \, dv \, du \\
 &= \frac{1}{2} \int_0^2 \int_{u-2}^0 u \sin v \, dv \, du \\
 &= \frac{1}{2} \int_0^2 [-u \cos v]_{u-2}^0 \, du \\
 &= \frac{1}{2} \int_0^2 (u \cos(u-2) - u) \, du \\
 &= \frac{1}{2} \int_0^2 u \cos(u-2) \, du - \frac{1}{2} \int_0^2 u \, du.
 \end{aligned}$$

For the first integral, use integration by parts, with $t = u$ and $ds = \cos(u-2) \, du$. Then $dt = du$ and $s = \sin(u-2)$. Proceeding,

$$\begin{aligned}
 &= \frac{1}{2} \left([u \sin(u-2)]_0^2 - \int_0^2 \sin(u-2) \, du \right) - \frac{1}{2} \left[\frac{1}{2} u^2 \right]_0^2 \\
 &= \frac{1}{2} \left(0 - [-\cos(u-2)]_0^2 \right) - 1 \\
 &= -\frac{1}{2} (-1 + \cos(-2)) - 1 \\
 &= \boxed{-\frac{1}{2}(1 + \cos 2)}.
 \end{aligned}$$

23. The region R is

Solving the given change of variables for x and y gives $x = 4u$ and $y = 3v$. Then $9x^2 + 16y^2$ becomes $9(4u)^2 + 16(3v)^2 = 144u^2 + 144v^2 = 144$, which is just $u^2 + v^2 = 1$, so that $R^\#$ is the circle of radius 1 centered at the origin together with its interior. The Jacobian of the transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 4 & 0 \\ 0 & 3 \end{vmatrix} = 12.$$

Then the integral is

$$\iint_R (3x - 2y) dA = \iint_{R^\#} (12u - 6v) \cdot |12| dA = 72 \iint_{R^\#} (2u - v) dA.$$

To perform the integration, use polar coordinates in the uv -plane:

$$\begin{aligned} 72 \iint_{R^\#} (2u - v) dA &= 72 \int_0^1 \int_0^{2\pi} (2r \cos \theta - r \sin \theta) \cdot r dr d\theta \\ &= 72 \int_0^1 \int_0^{2\pi} r^2 (2 \cos \theta - \sin \theta) dr d\theta \\ &= 72 \int_0^2 [r^2 (2 \sin \theta + \cos \theta)]_0^{2\pi} dr \\ &= \boxed{0}. \end{aligned}$$

24. The region R , change of variables formula, and Jacobian are as in Problem 23. Also as in Problem 23, the region $R^\#$ is the circle of radius 1 centered at the origin, together with its interior. The integral is

$$\iint_R (x^2 - y) dA = \iint_{R^\#} (16u^2 - 3v) \cdot |12| dA = 12 \iint_{R^\#} (16u^2 - 3v) dA.$$

To perform the integration, use polar coordinates in the uv -plane:

$$\begin{aligned}
 12 \iint_{R^\#} (16u^2 - 3v) \, dA &= 12 \int_0^1 \int_0^{2\pi} (16r^2 \cos^2 \theta - 3r \sin \theta) \cdot r \, d\theta \, dr \\
 &= 12 \int_0^1 \int_0^{2\pi} \left(16r^3 \left(\frac{1}{2} + \frac{1}{2} \cos 2\theta \right) - 3r^2 \sin \theta \right) d\theta \, dr \\
 &= 12 \int_0^1 \int_0^{2\pi} (8r^3 + 8r^3 \cos 2\theta - 3r^2 \sin \theta) \, d\theta \, dr \\
 &= 12 \int_0^1 [8r^3 \theta + 4r^3 \sin 2\theta + 3r^2 \cos \theta]_0^{2\pi} \, dr \\
 &= 12 \int_0^1 16\pi r^3 \, dr \\
 &= 12 [4\pi r^4]_0^1 = \boxed{48\pi}.
 \end{aligned}$$

25. The solid E is

Solving the given change of variables for x , y , and z gives $x = 2u$, $y = 2v$, and $z = 3w$. Then $\frac{x^2}{4} + \frac{y^2}{4} + \frac{z^2}{9} = 1$ becomes $\frac{(2u)^2}{4} + \frac{(2v)^2}{4} + \frac{(3w)^2}{9} = 1$, which is just $u^2 + v^2 + w^2 = 1$, so that $E^\#$ is the sphere of radius 1 centered at the origin, together with its interior. The Jacobian of the transformation is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{vmatrix} = 12.$$

Then the integral is

$$\iiint_E (x+1) \, dA = \iiint_{E^\#} (2u+1) \cdot |12| \, dA = 12 \iiint_{E^\#} (2u+1) \, dA.$$

To perform the integration, use spherical coordinates:

$$\begin{aligned}
 12 \iiint_{E^\#} (2u + 1) dA &= 12 \int_0^1 \int_0^\pi \int_0^{2\pi} (2\rho \cos \theta \sin \phi + 1) \cdot \rho^2 \sin \phi d\theta d\phi d\rho \\
 &= 12 \int_0^1 \int_0^\pi \int_0^{2\pi} (2\rho^3 \cos \theta \sin^2 \phi + \rho^2 \sin \phi) d\theta d\phi d\rho \\
 &= 12 \int_0^1 \int_0^\pi [2\rho^3 \sin \theta \sin^2 \phi + \rho^2 \theta \sin \phi]_0^{2\pi} d\phi d\rho \\
 &= 12 \int_0^1 \int_0^\pi 2\pi \rho^2 \sin \phi d\phi d\rho \\
 &= 24\pi \int_0^1 [-\rho^2 \cos \phi]_0^\pi d\rho \\
 &= 24\pi \int_0^1 2\rho^2 d\rho \\
 &= 24\pi \left[\frac{2}{3} \rho^3 \right]_0^1 = \boxed{16\pi}.
 \end{aligned}$$

26. The solid E is

Solving the given change of variables for x , y , and z gives $x = 3u$, $y = 2v$, and $z = w$. Then $\frac{x^2}{9} + \frac{y^2}{4} + z^2 = 1$ becomes $\frac{(3u)^2}{9} + \frac{(2v)^2}{4} + w^2 = 1$, which is just $u^2 + v^2 + w^2 = 1$, so that $E^\#$ is the region bounded by the sphere of radius 1 centered at the origin. The Jacobian of the transformation is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 3 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{vmatrix} = 6.$$

Then the integral is

$$\iiint_E (x + 2y) dA = \iiint_{E^\#} (3u + 4v) \cdot |12| dA = 12 \iiint_{E^\#} (3u + 4v) dA.$$

To perform the integration, use spherical coordinates:

$$\begin{aligned}
 12 \iiint_{E^\#} (3u + 4v) dA &= 12 \int_0^1 \int_0^\pi \int_0^{2\pi} (3\rho \cos \theta \sin \phi + 4\rho \sin \theta \sin \phi) \cdot \rho^2 \sin \phi d\theta d\phi d\rho \\
 &= 12 \int_0^1 \int_0^\pi \int_0^{2\pi} (3\rho^3 \cos \theta \sin^2 \phi + 4\rho^3 \sin \theta \sin^2 \phi) d\theta d\phi d\rho \\
 &= 12 \int_0^1 \int_0^\pi [3\rho^3 \sin \theta \sin^2 \phi - 4\rho^3 \cos \theta \sin^2 \phi]_0^{2\pi} d\phi d\rho \\
 &= \boxed{0}.
 \end{aligned}$$

Applications and Extensions

27. (a) The region R is

- (b) Use the transformation $u = 2x - 3y$, $v = x + 2y$. Then the boundaries of $R^\#$ are $u = 0$ and $u = 1$, and $v = 0$ and $v = 3$, so this is a rectangular region:

- (c) Solve the transformation equations for x and y , giving $x = \frac{2}{7}u + \frac{3}{7}v$, $y = -\frac{1}{7}u + \frac{2}{7}v$. Then the integrand becomes

$$x^2 y = \left(\frac{2}{7}u + \frac{3}{7}v \right)^2 \left(-\frac{1}{7}u + \frac{2}{7}v \right) = \frac{1}{343} (18v^3 + 15uv^2 - 4u^2v - 4u^3).$$

The Jacobian of the transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{2}{7} & \frac{3}{7} \\ -\frac{1}{7} & \frac{2}{7} \end{vmatrix} = \frac{1}{7}.$$

Therefore the integral is

$$\iint_R x^2 y dA = \boxed{\iint_{R^\#} \left(\frac{2}{7}u + \frac{3}{7}v \right)^2 \left(-\frac{1}{7}u + \frac{2}{7}v \right) \frac{1}{7} dv du}.$$

(d) Evaluating the integral, we get

$$\begin{aligned}
 \iint_R x^2 y \, dA &= \iint_{R^\#} \left(\frac{2}{7}u + \frac{3}{7}v \right)^2 \left(-\frac{1}{7}u + \frac{2}{7}v \right) \frac{1}{7} \, dv \, du \\
 &= \frac{1}{2401} \int_0^1 \int_0^3 (18v^3 + 15uv^2 - 4u^2v - 4u^3) \, dv \, du \\
 &= \frac{1}{2401} \int_0^1 \left[\frac{9}{2}v^4 + 5uv^3 - 2u^2v^2 - 4u^3v \right]_0^3 \, du \\
 &= \frac{1}{2401} \int_0^1 \left(\frac{729}{2} + 135u - 18u^2 - 12u^3 \right) \, du \\
 &= \frac{1}{2401} \left[\frac{729}{2}u + \frac{135}{2}u^2 - 6u^3 - 3u^4 \right]_0^1 \\
 &= \boxed{\frac{423}{2401}}.
 \end{aligned}$$

28. (a) The region R is

(b) Use the transformation $u = \frac{x}{3}$, $v = \frac{y}{4}$, so that $x = 3u$ and $y = 4v$. The equation in the uv -coordinate system is then $\frac{(3u)^2}{9} + \frac{(4v)^2}{16} = u^2 + v^2 = 1$, so it is the region bounded by the circle of radius 1 centered at the origin:

(c) The integrand becomes $x = 3u$, and the Jacobian of the transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 3 & 0 \\ 0 & 4 \end{vmatrix} = 12.$$

Therefore the integral is

$$\iint_R x \, dA = \iint_{R^\#} 3u \cdot |12| \, dA = \boxed{36 \iint_{R^\#} u \, dA}.$$

(d) Evaluating the integral using polar coordinates, we get

$$36 \iint_{R^\#} u \, dA = 36 \int_0^1 \int_0^{2\pi} r \cos \theta \cdot r \, d\theta \, dr = 36 \int_0^1 [r^2 \sin \theta]_0^{2\pi} \, dr = \boxed{0}.$$

29. (a) The region R is

(b) Use the transformation $u = x$, $v = xy$, so that $x = u$ and $y = \frac{v}{x} = \frac{v}{u}$. Then $xy = 1$ and $xy = 3$ becomes $v = 1$ and $v = 3$, while $x = 1$ and $x = 3$ become $u = 1$ and $u = 3$. So $R^\#$ is a square region:

- (c) The integrand becomes $x \cos(xy) = u \cos v$, and the Jacobian of the transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ -\frac{v}{u^2} & \frac{1}{u} \end{vmatrix} = \frac{1}{u}.$$

Therefore the integral is

$$\iint_R x \cos(xy) dA = \iint_{R^\#} u \cos v \cdot \frac{1}{u} dA = \iint_{R^\#} \cos v dA = \boxed{\int_1^3 \int_1^3 \cos v dv du}.$$

- (d) Evaluating the integral we get

$$\int_1^3 \int_1^3 \cos v du dv = 2 \int_1^3 \cos v dv = 2 [\sin v]_1^3 = \boxed{2(\sin 3 - \sin 1)}.$$

30. (a) The region R is the same as the region in Problem 29.
 (b) Use the same transformation as in Problem 29, giving the same region $R^\#$.
 (c) The integrand becomes $ye^{xy} = \frac{v}{u}e^v$, and the Jacobian of the transformation is, as in Problem 29, $\frac{1}{u}$. Therefore the integral is

$$\iint_R ye^{xy} dA = \iint_{R^\#} \frac{v}{u}e^v \cdot \frac{1}{u} dA = \boxed{\iint_{R^\#} \frac{v}{u^2}e^v dA}.$$

- (d) Evaluating the integral we get

$$\begin{aligned} \iint_{R^\#} \frac{v}{u^2}e^v dA &= \int_1^3 \int_1^3 \frac{v}{u^2}e^v du dv \\ &= \int_1^3 \left[-\frac{v}{u}e^v \right]_1^3 dv \\ &= \int_1^3 \left(ve^v - \frac{1}{3}ve^v \right) dv \\ &= \frac{2}{3} \int_1^3 ve^v dv. \end{aligned}$$

Now use Formula 115 in the Table of Integrals:

$$\begin{aligned} &= \frac{2}{3} [(v-1)e^v]_1^3 \\ &= \frac{2}{3} \cdot 2e^3 = \boxed{\frac{4}{3}e^3}. \end{aligned}$$

31. The region R is

These four equations may be rewritten $y - 3x = 0$, $y - 3x = 2$, $2y + x = 0$, and $2y + x = 10$. This suggests the transformations $u = y - 3x$ and $v = 2y + x$. Solving these for x and y gives $x = -\frac{2}{7}u + \frac{1}{7}v$ and $y = \frac{1}{7}u + \frac{3}{7}v$. With these transformation, the region $R^\#$ is the rectangular region bounded by $u = 0$, $u = 2$, $v = 0$, and $v = 10$. The Jacobian of this transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} -\frac{2}{7} & \frac{1}{7} \\ \frac{1}{7} & \frac{3}{7} \end{vmatrix} = -\frac{1}{7}.$$

The area of the region is therefore

$$\iint_R 1 \, dA = \iint_{R^\#} \left| -\frac{1}{7} \right| dA = \frac{1}{7} \iint_{R^\#} 1 \, dA = \frac{1}{7} \cdot 20 = \boxed{\frac{20}{7} \text{ square units}}$$

since the area of the rectangle is 20 square units.

32. The region R is

The given equations suggest the transformations $u = x + y$ and $v = y - 2x$. With these transformation, the region $R^\#$ is the rectangular region bounded by $u = -3$, $u = 1$, $v = 0$, and $v = 4$. Solving for x and y gives $x = \frac{1}{3}u - \frac{1}{3}v$ and $y = \frac{2}{3}u + \frac{1}{3}v$. Therefore the Jacobian of this transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{3} & -\frac{1}{3} \\ \frac{2}{3} & \frac{1}{3} \end{vmatrix} = \frac{1}{3}.$$

The area of the region is therefore

$$\iint_R 1 \, dA = \iint_{R^\#} \left| \frac{1}{3} \right| dA = \frac{1}{3} \iint_{R^\#} 1 \, dA = \frac{1}{3} \cdot 16 = \boxed{\frac{16}{3} \text{ square units}}$$

since the area of the rectangle is 16 square units.

33. The given equations suggest the transformations

$$u = x + 2y, \quad v = y - z, \quad w = z.$$

With these transformations, the solid $E^\#$ is the rectangular solid bounded by the planes $u = 0$, $u = 3$, $v = 0$, $v = 2$, $w = 0$, and $w = 6$, so that it has a volume of $3 \cdot 2 \cdot 6 = 36$ cubic units. Solving the transformation equations for x , y , and z gives $x = u - 2v - 2w$, $y = v + w$, and $z = w$. Therefore the Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & -2 & -2 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{vmatrix} = 1.$$

So the volume of E is

$$\iiint_E 1 \, dV = \iiint_{E^\#} 1 \, dV = 1 \cdot 36 = \boxed{36 \text{ cubic units}}.$$

34. The given equations suggest the transformations

$$u = x - y, \quad v = z - 2x, \quad w = z.$$

With these transformations, the solid $E^\#$ is the rectangular solid bounded by the planes $u = 0$, $u = 3$, $v = 0$, $v = 4$, $w = 1$, and $w = 5$, so that it has a volume of $3 \cdot 4 \cdot 4 = 48$ cubic units. Solving the transformation equations for x , y , and z gives $x = \frac{1}{2}w - \frac{1}{2}v$, $y = -u + \frac{1}{2}w - \frac{1}{2}v$, and $z = w$. Therefore the Jacobian is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 0 & -\frac{1}{2} & \frac{1}{2} \\ -1 & -\frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 1 \end{vmatrix} = -\frac{1}{2}.$$

So the volume of E is

$$\iiint_E 1 \, dV = \iiint_{E^\#} \left| -\frac{1}{2} \right| dV = \frac{1}{2} \cdot 48 = \boxed{24 \text{ cubic units}}.$$

35. With the given change of variables, the plane
- $z = 1$
- becomes the plane
- $w = 1$
- , and the paraboloid becomes

$$w = 9 - (3u \cos v)^2 - 9(u \sin v)^2 = 9 - 9u^2 \cos^2 v - 9u^2 \sin^2 v = 9 - 9u^2.$$

The trace of the surface of the solid in the xy -plane is the ellipse $x^2 + 9y^2 = 9$, so that $0 \leq u \leq 1$ and $0 \leq v \leq 2\pi$; $z = w$ ranges from 1 to $9 - 9u^2$. The Jacobian of the transformation is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 3 \cos v & -3u \sin v & 0 \\ \sin v & u \cos v & 0 \\ 0 & 0 & 1 \end{vmatrix} = 3u.$$

Therefore the volume of the solid is

$$\begin{aligned} \iint_E 1 \, dA &= \int_0^1 \int_0^{2\pi} \int_1^{9-9u^2} 3u \, dw \, dv \, du \\ &= \int_0^1 \int_0^{2\pi} [3uw]_1^{9-9u^2} \, dv \, du \\ &= \int_0^1 \int_0^{2\pi} (3u(9-9u^2) - 3u) \, dv \, du \\ &= \int_0^1 \int_0^{2\pi} (-27u^3 + 24u) \, dv \, du \\ &= 2\pi \int_0^1 (-27u^3 + 24u) \, du \\ &= 2\pi \left[-\frac{27}{4}u^4 + 12u^2 \right]_0^1 = \boxed{\frac{21}{2}\pi \text{ cubic units}}. \end{aligned}$$

36. Solving the transformation for x , y , and z gives $x = 2u$, $y = 3v$, $z = w$, and the ellipsoid becomes

$$\frac{(2u)^2}{4} + \frac{(3v)^2}{9} + w^2 = u^2 + v^2 + w^2 = 1.$$

Since $w = z$, we are considering only the portion of that region above the uv -plane. So the transformed solid $E^\#$ is the upper hemispherical half of the solid bounded by sphere of radius 1, which has volume $\frac{2}{3}\pi$ cubic units. The Jacobian of the transformation is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 1 \end{vmatrix} = 6.$$

Therefore the volume of E is

$$\iiint_E 1 \, dV = \iiint_{E^\#} 6 \, dV = 6 \cdot \frac{2}{3}\pi = \boxed{4\pi \text{ cubic units}}.$$

37. The transformation from rectangular to spherical coordinates is given by

$$x = \rho \cos \theta \sin \phi, \quad y = \rho \sin \theta \sin \phi, \quad z = \rho \cos \phi,$$

so that the Jacobian of the transformation is

$$\begin{aligned} \frac{\partial(x, y, z)}{\partial(\rho, \theta, \phi)} &= \begin{vmatrix} \frac{\partial x}{\partial \rho} & \frac{\partial x}{\partial \theta} & \frac{\partial x}{\partial \phi} \\ \frac{\partial y}{\partial \rho} & \frac{\partial y}{\partial \theta} & \frac{\partial y}{\partial \phi} \\ \frac{\partial z}{\partial \rho} & \frac{\partial z}{\partial \theta} & \frac{\partial z}{\partial \phi} \end{vmatrix} = \begin{vmatrix} \cos \theta \sin \phi & -\rho \sin \theta \sin \phi & \rho \cos \theta \cos \phi \\ \sin \theta \sin \phi & \rho \cos \theta \sin \phi & \rho \sin \theta \cos \phi \\ \cos \phi & 0 & -\rho \sin \phi \end{vmatrix} \\ &= \cos \phi \begin{vmatrix} -\rho \sin \theta \sin \phi & \rho \cos \theta \cos \phi \\ \rho \cos \theta \sin \phi & \rho \sin \theta \cos \phi \end{vmatrix} - \rho \sin \phi \begin{vmatrix} \cos \theta \sin \phi & -\rho \sin \theta \sin \phi \\ \sin \theta \sin \phi & \rho \cos \theta \sin \phi \end{vmatrix} \\ &= \cos \phi (-\rho^2 \sin^2 \theta \sin \phi \cos \phi - \rho^2 \cos^2 \theta \sin \phi \cos \phi) - \rho \sin \phi (\rho \cos^2 \theta \sin^2 \phi + \rho \sin^2 \theta \sin^2 \phi) \\ &= \cos \phi (-\rho^2 \sin \phi \cos \phi) - \rho \sin \phi (\rho \sin^2 \phi) \\ &= -\rho^2 (\sin \phi \cos^2 \phi + \sin^3 \phi) \\ &= -\rho^2 \sin \phi (\cos^2 \phi + \sin^2 \phi) \\ &= -\rho^2 \sin \phi. \end{aligned}$$

Note that $\rho^2 \geq 0$, and since $0 \leq \phi \leq \pi$, we also have $\sin \phi \geq 0$, so that $|\rho^2 \sin \phi| = \rho^2 \sin \phi$. Therefore

$$\begin{aligned} \iiint_E f(x, y, z) \, dV &= \iiint_{E^\#} f(\rho \sin \phi \cos \theta, \rho \sin \phi \sin \theta, \rho \cos \phi) \cdot |\rho^2 \sin \phi| \, dV \\ &= \iiint_{E^\#} f(\rho \sin \phi \cos \theta, \rho \sin \phi \sin \theta, \rho \cos \phi) \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi. \end{aligned}$$

Challenge Problems

38. (a) The region R is

(b) Use the transformation $u = xy$ and $v = \frac{y}{\sqrt{x}}$. To solve for x and y , note that we have

$$y = \frac{u}{x} = v\sqrt{x},$$

so that $x^{3/2} = \frac{u}{v}$ and therefore $x = u^{2/3}v^{-2/3}$. Then $u = xy$ gives $y = u^{1/3}v^{2/3}$. The transformed region $R^\#$ is the rectangular region bounded by $u = 2$ and $u = 5$, and by $v = \frac{y}{\sqrt{x}} = 1$ and $v = 3$.

(c) The Jacobian of the transformation is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{2}{3}u^{-1/3}v^{-2/3} & -\frac{2}{3}u^{2/3}v^{-5/3} \\ \frac{1}{3}u^{-2/3}v^{2/3} & \frac{2}{3}u^{1/3}v^{-1/3} \end{vmatrix} = \frac{4}{9v} + \frac{2}{9v} = \frac{2}{3v}.$$

Therefore the area of R is

$$\begin{aligned} \iint_R 1 \, dV &= \iint_{R^\#} \frac{2}{3v} \, dv \, du \\ &= \int_2^5 \int_1^3 \frac{2}{3v} \, dv \, du \\ &= \int_2^5 \left[\frac{2}{3} \ln v \right]_1^3 \, du \\ &= \int_2^5 \frac{2}{3} \ln 3 \, du = \boxed{2 \ln 3 \text{ square units}}. \end{aligned}$$

Review Exercises

1. In this iterated integral, first we integrate partially with respect to x :

$$\begin{aligned}\int_0^1 \int_1^e \frac{y}{x} dx dy &= \int_0^1 y \cdot [\ln x]_1^e dy = \int_0^1 y \cdot (\ln e - \ln 1) dy \\ &= \int_0^1 y \cdot (1 - 0) dy = \int_0^1 y dy = \left[\frac{y^2}{2} \right]_0^1 = \frac{1}{2} - 0 = \boxed{\frac{1}{2}}.\end{aligned}$$

2. In this iterated integral, first we integrate partially with respect to y :

$$\begin{aligned}\int_1^3 \int_3^6 (x^2 + y^2) dy dx &= \int_1^3 \left[x^2 y + \frac{y^3}{3} \right]_3^6 dx = \int_1^3 [(6x^2 + 72) - (3x^2 + 9)] dx \\ &= \int_1^3 (3x^2 + 63) dx = [x^3 + 63x]_1^3 = (27 + 189) - (1 + 63) = \boxed{152}.\end{aligned}$$

3. We begin by graphing the region R associated with the integral $\int_0^1 \int_y^1 ye^{-x^3} dx dy$: it is the region between the graphs of $x = y$ and $x = 1$, where $0 \leq y \leq 1$; see the figure. Observe that R is also an x -simple region: y varies from $y = 0$ to $y = x$, where $0 \leq x \leq 1$. Then according to Fubini's Theorem,

$$\begin{aligned}\int_0^1 \int_y^1 ye^{-x^3} dx dy &= \int_0^1 \int_0^x ye^{-x^3} dy dx = \int_0^1 e^{-x^3} \left[\frac{y^2}{2} \right]_0^x dx \\ &= \int_0^1 e^{-x^3} \left(\frac{x^2}{2} - 0 \right) dx = \frac{1}{2} \int_0^1 e^{-x^3} \cdot x^2 dx.\end{aligned}$$

To evaluate this integral, we make a substitution $u = -x^3$; then $du = -3x^2 dx$, so $x^2 dx = \frac{du}{-3}$. We also change the limits of integration: if $x = 0$, then $u = -0^3 = 0$; if $x = 1$, then $u = -1^3 = -1$. So

$$\begin{aligned}\frac{1}{2} \int_0^1 e^{-x^3} \cdot x^2 dx &= \frac{1}{2} \int_0^{-1} e^u \cdot \left(\frac{du}{-3} \right) = -\frac{1}{6} \int_0^{-1} e^u du \\ &= \frac{1}{6} \int_{-1}^0 e^u du = \frac{1}{6} [e^u]_{-1}^0 = \frac{1}{6} (e^0 - e^{-1}) = \frac{1}{6} \left(1 - \frac{1}{e} \right) = \boxed{\frac{e-1}{6e}}.\end{aligned}$$

4. In this iterated integral, first we integrate partially with respect to y :

$$\begin{aligned}
 \int_0^1 \int_0^{\sqrt{1+x^2}} \frac{1}{x^2 + y^2 + 1} dy dx &= \int_0^1 \int_0^{\sqrt{1+x^2}} \frac{1}{(1+x^2) + y^2} dy dx \\
 &= \int_0^1 \left[\frac{1}{\sqrt{1+x^2}} \tan^{-1} \left(\frac{y}{\sqrt{1+x^2}} \right) \right]_0^{\sqrt{1+x^2}} dx \\
 &= \int_0^1 \frac{1}{\sqrt{1+x^2}} \left[\tan^{-1} \left(\frac{\sqrt{1+x^2}}{\sqrt{1+x^2}} \right) - \tan^{-1} \left(\frac{0}{\sqrt{1+x^2}} \right) \right] dx \\
 &= \int_0^1 \frac{1}{\sqrt{1+x^2}} (\tan^{-1} 1 - \tan^{-1} 0) dx \\
 &= \int_0^1 \frac{1}{\sqrt{1+x^2}} \left(\frac{\pi}{4} - 0 \right) dx = \frac{\pi}{4} \int_0^1 \frac{1}{\sqrt{1+x^2}} dx.
 \end{aligned}$$

To evaluate this integral, we make a substitution $x = \tan \theta$, where $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$; then $dx = \sec^2 \theta d\theta$. We also change the limits of integration: if $x = 0$, then $0 = \tan \theta$, so $\theta = 0$; if $x = 1$, then $1 = \tan \theta$, so $\theta = \frac{\pi}{4}$. The radical in the integrand simplifies as $\sqrt{1+x^2} = \sqrt{1+\tan^2 \theta} = \sqrt{\sec^2 \theta} = \sec \theta$, where we used the fact that $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$ and so $\sec \theta > 0$. So the integral transforms into

$$\begin{aligned}
 \frac{\pi}{4} \int_0^1 \frac{1}{\sqrt{1+x^2}} dx &= \frac{\pi}{4} \int_0^{\pi/4} \frac{1}{\sec \theta} \cdot \sec^2 \theta d\theta = \frac{\pi}{4} \int_0^{\pi/4} \sec \theta d\theta = \frac{\pi}{4} [\ln |\sec \theta + \tan \theta|]_0^{\pi/4} \\
 &= \frac{\pi}{4} (\ln |\sec \frac{\pi}{4} + \tan \frac{\pi}{4}| - \ln |\sec 0 + \tan 0|) = \frac{\pi}{4} (\ln |\sqrt{2} + 1| - \ln |1 + 0|) \\
 &= \frac{\pi}{4} (\ln (\sqrt{2} + 1) - \ln 1) = \boxed{\frac{\pi \ln (\sqrt{2} + 1)}{4}}.
 \end{aligned}$$

5. In this iterated integral, first we integrate partially with respect to y :

$$\begin{aligned}
 \int_0^{\pi/4} \int_0^{\tan x} \sec x dy dx &= \int_0^{\pi/4} \sec x \cdot [y]_0^{\tan x} dx = \int_0^{\pi/4} \sec x \cdot (\tan x - 0) dx \\
 &= \int_0^{\pi/4} \sec x \tan x dx = [\sec x]_0^{\pi/4} = \sec \left(\frac{\pi}{4} \right) - \sec 0 = \boxed{\sqrt{2} - 1}.
 \end{aligned}$$

6. In this iterated integral, first we integrate partially with respect to y :

$$\begin{aligned}
 \int_0^1 \int_{-x}^x e^{x+y} dy dx &= \int_0^1 \int_{-x}^x e^x e^y dy dx = \int_0^1 e^x [e^y]_{-x}^x dx = \int_0^1 e^x (e^x - e^{-x}) dx \\
 &= \int_0^1 (e^{2x} - 1) dx = \left[\frac{1}{2} e^{2x} - x \right]_0^1 = \left(\frac{1}{2} e^2 - 1 \right) - \left(\frac{1}{2} e^0 - 0 \right) \\
 &= \frac{1}{2} e^2 - 1 - \frac{1}{2} = \frac{1}{2} e^2 - \frac{3}{2} = \boxed{\frac{e^2 - 3}{2}}.
 \end{aligned}$$

7. (a) Let $f(x, y) = x + 2y$, and let R be the closed square region defined by $0 \leq x \leq 4$, $-2 \leq y \leq 2$. Partition R into four congruent subsquares with sides $\Delta x_i = 2$, $i = 1, 2$, and $\Delta y_j = 2$, $j = 1, 2$, each with area $\Delta A_k = 4$. Choose (u_k, v_k) , $k = 1, 2, 3, 4$, as the center of the k th subsquare: $(u_1, v_1) = (1, -1)$, $(u_2, v_2) = (3, -1)$, $(u_3, v_3) = (1, 1)$, and $(u_4, v_4) = (3, 1)$. See figure (a) below.

Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^4 f(u_k, v_k) \Delta A_k &= f(1, -1) \cdot 4 + f(3, -1) \cdot 4 + f(1, 1) \cdot 4 + f(3, 1) \cdot 4 \\
 &= [f(1, -1) + f(3, -1) + f(1, 1) + f(3, 1)] \cdot 4 \\
 &= (-1 + 1 + 3 + 5) \cdot 4 = \boxed{32}.
 \end{aligned}$$

(a)

(b)

(c)

- (b) Since $f(x, y) = x + 2y$ is increasing with respect to both x and y , the greatest value of the function on each subsquare is attained at its upper-right corner and the smallest value of the function on each subsquare is attained at its lower-left corner.

To find the largest possible Riemann sum (for these subsquares), choose (u_k, v_k) , $k = 1, 2, 3, 4$, as the upper-right corner of the k th subsquare: $(u_1, v_1) = (2, 0)$, $(u_2, v_2) = (4, 0)$, $(u_3, v_3) = (2, 2)$, and $(u_4, v_4) = (4, 2)$. See figure (b) above. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^4 f(u_k, v_k) \Delta A_k &= f(2, 0) \cdot 4 + f(4, 0) \cdot 4 + f(2, 2) \cdot 4 + f(4, 2) \cdot 4 \\
 &= [f(2, 0) + f(4, 0) + f(2, 2) + f(4, 2)] \cdot 4 \\
 &= (2 + 4 + 6 + 8) \cdot 4 = \boxed{80}.
 \end{aligned}$$

To find the smallest possible Riemann sum (for these subsquares), choose (u_k, v_k) , $k = 1, 2, 3, 4$, as the lower-left corner of the k th subsquare: $(u_1, v_1) = (0, -2)$, $(u_2, v_2) = (2, -2)$, $(u_3, v_3) = (0, 0)$, and $(u_4, v_4) = (2, 0)$. See figure (c) above. Then the corresponding Riemann sum is:

$$\begin{aligned}
 \sum_{k=1}^4 f(u_k, v_k) \Delta A_k &= f(0, -2) \cdot 4 + f(2, -2) \cdot 4 + f(0, 0) \cdot 4 + f(2, 0) \cdot 4 \\
 &= [f(0, -2) + f(2, -2) + f(0, 0) + f(2, 0)] \cdot 4 \\
 &= (-4 - 2 + 0 + 2) \cdot 4 = \boxed{-16}.
 \end{aligned}$$

The average of these two values is $\frac{80 + (-16)}{2} = \frac{64}{2} = \boxed{32}$.

- (c) The actual value of the double integral $\iint_R f(x, y) dA$ can be found by applying Fubini's Theorem for rectangular regions:

$$\begin{aligned}
 \iint_R f(x, y) dA &= \int_0^4 \int_{-2}^2 (x + 2y) dy dx = \int_0^4 [xy + y^2]_{-2}^2 dx \\
 &= \int_0^4 [(2x + 4) - (-2x + 4)] dx = \int_0^4 4x dx = [2x^2]_0^4 = 32 - 0 = \boxed{32}.
 \end{aligned}$$

8. Using Fubini's Theorem, the given double integral $\iint_R x e^y dA$, where R is the closed rectangular region defined by $0 \leq x \leq 2$, $0 \leq y \leq 1$, equals either of the iterated integrals:

$$\int_0^2 \int_0^1 x e^y dy dx \quad \text{or} \quad \int_0^1 \int_0^2 x e^y dx dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x :

$$\begin{aligned} \iint_R x e^y dA &= \int_0^1 \int_0^2 x e^y dx dy = \int_0^1 e^y \left[\frac{x^2}{2} \right]_0^2 dy \\ &= \int_0^1 e^y (2 - 0) dy = 2 \int_0^1 e^y dy = 2 [e^y]_0^1 = 2(e^1 - e^0) = \boxed{2(e - 1)}. \end{aligned}$$

9. Using Fubini's Theorem, the given double integral $\iint_R \sin x \cos y dA$, where R is the closed rectangular region defined by $0 \leq x \leq \frac{\pi}{2}$, $0 \leq y \leq \frac{\pi}{3}$, equals either of the iterated integrals:

$$\int_0^{\pi/2} \int_0^{\pi/3} \sin x \cos y dy dx \quad \text{or} \quad \int_0^{\pi/3} \int_0^{\pi/2} \sin x \cos y dx dy.$$

Using the latter iterated integral, we begin by integrating partially with respect to x :

$$\begin{aligned} \iint_R \sin x \cos y dA &= \int_0^{\pi/3} \int_0^{\pi/2} \sin x \cos y dx dy = \int_0^{\pi/3} \cos y \cdot [-\cos x]_0^{\pi/2} dy \\ &= \int_0^{\pi/3} \cos y \cdot \left[-\cos\left(\frac{\pi}{2}\right) + \cos 0 \right] dy = \int_0^{\pi/3} \cos y \cdot (-0 + 1) dy \\ &= \int_0^{\pi/3} \cos y dy = [\sin y]_0^{\pi/3} = \sin\left(\frac{\pi}{3}\right) - \sin 0 = \frac{\sqrt{3}}{2} - 0 = \boxed{\frac{\sqrt{3}}{2}}. \end{aligned}$$

10. We begin by graphing $z = f(x, y) = e^x \cos y$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 1$, $0 \leq y \leq \frac{\pi}{2}$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R e^x \cos y dA$. Using Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^1 \int_0^{\pi/2} e^x \cos y dy dx = \int_0^1 e^x [\sin y]_0^{\pi/2} dx = \int_0^1 e^x \left[\sin\left(\frac{\pi}{2}\right) - \sin 0 \right] dx \\ &= \int_0^1 e^x (1 - 0) dx = \int_0^1 e^x dx = [e^x]_0^1 = e^1 - e^0 = \boxed{e - 1 \text{ cubic units}}. \end{aligned}$$

11. We begin by graphing $z = f(x, y) = 2x^2 + y^2$ and the rectangular region R as shown in the figure below. Since $z = f(x, y)$ is continuous and $z \geq 0$ over the rectangular region $0 \leq x \leq 2$, $0 \leq y \leq 1$, the volume V under the surface $z = f(x, y)$ is given by $V = \iint_R f(x, y) dA = \iint_R (2x^2 + y^2) dA$. Using Fubini's Theorem, we have

$$\begin{aligned} V &= \int_0^1 \int_0^2 (2x^2 + y^2) dx dy = \int_0^1 \left[\frac{2}{3}x^3 + xy^2 \right]_0^2 dy \\ &= \int_0^1 \left(\frac{16}{3} + 2y^2 \right) dy = \left[\frac{16}{3}y + \frac{2}{3}y^3 \right]_0^1 = \left(\frac{16}{3} + \frac{2}{3} \right) - 0 = \boxed{6 \text{ cubic units}}. \end{aligned}$$

12. (a) Using properties of double integrals,

$$\begin{aligned} \iint_R 2[f(x, y) + 3g(x, y)] dA &= \iint_R [2f(x, y) + 6g(x, y)] dA = \iint_R 2f(x, y) dA + \iint_R 6g(x, y) dA \\ &= 2 \iint_R f(x, y) dA + 6 \iint_R g(x, y) dA = 2 \cdot (-2) + 6 \cdot 3 = \boxed{14}. \end{aligned}$$

- (b) Using properties of double integrals,

$$\begin{aligned} \iint_R [g(x, y) - 2f(x, y)] dA &= \iint_R g(x, y) dA - \iint_R 2f(x, y) dA \\ &= \iint_R g(x, y) dA - 2 \iint_R f(x, y) dA = 3 - 2 \cdot (-2) = \boxed{7}. \end{aligned}$$

13. We begin by graphing the region R enclosed by the triangle with vertices $(0, 0)$, $(0, 2)$, and $(2, 2)$; see the figure below. Observe that R is a closed bounded region that is y -simple: it is bounded by the graphs of $x = 0$ and $x = y$, where $0 \leq y \leq 2$. So we can apply Fubini's Theorem for y -simple regions:

$$\begin{aligned} \iint_R x \sin(y^3) dA &= \int_0^2 \int_0^y x \sin(y^3) dx dy = \int_0^2 \sin(y^3) \cdot \left[\frac{x^2}{2} \right]_0^y dy \\ &= \int_0^2 \sin(y^3) \cdot \left(\frac{y^2}{2} - 0 \right) dy = \frac{1}{2} \int_0^2 \sin(y^3) \cdot y^2 dy. \end{aligned}$$

To complete evaluating this integral, we make a substitution $u = y^3$; then $du = 3y^2 dy$, so $y^2 dy = \frac{du}{3}$.

We also change the limits of integration: if $y = 0$, then $u = 0^3 = 0$; if $y = 2$, then $u = 2^3 = 8$. So

$$\begin{aligned} \frac{1}{2} \int_0^2 \sin(y^3) \cdot y^2 dy &= \frac{1}{2} \int_0^8 \sin u \cdot \left(\frac{du}{3}\right) = \frac{1}{6} \int_0^8 \sin u du \\ &= \frac{1}{6} [-\cos u]_0^8 = \frac{1}{6} (-\cos 8 + \cos 0) = \boxed{\frac{1 - \cos 8}{6}}. \end{aligned}$$

14. We begin by graphing the region R enclosed by $y = x$ and $y^2 = 2 - x$; see the figure below. Observe that R is a closed bounded region, that is y -simple: it is bounded by the graphs of $x = y$ and $x = 2 - y^2$, where $-2 \leq y \leq 1$. So we can apply Fubini's Theorem for y -simple regions:

$$\begin{aligned} \iint_R (x + y) dA &= \int_{-2}^1 \int_y^{2-y^2} (x + y) dx dy = \int_{-2}^1 \left[\frac{x^2}{2} + xy \right]_y^{2-y^2} dy \\ &= \int_{-2}^1 \left\{ \left[\frac{(2-y^2)^2}{2} + (2-y^2)y \right] - \left[\frac{y^2}{2} + y^2 \right] \right\} dy \\ &= \int_{-2}^1 \left(2 - 2y^2 + \frac{y^4}{2} + 2y - y^3 - \frac{3y^2}{2} \right) dy \\ &= \int_{-2}^1 \left(\frac{y^4}{2} - y^3 - \frac{7y^2}{2} + 2y + 2 \right) dy \\ &= \left[\frac{y^5}{10} - \frac{y^4}{4} - \frac{7y^3}{6} + y^2 + 2y \right]_{-2}^1 \\ &= \left(\frac{1}{10} - \frac{1}{4} - \frac{7}{6} + 1 + 2 \right) - \left(-\frac{16}{5} - 4 + \frac{28}{3} + 4 - 4 \right) = \boxed{-\frac{9}{20}}. \end{aligned}$$

15. We begin by graphing the solid S enclosed by the plane $2x + y + 3z = 6$ and the coordinate planes. This solid lies in the first octant under the graph of $z = f(x, y) = 2 - \frac{2x}{3} - \frac{y}{3}$ and above the region R

in the xy -plane bounded by the coordinate axes and the line $2x + y = 6$. Observe that R is an x -simple region: y varies from $y = 0$ to $y = 6 - 2x$, where $0 \leq x \leq 3$; see the figures below. So the volume V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) \, dA = \int_0^3 \int_0^{6-2x} \left(2 - \frac{2x}{3} - \frac{y}{3} \right) \, dy \, dx = \int_0^3 \left[2y - \frac{2xy}{3} - \frac{y^2}{6} \right]_0^{6-2x} \, dx \\
 &= \int_0^3 \left\{ \left[2(6-2x) - \frac{2x(6-2x)}{3} - \frac{(6-2x)^2}{6} \right] - 0 \right\} \, dx \\
 &= \int_0^3 \left[(12-4x) - \left(4x - \frac{4x^2}{3} \right) - \left(6-4x + \frac{2x^2}{3} \right) \right] \, dx \\
 &= \int_0^3 \left(\frac{2x^2}{3} - 4x + 6 \right) \, dx = \left[\frac{2x^3}{9} - 2x^2 + 6x \right]_0^3 = (6 - 18 + 18) - 0 = \boxed{6 \text{ cubic units}}.
 \end{aligned}$$

16. The ellipsoid $4x^2 + y^2 + \frac{z^2}{4} = 1$, shown in figure (a) below, is symmetric about all coordinate planes. So we can find its volume if we find the volume of its part lying in the first octant and multiply it by 8. The solid S that is the part of the ellipsoid $4x^2 + y^2 + \frac{z^2}{4} = 1$ lying in the first octant is shown in figure (b) below. It is enclosed by the surface $z = f(x, y) = \sqrt{4 - 16x^2 - 4y^2} = 2\sqrt{1 - 4x^2 - y^2}$ and the xy -plane (that is $z = 0$), and it lies above the region R in the xy -plane, that is the quarter of the ellipse $4x^2 + y^2 \leq 1$ in the first quadrant, shown in figure (c) below. So the volume V of the entire ellipsoid is 8 times the volume of the solid S :

$$V = 8 \iint_R f(x, y) \, dA = 8 \iint_R 2\sqrt{1 - 4x^2 - y^2} \, dA = 16 \iint_R \sqrt{1 - 4x^2 - y^2} \, dA.$$

To evaluate this integral, we can make the following change of variables:

$$x = \frac{1}{2}r \cos \theta, \quad y = r \sin \theta.$$

The partial derivatives are

$$\frac{\partial x}{\partial r} = \frac{1}{2} \cos \theta, \quad \frac{\partial x}{\partial \theta} = -\frac{1}{2}r \sin \theta, \quad \frac{\partial y}{\partial r} = \sin \theta, \quad \frac{\partial y}{\partial \theta} = r \cos \theta.$$

Then the Jacobian of x, y with respect to r, θ is

$$\begin{aligned}
 \frac{\partial(x, y)}{\partial(r, \theta)} &= \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{vmatrix} = \begin{vmatrix} \frac{1}{2} \cos \theta & -\frac{1}{2}r \sin \theta \\ \sin \theta & r \cos \theta \end{vmatrix} \\
 &= \frac{1}{2} \cos \theta \cdot r \cos \theta - \left(-\frac{1}{2}r \sin \theta \right) \cdot \sin \theta = \frac{1}{2}r \cos^2 \theta + \frac{1}{2}r \sin^2 \theta = \frac{1}{2}r.
 \end{aligned}$$

In the new coordinates r, θ , the equation of the boundary of the quarter-ellipse region R takes the form

$$4x^2 + y^2 = 4 \cdot \left(\frac{1}{2}r \cos \theta\right)^2 + (r \sin \theta)^2 = r^2 \cos^2 \theta + r^2 \sin^2 \theta = r^2 = 1, \quad \text{so} \quad r = 1.$$

The integrand can be rewritten (using the computation above) as

$$\sqrt{1 - 4x^2 - y^2} = \sqrt{1 - (4x^2 + y^2)} = \sqrt{1 - r^2}.$$

So in the new coordinates the integral for the volume is

$$V = 16 \iint_R \sqrt{1 - 4x^2 - y^2} dA = 16 \int_0^{\pi/2} \int_0^1 \sqrt{1 - r^2} \cdot \frac{1}{2} r dr d\theta = 8 \int_0^{\pi/2} \int_0^1 \sqrt{1 - r^2} \cdot r dr d\theta.$$

To evaluate the “inside” integral $\int_0^1 \sqrt{1 - r^2} \cdot r dr$, we make a substitution $u = 1 - r^2$; then $du = -2r dr$, so $r dr = \frac{du}{-2}$. We also change the limits of integration: if $r = 0$, then $u = 1 - 0^2 = 1$; if $r = 1$, then $u = 1 - 1^2 = 0$. So

$$\begin{aligned} \int_0^1 \sqrt{1 - r^2} \cdot r dr &= \int_1^0 \sqrt{u} \left(\frac{du}{-2}\right) = -\frac{1}{2} \int_1^0 \sqrt{u} du \\ &= \frac{1}{2} \int_0^1 u^{1/2} du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_0^1 = \frac{1}{3} \left[u^{3/2} \right]_0^1 = \frac{1}{3} (1 - 0) = \frac{1}{3}. \end{aligned}$$

Going back to the computation of the volume,

$$V = 8 \int_0^{\pi/2} \int_0^1 \sqrt{1 - r^2} \cdot r dr d\theta = 8 \int_0^{\pi/2} \frac{1}{3} d\theta = \frac{8}{3} [\theta]_0^{\pi/2} = \frac{8}{3} \left(\frac{\pi}{2} - 0\right) = \boxed{\frac{4\pi}{3} \text{ cubic units}}.$$

(a)

(b)

(c)

17. We begin by graphing the solid S enclosed in the first octant by the coordinate planes and the graphs of $4y = 3(4 - x^2)$ and $4z = 4 - x^2$. This solid lies under the surface $4z = 4 - x^2$, or equivalently $z = f(x, y) = 1 - \frac{x^2}{4}$, over the region R in the xy -plane bounded by the coordinate axes and the graph of $4y = 3(4 - x^2)$, or equivalently $y = 3 - \frac{3x^2}{4}$, in the first quadrant; see the figures below. Observe that R is an x -simple region: y varies from $y = 0$ to $y = 3 \left(1 - \frac{x^2}{4}\right)$, where $0 \leq x \leq 2$. So the volume

V of the solid S is

$$\begin{aligned}
 V &= \iint_R f(x, y) \, dA = \int_0^2 \int_0^{3(1-x^2/4)} \left(1 - \frac{x^2}{4}\right) dy \, dx = \int_0^2 \left(1 - \frac{x^2}{4}\right) [y]_0^{3(1-x^2/4)} dx \\
 &= \int_0^2 \left(1 - \frac{x^2}{4}\right) \cdot \left[3\left(1 - \frac{x^2}{4}\right) - 0\right] dx = 3 \int_0^2 \left(1 - \frac{x^2}{4}\right)^2 dx \\
 &= 3 \int_0^2 \left(1 - \frac{x^2}{2} + \frac{x^4}{16}\right) dx = 3 \left[x - \frac{x^3}{6} + \frac{x^5}{80}\right]_0^2 \\
 &= 3 \left[\left(2 - \frac{8}{6} + \frac{32}{80}\right) - 0\right] = 3 \cdot \frac{16}{15} = \boxed{\frac{16}{5} \text{ cubic units}}.
 \end{aligned}$$

18. We begin by graphing the region R enclosed by the parabola $y^2 = 16x$ and the line $y = 4x - 8$; see the figure below. Observe that R is a closed bounded region, that is y -simple: x varies from $x = \frac{y^2}{16}$ to $x = 2 + \frac{y}{4}$, where $-4 \leq y \leq 8$. Then the area A of the region R is

$$\begin{aligned}
 A &= \iint_R dA = \int_{-4}^8 \int_{y^2/16}^{2+y/4} dx \, dy = \int_{-4}^8 [x]_{y^2/16}^{2+y/4} dy = \int_{-4}^8 \left(2 + \frac{y}{4} - \frac{y^2}{16}\right) dy \\
 &= \left[2y + \frac{y^2}{8} - \frac{y^3}{48}\right]_{-4}^8 = \left[2 \cdot 8 + \frac{8^2}{8} - \frac{8^3}{48}\right] - \left[2 \cdot (-4) + \frac{(-4)^2}{8} - \frac{(-4)^3}{48}\right] \\
 &= \left(16 + 8 - \frac{32}{3}\right) - \left(-8 + 2 + \frac{4}{3}\right) = \boxed{18 \text{ square units}}.
 \end{aligned}$$

19. The region R enclosed by the rays $\theta = 0$ and $\theta = \frac{\pi}{6}$ and the circle $r = 6 \sin \theta$ is shown in the figure below. To find the given double integral, we rewrite it as an iterated integral and then evaluate.

$$\begin{aligned} \iint_R \sin \theta \, dA &= \int_0^{\pi/6} \int_0^{6 \sin \theta} \sin \theta \cdot r \, dr \, d\theta = \int_0^{\pi/6} \sin \theta \cdot \left[\frac{r^2}{2} \right]_0^{6 \sin \theta} d\theta \\ &= \int_0^{\pi/6} \sin \theta \cdot (18 \sin^2 \theta - 0) \, d\theta = 18 \int_0^{\pi/6} (1 - \cos^2 \theta) \sin \theta \, d\theta. \end{aligned}$$

To evaluate this integral, we make a substitution $u = \cos \theta$; then $du = -\sin \theta \, d\theta$, so $\sin \theta \, d\theta = -du$. We also change the limits of integration: if $\theta = 0$, then $u = \cos 0 = 1$; if $\theta = \frac{\pi}{6}$, then $u = \cos \frac{\pi}{6} = \frac{\sqrt{3}}{2}$. So

$$\begin{aligned} 18 \int_0^{\pi/6} (1 - \cos^2 \theta) \sin \theta \, d\theta &= 18 \int_1^{\sqrt{3}/2} (1 - u^2) (-du) = -18 \int_1^{\sqrt{3}/2} (1 - u^2) \, du \\ &= 18 \int_{\sqrt{3}/2}^1 (1 - u^2) \, du = 18 \left[u - \frac{u^3}{3} \right]_{\sqrt{3}/2}^1 = [18u - 6u^3]_{\sqrt{3}/2}^1 \\ &= [18 \cdot 1 - 6 \cdot 1^3] - \left[18 \cdot \frac{\sqrt{3}}{2} - 6 \cdot \left(\frac{\sqrt{3}}{2} \right)^3 \right] \\ &= 12 - \left(9\sqrt{3} - 6 \cdot \frac{3\sqrt{3}}{8} \right) = \boxed{12 - \frac{27\sqrt{3}}{4}}. \end{aligned}$$

20. We begin by graphing the region R enclosed in the first quadrant by the graphs $y^2 = x^3$ and $y = x$; see the figure below. Observe that R is a closed bounded region, that is x -simple: y varies from $y = x^{3/2}$ to $y = x$, where $0 \leq x \leq 1$. Then the area A of the region R is

$$\begin{aligned} A &= \iint_R dA = \int_0^1 \int_{x^{3/2}}^x dy \, dx = \int_0^1 [y]_{x^{3/2}}^x \, dx = \int_0^1 (x - x^{3/2}) \, dx \\ &= \left[\frac{x^2}{2} - \frac{x^{5/2}}{5/2} \right]_0^1 = \left[\frac{x^2}{2} - \frac{2x^{5/2}}{5} \right]_0^1 = \left(\frac{1}{2} - \frac{2}{5} \right) - 0 = \boxed{\frac{1}{10} \text{ square units}}. \end{aligned}$$

21. We begin by graphing the region R lying inside the circle $r = 2 \cos \theta$; see the figure. The region R can be defined in polar coordinates as $0 \leq r \leq 2 \cos \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then the area of R can be found as

$$\begin{aligned}
 A &= \iint_R dA = \int_{-\pi/2}^{\pi/2} \int_0^{2 \cos \theta} r \, dr \, d\theta = \int_{-\pi/2}^{\pi/2} \left[\frac{r^2}{2} \right]_0^{2 \cos \theta} d\theta = \int_{-\pi/2}^{\pi/2} \left[\frac{(2 \cos \theta)^2}{2} - 0 \right] d\theta \\
 &= \int_{-\pi/2}^{\pi/2} 2 \cos^2 \theta \, d\theta = \int_{-\pi/2}^{\pi/2} 2 \cdot \frac{1}{2} (1 + \cos 2\theta) \, d\theta = \left[\theta + \frac{\sin 2\theta}{2} \right]_{-\pi/2}^{\pi/2} \\
 &= \left[\left(\frac{\pi}{2} + \frac{\sin \pi}{2} \right) - \left(-\frac{\pi}{2} + \frac{\sin(-\pi)}{2} \right) \right] = \left[\left(\frac{\pi}{2} + 0 \right) - \left(-\frac{\pi}{2} + 0 \right) \right] = \boxed{\pi \text{ square units}}.
 \end{aligned}$$

22. We begin by graphing the region R lying in the first quadrant outside the circle $r = 2a$ but inside the circle $r = 4a \cos \theta$; see the figure below. In the first quadrant, the graphs intersect at the point where

$$4a \cos \theta = 2a, \quad \text{so} \quad \cos \theta = \frac{1}{2}, \quad \text{so} \quad \theta = \frac{\pi}{3}.$$

So the region R can be defined in polar coordinates as $2a \leq r \leq 4a \cos \theta$, $0 \leq \theta \leq \frac{\pi}{3}$. Then the area A of the region R can be found as

$$\begin{aligned}
 A &= \iint_R dA = \int_0^{\pi/3} \int_{2a}^{4a \cos \theta} r \, dr \, d\theta = \int_0^{\pi/3} \left[\frac{r^2}{2} \right]_{2a}^{4a \cos \theta} d\theta = \int_0^{\pi/3} (8a^2 \cos^2 \theta - 2a^2) \, d\theta \\
 &= 2a^2 \int_0^{\pi/3} (4 \cos^2 \theta - 1) \, d\theta = 2a^2 \int_0^{\pi/3} \left(4 \cdot \frac{1}{2} (1 + \cos 2\theta) - 1 \right) d\theta \\
 &= 2a^2 \int_0^{\pi/3} (1 + 2 \cos 2\theta) \, d\theta = 2a^2 [\theta + \sin 2\theta]_0^{\pi/3} = 2a^2 \left[\left(\frac{\pi}{3} + \sin \frac{2\pi}{3} \right) - (0 + 0) \right] \\
 &= 2a^2 \left(\frac{\pi}{3} + \frac{\sqrt{3}}{2} \right) = \boxed{a^2 \left(\frac{2\pi}{3} + \sqrt{3} \right) \text{ square units}}.
 \end{aligned}$$

23. Place the lamina on the cartesian coordinate plane so that its vertex at the right angle is at the origin and its base and height are on the positive directions of the x - and y -axes respectively; see the figure below. Then the region R occupied by the lamina can be described as bounded between $y = 0$ and $y = 6 - \frac{3x}{2}$, $0 \leq x \leq 4$. The mass density of the lamina is proportional to the square of the distance from the origin (where the vertex at the right angle has been placed); that is, $\rho(x, y) = k(x^2 + y^2)$, where k is a constant coefficient of proportionality. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R k(x^2 + y^2) dA = k \int_0^4 \int_0^{6-3x/2} (x^2 + y^2) dy dx \\
 &= k \int_0^4 \left[x^2 y + \frac{y^3}{3} \right]_0^{6-3x/2} dx = k \int_0^4 \left\{ x^2 \left(6 - \frac{3x}{2} \right) + \frac{\left(6 - \frac{3x}{2} \right)^3}{3} \right\} dx \\
 &= k \int_0^4 \left(6x^2 - \frac{3x^3}{2} + 72 - 54x + \frac{27x^2}{2} - \frac{9x^3}{8} \right) dx = k \int_0^4 \left(72 - 54x + \frac{39x^2}{2} - \frac{21x^3}{8} \right) dx \\
 &= k \left[72x - 27x^2 + \frac{13x^3}{2} - \frac{21x^4}{32} \right]_0^4 = k [(288 - 432 + 416 - 168) - 0] = \boxed{104k}.
 \end{aligned}$$

24. The region R enclosed by $3x^2 = y$ and $y = 3x$ is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 3x^2$ and $y = 3x$, $0 \leq x \leq 1$. The lamina is homogeneous; that is, its mass density is $\rho(x, y) = \rho$, a constant. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned}
 M &= \iint_R \rho(x, y) dA = \iint_R \rho dA = \rho \int_0^1 \int_{3x^2}^{3x} dy dx = \rho \int_0^1 [y]_{3x^2}^{3x} dx \\
 &= \rho \int_0^1 (3x - 3x^2) dx = \rho \left[\frac{3x^2}{2} - x^3 \right]_0^1 = \rho \left[\left(\frac{3}{2} - 1 \right) - 0 \right] = \frac{1}{2}\rho.
 \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x\rho dA = \rho \int_0^1 \int_{3x^2}^{3x} x dy dx = \rho \int_0^1 x[y]_{3x^2}^{3x} dx \\ &= \rho \int_0^1 x(3x - 3x^2) dx = \rho \int_0^1 (3x^2 - 3x^3) dx = \rho \left[x^3 - \frac{3x^4}{4} \right]_0^1 = \rho \left[\left(1 - \frac{3}{4}\right) - 0 \right] = \frac{1}{4}\rho, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{(1/4)\rho}{(1/2)\rho} = \frac{1}{2}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R y\rho dA = \rho \int_0^1 \int_{3x^2}^{3x} y dy dx = \rho \int_0^1 \left[\frac{y^2}{2} \right]_{3x^2}^{3x} dx \\ &= \rho \int_0^1 \left(\frac{9x^2}{2} - \frac{9x^4}{2} \right) dx = \frac{9}{2}\rho \int_0^1 (x^2 - x^4) dx \\ &= \frac{9}{2}\rho \left[\frac{x^3}{3} - \frac{x^5}{5} \right]_0^1 = \frac{9}{2}\rho \left[\left(\frac{1}{3} - \frac{1}{5} \right) - 0 \right] = \frac{9}{2}\rho \cdot \frac{2}{15} = \frac{3}{5}\rho, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{(3/5)\rho}{(1/2)\rho} = \frac{6}{5}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \boxed{\left(\frac{1}{2}, \frac{6}{5}\right)}$.

25. The region R enclosed in the first quadrant by $4x = y^2$, $y = 0$, and $x = 4$ is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = 0$ and $y = 2\sqrt{x}$, $0 \leq x \leq 4$. The lamina is homogeneous; that is, its mass density is $\rho(x, y) = \rho$, a constant. Then the mass M of the lamina can be found as a double integral:

$$\begin{aligned} M &= \iint_R \rho(x, y) dA = \iint_R \rho dA = \rho \int_0^4 \int_0^{2\sqrt{x}} dy dx = \rho \int_0^4 [y]_0^{2\sqrt{x}} dx \\ &= \rho \int_0^4 (2\sqrt{x} - 0) dx = 2\rho \int_0^4 x^{1/2} dx = 2\rho \left[\frac{x^{3/2}}{3/2} \right]_0^4 = \frac{4}{3}\rho \left[(\sqrt{x})^3 \right]_0^4 = \frac{4}{3}\rho(8 - 0) = \frac{32}{3}\rho. \end{aligned}$$

To find the center of mass of the lamina, we need to find the moments of mass about the x - and y -axes. The moment of mass about the y -axis is

$$\begin{aligned} M_y &= \iint_R x\rho(x, y) dA = \iint_R x\rho dA = \rho \int_0^4 \int_0^{2\sqrt{x}} x dy dx = \rho \int_0^4 x[y]_0^{2\sqrt{x}} dx \\ &= \rho \int_0^4 x(2\sqrt{x} - 0) dx = 2\rho \int_0^4 x^{3/2} dx = 2\rho \left[\frac{x^{5/2}}{5/2} \right]_0^4 = \frac{4}{5}\rho \left[(\sqrt{x})^5 \right]_0^4 = \frac{4}{5}\rho(32 - 0) = \frac{128}{5}\rho, \end{aligned}$$

$$\text{so } \bar{x} = \frac{M_y}{M} = \frac{(128/5)\rho}{(32/3)\rho} = \frac{12}{5}.$$

Similarly, the moment of mass about the x -axis is

$$\begin{aligned} M_x &= \iint_R y\rho(x, y) dA = \iint_R y\rho dA = \rho \int_0^4 \int_0^{2\sqrt{x}} y dy dx = \rho \int_0^4 \left[\frac{y^2}{2} \right]_0^{2\sqrt{x}} dx \\ &= \rho \int_0^4 (2x - 0) dx = \rho \int_0^4 2x dx = \rho [x^2]_0^4 = \rho(16 - 0) = 16\rho, \end{aligned}$$

$$\text{so } \bar{y} = \frac{M_x}{M} = \frac{16\rho}{(32/3)\rho} = \frac{3}{2}.$$

The center of mass of this lamina is at the point $(\bar{x}, \bar{y}) = \left(\frac{12}{5}, \frac{3}{2} \right)$.

26. The ellipse $2x^2 + 9y^2 = 18$ representing this lamina is shown in the figure below. Notice that R is an x -simple region: it is bounded between $y = -\sqrt{2\left(1 - \frac{x^2}{9}\right)}$ and $y = \sqrt{2\left(1 - \frac{x^2}{9}\right)}$, $-3 \leq x \leq 3$. Assuming that the lamina is homogeneous of constant mass density ρ , its moment of inertia about the x -axis can be found as a double integral:

$$\begin{aligned} I_x &= \iint_R y^2 \rho(x, y) dA = \iint_R y^2 \rho dA = \rho \int_{-3}^3 \int_{-\sqrt{2(1-x^2/9)}}^{\sqrt{2(1-x^2/9)}} y^2 dy dx = \rho \int_{-3}^3 \left[\frac{y^3}{3} \right]_{-\sqrt{2(1-x^2/9)}}^{\sqrt{2(1-x^2/9)}} dx \\ &= \rho \int_{-3}^3 \frac{1}{3} \left\{ \left[\sqrt{2\left(1 - \frac{x^2}{9}\right)} \right]^3 - \left[-\sqrt{2\left(1 - \frac{x^2}{9}\right)} \right]^3 \right\} dx = \rho \int_{-3}^3 \frac{1}{3} \cdot 2 \left[\sqrt{2\left(1 - \frac{x^2}{9}\right)} \right]^3 dx \\ &= \frac{2}{3}\rho \int_{-3}^3 2\sqrt{2} \left(\sqrt{1 - \frac{x^2}{9}} \right)^3 dx = \frac{4\sqrt{2}}{3}\rho \int_{-3}^3 \left(\sqrt{1 - \frac{x^2}{9}} \right)^3 dx. \end{aligned}$$

To evaluate this integral, we make a substitution $x = 3 \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dx = 3 \cos \theta d\theta$. We also change the limits of integration: if $x = -3$, then $-3 = 3 \sin \theta$, so $\sin \theta = -1$ and $\theta = -\frac{\pi}{2}$; if $x = 3$, then $3 = 3 \sin \theta$, so $\sin \theta = 1$ and $\theta = \frac{\pi}{2}$. The radical in the integrand simplifies as

$$\sqrt{1 - \frac{x^2}{9}} = \sqrt{1 - \frac{9 \sin^2 \theta}{9}} = \sqrt{1 - \sin^2 \theta} = \sqrt{\cos^2 \theta} = \cos \theta,$$

where we used the fact that $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ and so $\cos \theta \geq 0$. So the integral transforms into

$$\begin{aligned} I_x &= \frac{4\sqrt{2}}{3} \rho \int_{-3}^3 \left(\sqrt{1 - \frac{x^2}{9}} \right)^3 dx = \frac{4\sqrt{2}}{3} \rho \int_{-\pi/2}^{\pi/2} (\cos \theta)^3 \cdot 3 \cos \theta d\theta = 4\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} \cos^4 \theta d\theta \\ &= 4\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} (\cos^2 \theta)^2 d\theta = 4\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} \left[\frac{1}{2}(1 + \cos 2\theta) \right]^2 d\theta \\ &= 4\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} \frac{1}{4}(1 + 2 \cos 2\theta + \cos^2 2\theta) d\theta = \sqrt{2} \rho \int_{-\pi/2}^{\pi/2} \left[1 + 2 \cos 2\theta + \frac{1}{2}(1 + \cos 4\theta) \right] d\theta \\ &= \sqrt{2} \rho \int_{-\pi/2}^{\pi/2} \left(\frac{3}{2} + 2 \cos 2\theta + \frac{1}{2} \cos 4\theta \right) d\theta = \sqrt{2} \rho \left[\frac{3}{2} \theta + \sin 2\theta + \frac{1}{8} \sin 4\theta \right]_{-\pi/2}^{\pi/2} \\ &= \sqrt{2} \rho \left[\left(\frac{3}{2} \cdot \frac{\pi}{2} + \sin \pi + \frac{1}{8} \sin 2\pi \right) - \left(\frac{3}{2} \cdot \left(-\frac{\pi}{2} \right) + \sin(-\pi) + \frac{1}{8} \sin(-2\pi) \right) \right] \\ &= \sqrt{2} \rho \left[\left(\frac{3\pi}{4} + 0 + 0 \right) - \left(-\frac{3\pi}{4} + 0 + 0 \right) \right] = \sqrt{2} \rho \cdot \frac{3\pi}{2} = \boxed{\frac{3\sqrt{2}\pi\rho}{2}}. \end{aligned}$$

The moment of inertia of this lamina about the y -axis can be found as a double integral:

$$\begin{aligned} I_y &= \iint_R x^2 \rho(x, y) dA = \iint_R x^2 \rho dA = \rho \int_{-3}^3 \int_{-\sqrt{2(1-x^2/9)}}^{\sqrt{2(1-x^2/9)}} x^2 dy dx = \rho \int_{-3}^3 x^2 [y]_{-\sqrt{2(1-x^2/9)}}^{\sqrt{2(1-x^2/9)}} dx \\ &= \rho \int_{-3}^3 x^2 \left[\sqrt{2 \left(1 - \frac{x^2}{9} \right)} + \sqrt{2 \left(1 - \frac{x^2}{9} \right)} \right] dx = 2\sqrt{2} \rho \int_{-3}^3 x^2 \sqrt{1 - \frac{x^2}{9}} dx. \end{aligned}$$

Applying the same substitution $x = 3 \sin \theta$ as above (in the computation of I_x), we transform this integral into

$$\begin{aligned} I_y &= 2\sqrt{2} \rho \int_{-3}^3 x^2 \sqrt{1 - \frac{x^2}{9}} dx = 2\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} (3 \sin \theta)^2 \cos \theta \cdot 3 \cos \theta d\theta \\ &= 2\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} 27 \sin^2 \theta \cos^2 \theta d\theta = 54\sqrt{2} \rho \int_{-\pi/2}^{\pi/2} \frac{1}{4} \cdot 4 \sin^2 \theta \cos^2 \theta d\theta = \frac{27\sqrt{2}}{2} \rho \int_{-\pi/2}^{\pi/2} \sin^2 2\theta d\theta \\ &= \frac{27\sqrt{2}}{2} \rho \int_{-\pi/2}^{\pi/2} \frac{1}{2}(1 - \cos 4\theta) d\theta = \frac{27\sqrt{2}}{4} \rho \int_{-\pi/2}^{\pi/2} (1 - \cos 4\theta) d\theta = \frac{27\sqrt{2}}{4} \rho \left[\theta - \frac{1}{4} \sin 4\theta \right]_{-\pi/2}^{\pi/2} \\ &= \frac{27\sqrt{2}}{4} \rho \left[\left(\frac{\pi}{2} - \frac{1}{4} \sin 2\pi \right) - \left(\left(-\frac{\pi}{2} \right) - \frac{1}{4} \sin(-2\pi) \right) \right] \\ &= \frac{27\sqrt{2}}{4} \rho \left[\left(\frac{\pi}{2} - 0 \right) - \left(-\frac{\pi}{2} - 0 \right) \right] = \frac{27\sqrt{2}}{4} \rho \cdot \pi = \boxed{\frac{27\sqrt{2}\pi\rho}{4}}. \end{aligned}$$

Finally, the moment of inertia of this lamina about the origin is

$$I_O = I_x + I_y = \frac{3\sqrt{2}\pi\rho}{2} + \frac{27\sqrt{2}\pi\rho}{4} = \boxed{\frac{33\sqrt{2}\pi\rho}{4}}.$$

27. The equation of the plane $\frac{x}{2} + y + \frac{z}{3} = 1$ can be rewritten as $z = f(x, y) = 3 - \frac{3x}{2} - 3y$. The first-octant portion of this plane is shown in figure (a) below. It lies over the triangular region R in the xy -plane bounded by the line $\frac{x}{2} + y = 1$, or equivalently $y = 1 - \frac{x}{2}$, and the coordinate axes in the first quadrant; see figure (b) below. In the xy -plane, R is given by $0 \leq y \leq 1 - \frac{x}{2}$, $0 \leq x \leq 2$.

The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = -\frac{3}{2}$ and $f_y(x, y) = -3$. Since both f_x and f_y are continuous on R , the surface area S of the part of the plane that lies in the first octant, that is above the region R , is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA = \iint_R \sqrt{\left(-\frac{3}{2}\right)^2 + (-3)^2 + 1} dA = \iint_R \sqrt{\frac{49}{4}} dA \\ &= \frac{7}{2} \iint_R dA = \frac{7}{2} \int_0^2 \int_0^{1-x/2} dy dx = \frac{7}{2} \int_0^2 [y]_0^{1-x/2} dx = \frac{7}{2} \int_0^2 \left[\left(1 - \frac{x}{2}\right) - 0 \right] dx \\ &= \frac{7}{2} \int_0^2 \left(1 - \frac{x}{2}\right) dx = \frac{7}{2} \left[x - \frac{x^2}{4} \right]_0^2 = \frac{7}{2} [(2 - 1) - 0] = \boxed{\frac{7}{2} \text{ square units}}. \end{aligned}$$

(a)

(b)

28. The part of the paraboloid $z = x^2 + y^2$ that lies below the plane $z = 1$ is shown in figure (a) below. If we substitute $z = 1$ into the equation of the paraboloid, we obtain $x^2 + y^2 = 1$. So the projection of this part of the paraboloid onto the xy -plane is the circular region R shown in figure (b) below; in polar coordinates R is given by $0 \leq r \leq 1$, $0 \leq \theta \leq 2\pi$.

The partial derivatives of $z = f(x, y) = x^2 + y^2$ are $f_x(x, y) = 2x$ and $f_y(x, y) = 2y$. Since both f_x and

f_y are continuous on R , the surface area S we seek is

$$\begin{aligned} S &= \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dA = \iint_R \sqrt{(2x)^2 + (2y)^2 + 1} \, dA \\ &= \iint_R \sqrt{4x^2 + 4y^2 + 1} \, dA = \iint_R \sqrt{4(x^2 + y^2) + 1} \, dA = \int_0^{2\pi} \int_0^1 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta. \end{aligned}$$

To evaluate the “inside” integral $\int_0^1 \sqrt{4r^2 + 1} \cdot r \, dr$, we make a substitution $u = 4r^2 + 1$; then $du = 8r \, dr$, so $r \, dr = \frac{1}{8} du$. We also change the limits of integration: if $r = 0$, then $u = 4 \cdot 0^2 + 1 = 1$; if $r = 1$, then $u = 4 \cdot 1^2 + 1 = 5$. So

$$\int_0^1 \sqrt{4r^2 + 1} \cdot r \, dr = \int_1^5 \sqrt{u} \cdot \frac{1}{8} \, du = \frac{1}{8} \int_1^5 u^{1/2} \, du = \frac{1}{8} \left[\frac{u^{3/2}}{3/2} \right]_1^5 = \frac{1}{12} \left[(\sqrt{u})^3 \right]_1^5 = \frac{5\sqrt{5} - 1}{12}.$$

Going back to the calculation of S ,

$$\begin{aligned} S &= \int_0^{2\pi} \int_0^1 \sqrt{4r^2 + 1} \cdot r \, dr \, d\theta = \int_0^{2\pi} \frac{5\sqrt{5} - 1}{12} \, d\theta \\ &= \frac{5\sqrt{5} - 1}{12} \cdot [\theta]_0^{2\pi} = \frac{5\sqrt{5} - 1}{12} \cdot (2\pi - 0) = \boxed{\frac{(5\sqrt{5} - 1)\pi}{6} \text{ square units}}. \end{aligned}$$

29. The part of the cone $x^2 + y^2 = 3z^2$ that lies inside the cylinder $x^2 + y^2 = 4y$ is shown in figure (a) below. Notice that it is symmetric about the xy -plane, so to find its surface area we can find the surface area of the part lying above the xy -plane and multiply it by 2. The upper nappe of this cone can be thought of as the graph of the function $z = f(x, y) = \frac{1}{\sqrt{3}} \sqrt{x^2 + y^2}$. It lies over the region R in the xy -plane that is the trace of the cylinder in this plane: R is defined by $x^2 + y^2 \leq 4y$ in Cartesian coordinates, and it is a disk of radius 2 centered at the point $(0, 2)$; see figure (b) below.

The partial derivatives of $z = f(x, y)$ are $f_x(x, y) = \frac{x}{\sqrt{3}\sqrt{x^2 + y^2}}$ and $f_y(x, y) = \frac{y}{\sqrt{3}\sqrt{x^2 + y^2}}$. Then

the surface area S we seek is

$$\begin{aligned}
 S &= 2 \iint_R \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} dA \\
 &= 2 \iint_R \sqrt{\left(\frac{x}{\sqrt{3}\sqrt{x^2 + y^2}}\right)^2 + \left(\frac{y}{\sqrt{3}\sqrt{x^2 + y^2}}\right)^2 + 1} dA \\
 &= 2 \iint_R \sqrt{\frac{x^2}{3(x^2 + y^2)} + \frac{y^2}{3(x^2 + y^2)} + 1} dA = 2 \iint_R \sqrt{\frac{x^2 + y^2}{3(x^2 + y^2)} + 1} dA \\
 &= 2 \iint_R \sqrt{\frac{1}{3} + 1} dA = 2 \iint_R \sqrt{\frac{4}{3}} dA = \frac{4}{\sqrt{3}} \iint_R dA \\
 &= \frac{4\sqrt{3}}{3} \cdot (\text{Area of the disk } R) = \frac{4\sqrt{3}}{3} \cdot (\pi \cdot 2^2) = \boxed{\frac{16\sqrt{3}\pi}{3} \text{ square units}}.
 \end{aligned}$$

(a)

(b)

30. Since the function $f(x, y, z) = e^z \cos x$ is continuous on the solid E defined by $0 \leq x \leq \frac{\pi}{2}$, $0 \leq y \leq 2$, $0 \leq z \leq 1$, we can use Fubini's Theorem for triple integrals:

$$\begin{aligned}
 \iiint_E e^z \cos x dV &= \int_0^{\pi/2} \int_0^2 \int_0^1 e^z \cos x dz dy dx = \int_0^{\pi/2} \int_0^2 \cos x \cdot [e^z]_0^1 dy dx \\
 &= \int_0^{\pi/2} \int_0^2 \cos x \cdot (e^1 - e^0) dy dx = (e - 1) \int_0^{\pi/2} \int_0^2 \cos x dy dx \\
 &= (e - 1) \int_0^{\pi/2} \cos x \cdot [y]_0^2 dx = (e - 1) \int_0^{\pi/2} \cos x \cdot (2 - 0) dx \\
 &= 2(e - 1) \int_0^{\pi/2} \cos x dx = 2(e - 1) \cdot [\sin x]_0^{\pi/2} \\
 &= 2(e - 1) \cdot \left(\sin \frac{\pi}{2} - \sin 0\right) = 2(e - 1) \cdot (1 - 0) = \boxed{2(e - 1)}.
 \end{aligned}$$

31. We evaluate the given iterated integral as follows:

$$\begin{aligned}
 \int_0^1 \int_0^{2-3x} \int_0^{2y} x^2 dz dy dx &= \int_0^1 \int_0^{2-3x} x^2 [z]_0^{2y} dy dx = \int_0^1 \int_0^{2-3x} x^2 (2y - 0) dy dx \\
 &= \int_0^1 \int_0^{2-3x} x^2 \cdot 2y dy dx = \int_0^1 x^2 [y^2]_0^{2-3x} dx \\
 &= \int_0^1 x^2 [(2-3x)^2 - 0] dx = \int_0^1 x^2 (4 - 12x + 9x^2) dx \\
 &= \int_0^1 (4x^2 - 12x^3 + 9x^4) dx = \left[\frac{4x^3}{3} - 3x^4 + \frac{9x^5}{5} \right]_0^1 \\
 &= \left(\frac{4}{3} - 3 + \frac{9}{5} \right) - 0 = \boxed{\frac{2}{15}}.
 \end{aligned}$$

32. Since the function $f(x, y, z) = ye^x$ is continuous on the solid E defined by $0 \leq x \leq 1$, $0 \leq y \leq 1$, $y^2 \leq z \leq y$, we can use Fubini's Theorem for triple integrals:

$$\begin{aligned}
 \iiint_E ye^x dV &= \int_0^1 \int_0^1 \int_{y^2}^y ye^x dz dy dx = \int_0^1 \int_0^1 ye^x \cdot [z]_{y^2}^y dy dx = \int_0^1 \int_0^1 ye^x \cdot (y - y^2) dy dx \\
 &= \int_0^1 \int_0^1 e^x (y^2 - y^3) dy dx = \int_0^1 e^x \left[\frac{y^3}{3} - \frac{y^4}{4} \right]_0^1 dx = \int_0^1 e^x \left[\left(\frac{1}{3} - \frac{1}{4} \right) - 0 \right] dx \\
 &= \frac{1}{12} \int_0^1 e^x dx = \frac{1}{12} [e^x]_0^1 = \frac{1}{12} (e^1 - e^0) = \boxed{\frac{e-1}{12}}.
 \end{aligned}$$

33. We begin by graphing the solid E enclosed by $x = 0$ and $x = 2 - y - z$ whose projection onto the yz -plane is the region enclosed by the rectangle $0 \leq y \leq 1$, $0 \leq z \leq 1$; see the figure below. Since the function $f(x, y, z) = xyz$ is continuous on E , we can use Fubini's Theorem for triple integrals:

$$\begin{aligned}
 \iiint_E xyz dV &= \int_0^1 \int_0^1 \int_0^{2-y-z} xyz dx dy dz = \int_0^1 \int_0^1 yz \cdot \left[\frac{x^2}{2} \right]_0^{2-y-z} dy dz \\
 &= \frac{1}{2} \int_0^1 \int_0^1 yz \cdot [(2-y-z)^2 - 0] dy dz \\
 &= \frac{1}{2} \int_0^1 \int_0^1 yz (4 + y^2 + z^2 - 4y - 4z + 2yz) dy dz \\
 &= \frac{1}{2} \int_0^1 \int_0^1 (4yz + y^3z + yz^3 - 4y^2z - 4yz^2 + 2y^2z^2) dy dz \\
 &= \frac{1}{2} \int_0^1 \left[2y^2z + \frac{1}{4}y^4z + \frac{1}{2}y^2z^3 - \frac{4}{3}y^3z - 2y^2z^2 + \frac{2}{3}y^3z^2 \right]_0^1 dz \\
 &= \frac{1}{2} \int_0^1 \left[\left(2z + \frac{1}{4}z + \frac{1}{2}z^3 - \frac{4}{3}z - 2z^2 + \frac{2}{3}z^2 \right) - 0 \right] dz \\
 &= \frac{1}{2} \int_0^1 \left(\frac{11}{12}z - \frac{4}{3}z^2 + \frac{1}{2}z^3 \right) dz = \frac{1}{2} \left[\frac{11}{24}z^2 - \frac{4}{9}z^3 + \frac{1}{8}z^4 \right]_0^1 \\
 &= \frac{1}{2} \left[\left(\frac{11}{24} - \frac{4}{9} + \frac{1}{8} \right) - 0 \right] = \frac{1}{2} \cdot \frac{5}{36} = \boxed{\frac{5}{72}}.
 \end{aligned}$$

34. First, we need to find the mass of the given solid E . In spherical coordinates, this hemispherical shell is described by $a \leq r \leq b$, $0 \leq \phi \leq \frac{\pi}{2}$, $0 \leq \theta \leq 2\pi$. Since it is homogeneous, its mass density is $\rho(x, y, z) = \delta$, a constant. Then the mass M of the solid E is

$$\begin{aligned}
 M &= \iiint_E \rho(x, y, z) dV = \int_0^{2\pi} \int_0^{\pi/2} \int_a^b \delta \cdot \rho^2 \sin \phi d\rho d\phi d\theta = \delta \int_0^{2\pi} \int_0^{\pi/2} \int_a^b \rho^2 \sin \phi d\rho d\phi d\theta \\
 &= \delta \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cdot \left[\frac{\rho^3}{3} \right]_a^b d\phi d\theta = \delta \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cdot \left(\frac{b^3}{3} - \frac{a^3}{3} \right) d\phi d\theta \\
 &= \frac{\delta(b^3 - a^3)}{3} \int_0^{2\pi} \int_0^{\pi/2} \sin \phi d\phi d\theta = \frac{\delta(b^3 - a^3)}{3} \int_0^{2\pi} [-\cos \phi]_0^{\pi/2} d\theta \\
 &= \frac{\delta(b^3 - a^3)}{3} \int_0^{2\pi} \left(-\cos \frac{\pi}{2} + \cos 0 \right) d\theta = \frac{\delta(b^3 - a^3)}{3} \int_0^{2\pi} (-0 + 1) d\theta = \frac{\delta(b^3 - a^3)}{3} \int_0^{2\pi} d\theta \\
 &= \frac{\delta(b^3 - a^3)}{3} [\theta]_0^{2\pi} = \frac{\delta(b^3 - a^3)}{3} (2\pi - 0) = \frac{2\pi\delta(b^3 - a^3)}{3}.
 \end{aligned}$$

The homogeneous solid E is symmetric about both yz - and xz -planes, so $\bar{x} = \bar{y} = 0$. The moment about the xy -plane is

$$\begin{aligned}
 M_{xy} &= \iiint_E z\rho(x, y, z) dV = \int_0^{2\pi} \int_0^{\pi/2} \int_a^b \rho \cos \phi \cdot \delta \cdot \rho^2 \sin \phi d\rho d\phi d\theta \\
 &= \delta \int_0^{2\pi} \int_0^{\pi/2} \int_a^b \rho^3 \sin \phi \cos \phi d\rho d\phi d\theta = \delta \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cos \phi \cdot \left[\frac{\rho^4}{4} \right]_a^b d\phi d\theta \\
 &= \delta \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cos \phi \cdot \left(\frac{b^4}{4} - \frac{a^4}{4} \right) d\phi d\theta = \frac{\delta(b^4 - a^4)}{4} \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cos \phi d\phi d\theta \\
 &= \frac{\delta(b^4 - a^4)}{4} \int_0^{2\pi} \int_0^{\pi/2} \frac{1}{2} \sin 2\phi d\phi d\theta = \frac{\delta(b^4 - a^4)}{4} \int_0^{2\pi} \frac{1}{4} [-\cos 2\phi]_0^{\pi/2} d\theta \\
 &= \frac{\delta(b^4 - a^4)}{16} \int_0^{2\pi} (-\cos \pi + \cos 0) d\theta = \frac{\delta(b^4 - a^4)}{16} \int_0^{2\pi} (1 + 1) d\theta = \frac{\delta(b^4 - a^4)}{8} \int_0^{2\pi} d\theta \\
 &= \frac{\delta(b^4 - a^4)}{8} [\theta]_0^{2\pi} = \frac{\delta(b^4 - a^4)}{8} (2\pi - 0) = \frac{\pi\delta(b^4 - a^4)}{4},
 \end{aligned}$$

so $\bar{z} = \frac{M_{xy}}{M} = \frac{\pi\delta(b^4 - a^4)/4}{2\pi\delta(b^3 - a^3)/3} = \frac{3(b^4 - a^4)}{8(b^3 - a^3)}$, and the center of mass is $\boxed{(\bar{x}, \bar{y}, \bar{z}) = \left(0, 0, \frac{3(b^4 - a^4)}{8(b^3 - a^3)} \right)}$.

Due to the symmetry of the hemispherical shell E , its moments of inertia about the x - and y -axes are the same. Using the fact that the distance from a point (x, y, z) to the x -axis is $r = \sqrt{y^2 + z^2}$, and so $r^2 = y^2 + z^2 = (\rho \sin \phi \cos \theta)^2 + (\rho \cos \phi)^2 = \rho^2(\sin^2 \phi \cos^2 \theta + \cos^2 \phi)$, we find that the moment of

inertia about the x -axis is

$$\begin{aligned}
 I_x &= \iiint_E r^2 \rho(x, y, z) dV = \int_0^{2\pi} \int_0^{\pi/2} \int_a^b \rho^2 (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \cdot \delta \cdot \rho^2 \sin \phi d\rho d\phi d\theta \\
 &= \delta \int_0^{2\pi} \int_0^{\pi/2} \int_a^b \rho^4 (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi d\rho d\phi d\theta \\
 &= \delta \int_0^{2\pi} \int_0^{\pi/2} (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi \cdot \left[\frac{\rho^5}{5} \right]_a^b d\phi d\theta \\
 &= \delta \int_0^{2\pi} \int_0^{\pi/2} (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi \cdot \left(\frac{b^5}{5} - \frac{a^5}{5} \right) d\phi d\theta \\
 &= \frac{\delta(b^5 - a^5)}{5} \int_0^{2\pi} \int_0^{\pi/2} (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi d\phi d\theta.
 \end{aligned}$$

Now, to evaluate the “inside” integral $\int_0^{\pi/2} (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi d\phi$, which must be integrated partially with respect to ϕ , we make a substitution $u = \cos \phi$; then $du = -\sin \phi d\phi$, so $\sin \phi d\phi = -du$. Using a trigonometric identity, in the integrand we can rewrite $\sin^2 \phi = 1 - \cos^2 \phi = 1 - u^2$. We also change the limits of integration: if $\phi = 0$, then $u = \cos 0 = 1$; if $\phi = \frac{\pi}{2}$, then $u = \cos \frac{\pi}{2} = 0$. So

$$\begin{aligned}
 \int_0^{\pi/2} (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi d\phi &= \int_1^0 [(1 - u^2) \cos^2 \theta + u^2] (-du) \\
 &= - \int_1^0 [\cos^2 \theta + u^2(1 - \cos^2 \theta)] du \\
 &= \int_0^1 (\cos^2 \theta + u^2 \sin^2 \theta) du = \left[u \cos^2 \theta + \frac{u^3}{3} \sin^2 \theta \right]_0^1 \\
 &= \left(\cos^2 \theta + \frac{1}{3} \sin^2 \theta \right) - (0 + 0) = \cos^2 \theta + \frac{1}{3} \sin^2 \theta.
 \end{aligned}$$

Going back to the computation of I_x ,

$$\begin{aligned}
 I_x &= \frac{\delta(b^5 - a^5)}{5} \int_0^{2\pi} \int_0^{\pi/2} (\sin^2 \phi \cos^2 \theta + \cos^2 \phi) \sin \phi d\phi d\theta \\
 &= \frac{\delta(b^5 - a^5)}{5} \int_0^{2\pi} \left(\cos^2 \theta + \frac{1}{3} \sin^2 \theta \right) d\theta \\
 &= \frac{\delta(b^5 - a^5)}{5} \int_0^{2\pi} \left[\frac{1}{2}(1 + \cos 2\theta) + \frac{1}{3} \cdot \frac{1}{2}(1 - \cos 2\theta) \right] d\theta \\
 &= \frac{\delta(b^5 - a^5)}{5} \int_0^{2\pi} \left(\frac{2}{3} + \frac{1}{3} \cos 2\theta \right) d\theta = \frac{\delta(b^5 - a^5)}{5} \left[\frac{2}{3}\theta + \frac{1}{6} \sin 2\theta \right]_0^{2\pi} \\
 &= \frac{\delta(b^5 - a^5)}{5} \left[\left(\frac{2}{3} \cdot 2\pi + \frac{1}{6} \sin 4\pi \right) - \left(\frac{2}{3} \cdot 0 + \frac{1}{6} \sin 0 \right) \right] = \frac{\delta(b^5 - a^5)}{5} \cdot \frac{4\pi}{3} = \frac{4\pi\delta(b^5 - a^5)}{15}.
 \end{aligned}$$

$$\text{So } I_x = I_y = \boxed{\frac{4\pi\delta(b^5 - a^5)}{15}}.$$

35. The part of the paraboloid $x^2 + y^2 + z = 9$ lying over the first quadrant and its projection onto the xy -plane are shown in the figures below. Since the equation of the paraboloid involves $x^2 + y^2$, it is convenient to switch to cylindrical coordinates: the given solid is bounded between $z = 0$ and

$z = 9 - (x^2 + y^2) = 9 - r^2$, where $0 \leq r \leq 3$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the volume is

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^{\pi/2} \int_0^3 \int_0^{9-r^2} r \, dz \, dr \, d\theta = \int_0^{\pi/2} \int_0^3 r[z]_0^{9-r^2} \, dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^3 r[(9-r^2) - 0] \, dr \, d\theta = \int_0^{\pi/2} \int_0^3 (9r - r^3) \, dr \, d\theta = \int_0^{\pi/2} \left[\frac{9r^2}{2} - \frac{r^4}{4} \right]_0^3 d\theta \\
 &= \int_0^{\pi/2} \left[\left(\frac{81}{2} - \frac{81}{4} \right) - (0 - 0) \right] d\theta = \int_0^{\pi/2} \frac{81}{4} d\theta = \frac{81}{4} [\theta]_0^{\pi/2} = \frac{81}{4} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{81\pi}{8} \text{ cubic units}}.
 \end{aligned}$$

36. The solid E enclosed in the first quadrant by $y = 0$, $z = 0$, $x + y = 2$, $x + 2y = 6$, and $y^2 + z^2 = 4$ is shown in figure (a) below; it is bounded between $z = 0$ and $z = \sqrt{4 - y^2}$. Its projection onto the xy -plane is the region R shown in figure (b) below; in the xy -plane it is bounded by the lines $x = 2 - y$ and $x = 6 - 2y$, where $0 \leq y \leq 2$. Then the volume V of the solid E is

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^2 \int_{2-y}^{6-2y} \int_0^{\sqrt{4-y^2}} dz \, dx \, dy = \int_0^2 \int_{2-y}^{6-2y} [z]_0^{\sqrt{4-y^2}} dx \, dy \\
 &= \int_0^2 \int_{2-y}^{6-2y} (\sqrt{4-y^2} - 0) dx \, dy = \int_0^2 \int_{2-y}^{6-2y} \sqrt{4-y^2} dx \, dy = \int_0^2 \sqrt{4-y^2} [x]_{2-y}^{6-2y} dy \\
 &= \int_0^2 \sqrt{4-y^2} [(6-2y) - (2-y)] dy = \int_0^2 \sqrt{4-y^2} (4-y) dy \\
 &= 4 \int_0^2 \sqrt{4-y^2} dy - \int_0^2 \sqrt{4-y^2} y dy.
 \end{aligned}$$

To evaluate the first integral, we make a substitution $y = 2 \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$; then $dy = 2 \cos \theta d\theta$. Using a trigonometric identity, we can rewrite the integrand as $\sqrt{4-y^2} = \sqrt{4-4\sin^2 \theta} = \sqrt{4(1-\sin^2 \theta)} = \sqrt{4\cos^2 \theta} = 2 \cos \theta$, where we used the fact that $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ and so $\cos \theta \geq 0$. We also change the limits of integration: if $y = 0$, then $2 \sin \theta = 0$ or $\sin \theta = 0$ and so $\theta = 0$; if $y = 2$, then $2 \sin \theta = 2$ or $\sin \theta = 1$ and so $\theta = \frac{\pi}{2}$. So the first integral becomes

$$\begin{aligned}
 4 \int_0^2 \sqrt{4-y^2} dy &= 4 \int_0^{\pi/2} 2 \cos \theta \cdot 2 \cos \theta d\theta = 16 \int_0^{\pi/2} \cos^2 \theta d\theta \\
 &= 16 \int_0^{\pi/2} \frac{1}{2} (1 + \cos 2\theta) d\theta = 8 \int_0^{\pi/2} (1 + \cos 2\theta) d\theta \\
 &= 8 \left[\theta + \frac{\sin 2\theta}{2} \right]_0^{\pi/2} = 8 \left[\left(\frac{\pi}{2} + \frac{\sin \pi}{2} \right) - \left(0 + \frac{\sin 0}{2} \right) \right] = 8 \cdot \frac{\pi}{2} = 4\pi.
 \end{aligned}$$

To evaluate the second integral, we make a substitution $u = 4 - y^2$; then $du = -2y dy$, so $y dy = \frac{du}{-2}$. We also change the limits of integration: if $y = 0$, then $u = 4 - 0^2 = 4$; if $y = 2$, then $u = 4 - 2^2 = 0$. So the second integral becomes

$$\begin{aligned} \int_0^2 \sqrt{4-y^2} y dy &= \int_4^0 \sqrt{u} \left(\frac{du}{-2} \right) = -\frac{1}{2} \int_4^0 \sqrt{u} du = \frac{1}{2} \int_0^4 u^{1/2} du \\ &= \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_0^4 = \frac{1}{3} \left[(\sqrt{u})^3 \right]_0^4 = \frac{1}{3} \left[(\sqrt{4})^3 - (\sqrt{0})^3 \right] = \frac{1}{3}(8-0) = \frac{8}{3}. \end{aligned}$$

So the final answer is

$$V = 4 \int_0^2 \sqrt{4-y^2} dy - \int_0^2 \sqrt{4-y^2} y dy = \boxed{4\pi - \frac{8}{3} \text{ cubic units}}.$$

(a)

(b)

37. (a) Since the z -coordinate in rectangular coordinates is 4, it is the z -coordinate in cylindrical coordinates as well. The value of r is $r = \sqrt{x^2 + y^2} = \sqrt{3^2 + 0^2} = \sqrt{9} = 3$. In the xy -plane, the point $(3, 0, 0)$ lies on the positive half of the x -axis, so $\theta = 0$. So the cylindrical coordinates of the cartesian point $(3, 0, 4)$ are $(r, \theta, z) = \boxed{(3, 0, 4)}$.
- (b) Since θ in cylindrical coordinates is 0, that is the value of θ in spherical coordinates as well. The value of ρ is $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{3^2 + 0^2 + 4^2} = \sqrt{25} = 5$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{4}{5}$, so $\phi = \cos^{-1} \left(\frac{4}{5} \right)$. So the spherical coordinates of the cartesian point $(3, 0, 4)$ are $(\rho, \theta, \phi) = \boxed{\left(5, 0, \cos^{-1} \left(\frac{4}{5} \right) \right)}$.
38. (a) Since the z -coordinate in rectangular coordinates is 3, it is the z -coordinate in cylindrical coordinates as well. The value of r is $r = \sqrt{x^2 + y^2} = \sqrt{(-2\sqrt{2})^2 + (2\sqrt{2})^2} = \sqrt{16} = 4$. In the xy -plane, the point $(-2\sqrt{2}, 2\sqrt{2}, 0)$ lies in the second quadrant; and since $\tan \theta = \frac{y}{x} = \frac{2\sqrt{2}}{-2\sqrt{2}} = -1$, then $\theta = \frac{3\pi}{4}$. So the cylindrical coordinates of the cartesian point $(-2\sqrt{2}, 2\sqrt{2}, 3)$ are $(r, \theta, z) = \boxed{\left(4, \frac{3\pi}{4}, 3 \right)}$.
- (b) Since θ in cylindrical coordinates is $\frac{3\pi}{4}$, that is the value of θ in spherical coordinates as well. The value of ρ is $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{(-2\sqrt{2})^2 + (2\sqrt{2})^2 + 3^2} = \sqrt{25} = 5$. Finally, $\cos \phi =$

$\frac{z}{\rho} = \frac{3}{5}$, so $\phi = \cos^{-1}\left(\frac{3}{5}\right)$. So the spherical coordinates of the cartesian point $(-2\sqrt{2}, 2\sqrt{2}, 3)$ are $(\rho, \theta, \phi) = \left(5, \frac{3\pi}{4}, \cos^{-1}\left(\frac{3}{5}\right)\right)$.

39. (a) Since the z -coordinate in rectangular coordinates is -2 , it is the z -coordinate in cylindrical coordinates as well. The value of r is $r = \sqrt{x^2 + y^2} = \sqrt{(-1)^2 + 1^2} = \sqrt{2}$. In the xy -plane, the point $(-1, 1, 0)$ lies in the second quadrant; and since $\tan \theta = \frac{y}{x} = \frac{1}{-1} = -1$, then $\theta = \frac{3\pi}{4}$. So the cylindrical coordinates of the cartesian point $(-1, 1, -2)$ are $(r, \theta, z) = \left(\sqrt{2}, \frac{3\pi}{4}, -2\right)$.

- (b) Since θ in cylindrical coordinates is $\frac{3\pi}{4}$, that is the value of θ in spherical coordinates as well. The value of ρ is $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{(-1)^2 + 1^2 + (-2)^2} = \sqrt{6}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{-2}{\sqrt{6}}$, so $\phi = \cos^{-1}\left(-\frac{2}{\sqrt{6}}\right)$. So the spherical coordinates of the cartesian point $(-1, 1, -2)$ are $(\rho, \theta, \phi) = \left(\sqrt{6}, \frac{3\pi}{4}, \cos^{-1}\left(-\frac{2}{\sqrt{6}}\right)\right)$.

40. (a) Since the z -coordinate in rectangular coordinates is 4 , it is the z -coordinate in cylindrical coordinates as well. The value of r is $r = \sqrt{x^2 + y^2} = \sqrt{1^2 + (\sqrt{3})^2} = \sqrt{4} = 2$. In the xy -plane, the point $(1, \sqrt{3}, 0)$ lies in the first quadrant; and since $\tan \theta = \frac{y}{x} = \frac{\sqrt{3}}{1} = \sqrt{3}$, then $\theta = \frac{\pi}{3}$. So the cylindrical coordinates of the cartesian point $(1, \sqrt{3}, 4)$ are $(r, \theta, z) = \left(2, \frac{\pi}{3}, 4\right)$.

- (b) Since θ in cylindrical coordinates is $\frac{\pi}{3}$, that is the value of θ in spherical coordinates as well. The value of ρ is $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + (\sqrt{3})^2 + 4^2} = \sqrt{20} = 2\sqrt{5}$. Finally, $\cos \phi = \frac{z}{\rho} = \frac{4}{2\sqrt{5}} = \frac{2}{\sqrt{5}}$, so $\phi = \cos^{-1}\left(\frac{2}{\sqrt{5}}\right)$. So the spherical coordinates of the cartesian point $(1, \sqrt{3}, 4)$ are $(\rho, \theta, \phi) = \left(2\sqrt{5}, \frac{\pi}{3}, \cos^{-1}\left(\frac{2}{\sqrt{5}}\right)\right)$.

41. In spherical coordinates, the solid E between the spheres $x^2 + y^2 + z^2 = 4$ and $x^2 + y^2 + z^2 = 1$ is described by $1 \leq \rho \leq 2$, $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \pi$. Then the volume V of the solid E is

$$\begin{aligned} V &= \iiint_E dV = \int_0^{2\pi} \int_0^\pi \int_1^2 \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta = \int_0^{2\pi} \int_0^\pi \sin \phi \cdot \left[\frac{\rho^3}{3}\right]_1^2 d\phi \, d\theta \\ &= \int_0^{2\pi} \int_0^\pi \sin \phi \cdot \left(\frac{8}{3} - \frac{1}{3}\right) d\phi \, d\theta = \frac{7}{3} \int_0^{2\pi} \int_0^\pi \sin \phi \, d\phi \, d\theta = \frac{7}{3} \int_0^{2\pi} [-\cos \phi]_0^\pi d\theta \\ &= \frac{7}{3} \int_0^{2\pi} (-\cos \pi + \cos 0) d\theta = \frac{7}{3} \int_0^{2\pi} (1 + 1) d\theta = \frac{14}{3} \int_0^{2\pi} d\theta \\ &= \frac{14}{3} [\theta]_0^{2\pi} = \frac{14}{3} (2\pi - 0) = \boxed{\frac{28\pi}{3} \text{ cubic units}}. \end{aligned}$$

42. In spherical coordinates, the solid E cut from the sphere $\rho = 4$ by the cone $\phi = \frac{\pi}{4}$ is described by

$0 \leq \rho \leq 4$, $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \frac{\pi}{4}$. Then the volume V of the solid E is

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^{2\pi} \int_0^{\pi/4} \int_0^4 \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta = \int_0^{2\pi} \int_0^{\pi/4} \sin \phi \cdot \left[\frac{\rho^3}{3} \right]_0^4 d\phi \, d\theta \\
 &= \int_0^{2\pi} \int_0^{\pi/4} \sin \phi \cdot \left(\frac{64}{3} - 0 \right) d\phi \, d\theta = \frac{64}{3} \int_0^{2\pi} \int_0^{\pi/4} \sin \phi \, d\phi \, d\theta = \frac{64}{3} \int_0^{2\pi} [-\cos \phi]_0^{\pi/4} d\theta \\
 &= \frac{64}{3} \int_0^{2\pi} \left(-\cos \frac{\pi}{4} + \cos 0 \right) d\theta = \frac{64}{3} \int_0^{2\pi} \left(-\frac{\sqrt{2}}{2} + 1 \right) d\theta = \frac{64}{3} \cdot \frac{2 - \sqrt{2}}{2} \int_0^{2\pi} d\theta \\
 &= \frac{32(2 - \sqrt{2})}{3} \cdot [\theta]_0^{2\pi} = \frac{32(2 - \sqrt{2})}{3} \cdot (2\pi - 0) = \boxed{\frac{64(2 - \sqrt{2})\pi}{3} \text{ cubic units}}.
 \end{aligned}$$

43. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $0 \leq z \leq \sqrt{4 - x^2 - y^2}$, $0 \leq y \leq \sqrt{4 - x^2}$, $0 \leq x \leq 2$; see the figures below. The limits of integration on z are $z = 0$, which is the xy -plane, and $z = \sqrt{4 - x^2 - y^2}$, or equivalently $x^2 + y^2 + z^2 = 4$, $z \geq 0$. So the solid E of integration is the portion of the ball of radius 2 lying in the first octant. In cylindrical coordinates, E is given by $0 \leq z \leq \sqrt{4 - r^2}$, $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the given integral can be converted to cylindrical coordinates as follows:

$$\begin{aligned}
 \int_0^2 \int_0^{\sqrt{4-x^2}} \int_0^{\sqrt{4-x^2-y^2}} \frac{z}{\sqrt{x^2+y^2}} \, dz \, dy \, dx &= \int_0^{\pi/2} \int_0^2 \int_0^{\sqrt{4-r^2}} \frac{z}{r} \cdot r \, dz \, dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^2 \int_0^{\sqrt{4-r^2}} z \, dz \, dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^2 \left[\frac{z^2}{2} \right]_0^{\sqrt{4-r^2}} dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^2 \left(\frac{4-r^2}{2} - 0 \right) dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^2 \left(2 - \frac{r^2}{2} \right) dr \, d\theta = \int_0^{\pi/2} \left[2r - \frac{r^3}{6} \right]_0^2 d\theta \\
 &= \int_0^{\pi/2} \left[\left(4 - \frac{8}{6} \right) - 0 \right] d\theta = \frac{8}{3} \int_0^{\pi/2} d\theta \\
 &= \frac{8}{3} [\theta]_0^{\pi/2} = \frac{8}{3} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{4\pi}{3}}.
 \end{aligned}$$

44. The solid E that is the part of the cylinder $r = 1$ lying in the first octant and below the plane $3x + 2y + 6z = 6$ is shown in figure (a) below. It is bounded between the surfaces $z = 0$ and

$z = 1 - \frac{x}{2} - \frac{y}{3} = 1 - \frac{r \cos \theta}{2} - \frac{r \sin \theta}{3}$. Its projection R onto the xy -plane is a quarter of a disk, as shown in figure (b) below; in cylindrical coordinates it is given by $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the volume V of the solid E is

$$\begin{aligned}
 V &= \iiint_E dV = \int_0^{\pi/2} \int_0^1 \int_0^{1-r \cos \theta/2 - r \sin \theta/3} r \, dz \, dr \, d\theta = \int_0^{\pi/2} \int_0^1 r[z]_0^{1-r \cos \theta/2 - r \sin \theta/3} \, dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^1 r \left[\left(1 - \frac{r \cos \theta}{2} - \frac{r \sin \theta}{3} \right) - 0 \right] \, dr \, d\theta = \int_0^{\pi/2} \int_0^1 \left(r - \frac{r^2 \cos \theta}{2} - \frac{r^2 \sin \theta}{3} \right) \, dr \, d\theta \\
 &= \int_0^{\pi/2} \left[\frac{r^2}{2} - \frac{r^3 \cos \theta}{6} - \frac{r^3 \sin \theta}{9} \right]_0^1 \, d\theta = \int_0^{\pi/2} \left[\left(\frac{1}{2} - \frac{\cos \theta}{6} - \frac{\sin \theta}{9} \right) - (0 - 0 - 0) \right] \, d\theta \\
 &= \int_0^{\pi/2} \left(\frac{1}{2} - \frac{\cos \theta}{6} - \frac{\sin \theta}{9} \right) \, d\theta = \left[\frac{\theta}{2} - \frac{\sin \theta}{6} + \frac{\cos \theta}{9} \right]_0^{\pi/2} \\
 &= \left(\frac{\pi}{4} - \frac{\sin \frac{\pi}{2}}{6} + \frac{\cos \frac{\pi}{2}}{9} \right) - \left(0 - \frac{\sin 0}{6} + \frac{\cos 0}{9} \right) = \left(\frac{\pi}{4} - \frac{1}{6} + 0 \right) - \left(0 - 0 + \frac{1}{9} \right) \\
 &= \boxed{\frac{\pi}{4} - \frac{5}{18} \text{ cubic units}}.
 \end{aligned}$$

(a)

(b)

45. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $0 \leq z \leq \sqrt{a^2 - x^2 - y^2}$, $0 \leq y \leq \sqrt{a^2 - x^2}$, $0 \leq x \leq a$; see the figures below. The limits of integration on z are $z = 0$, which is the xy -plane, and $z = \sqrt{a^2 - x^2 - y^2}$, or equivalently $x^2 + y^2 + z^2 = a^2$, $z \geq 0$. So the solid E of integration is the portion of the ball of radius a lying in the first octant. In cylindrical coordinates, E is given by $0 \leq z \leq \sqrt{a^2 - r^2}$, $0 \leq r \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the given integral can be converted to cylindrical coordinates as follows:

$$\begin{aligned}
 \int_0^a \int_0^{\sqrt{a^2 - x^2}} \int_0^{\sqrt{a^2 - x^2 - y^2}} dz \, dy \, dx &= \int_0^{\pi/2} \int_0^a \int_0^{\sqrt{a^2 - r^2}} r \, dz \, dr \, d\theta = \int_0^{\pi/2} \int_0^a r[z]_0^{\sqrt{a^2 - r^2}} \, dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^a r \left(\sqrt{a^2 - r^2} - 0 \right) \, dr \, d\theta = \int_0^{\pi/2} \int_0^a r \sqrt{a^2 - r^2} \, dr \, d\theta.
 \end{aligned}$$

To evaluate the “inside” integral $\int_0^a r \sqrt{a^2 - r^2} \, dr$, we make a substitution $u = a^2 - r^2$; then $du = -2r \, dr$, so $r \, dr = \frac{du}{-2}$. We also change the limits of integration: if $r = 0$, then $u = a^2 - 0^2 = a^2$; if $r = a$, then

$u = a^2 - r^2 = 0$. So the second integral becomes

$$\begin{aligned} \int_0^a r \sqrt{a^2 - r^2} dr &= \int_{a^2}^0 \sqrt{u} \left(\frac{du}{-2} \right) = -\frac{1}{2} \int_{a^2}^0 \sqrt{u} du = \frac{1}{2} \int_0^{a^2} u^{1/2} du \\ &= \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_0^{a^2} = \frac{1}{3} \left[(\sqrt{u})^3 \right]_0^{a^2} = \frac{1}{3} \left[(\sqrt{a^2})^3 - (\sqrt{0})^3 \right] = \frac{1}{3} (a^3 - 0) = \frac{a^3}{3}. \end{aligned}$$

Going back to the double integral, we obtain

$$\int_0^{\pi/2} \int_0^a r \sqrt{a^2 - r^2} dr d\theta = \int_0^{\pi/2} \frac{a^3}{3} d\theta = \frac{a^3}{3} [\theta]_0^{\pi/2} = \frac{a^3}{3} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi a^3}{6}}.$$

46. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $0 \leq z \leq \sqrt{a^2 - x^2 - y^2}$, $0 \leq y \leq \sqrt{a^2 - x^2}$, $0 \leq x \leq a$; see the figures in the solution to Problem 45 above. The limits of integration on z are $z = 0$, which is the xy -plane, and $z = \sqrt{a^2 - x^2 - y^2}$, or equivalently $x^2 + y^2 + z^2 = a^2$, $z \geq 0$. So the solid E of integration is the portion of the ball of radius a lying in the first octant. In spherical coordinates, E is given by $0 \leq \rho \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$, $0 \leq \phi \leq \frac{\pi}{2}$. Then the given integral can be converted to spherical coordinates as follows:

$$\begin{aligned} \int_0^a \int_0^{\sqrt{a^2 - x^2}} \int_0^{\sqrt{a^2 - x^2 - y^2}} dz dy dx &= \int_0^{\pi/2} \int_0^{\pi/2} \int_0^a \rho^2 \sin \phi d\rho d\phi d\theta \\ &= \int_0^{\pi/2} \int_0^{\pi/2} \sin \phi \cdot \left[\frac{\rho^3}{3} \right]_0^a d\phi d\theta \\ &= \int_0^{\pi/2} \int_0^{\pi/2} \sin \phi \cdot \left(\frac{a^3}{3} - 0 \right) d\phi d\theta \\ &= \frac{a^3}{3} \int_0^{\pi/2} \int_0^{\pi/2} \sin \phi d\phi d\theta = \frac{a^3}{3} \int_0^{\pi/2} [-\cos \phi]_0^{\pi/2} d\theta \\ &= \frac{a^3}{3} \int_0^{\pi/2} \left(-\cos \frac{\pi}{2} + \cos 0 \right) d\theta = \frac{a^3}{3} \int_0^{\pi/2} (-0 + 1) d\theta \\ &= \frac{a^3}{3} \int_0^{\pi/2} d\theta = \frac{a^3}{3} [\theta]_0^{\pi/2} = \frac{a^3}{3} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi a^3}{6}}. \end{aligned}$$

47. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $0 \leq z \leq \sqrt{16 - x^2 - y^2}$, $-\sqrt{4 - y^2} \leq x \leq \sqrt{4 - y^2}$, $-2 \leq y \leq 2$; see the figures below. The limits of integration on z are $z = 0$, which is the xy -plane, and $z = \sqrt{16 - x^2 - y^2}$, or equivalently $x^2 + y^2 + z^2 = 16$, $z \geq 0$, which is the upper hemisphere of radius 4. The region R in the xy -plane is the disk of radius 2 centered at the origin. So the solid E of integration is the portion of the ball of radius 4 lying within the cylinder $x^2 + y^2 = 4$ and above the xy -plane. In cylindrical coordinates, E

is given by $0 \leq z \leq \sqrt{16-r^2}$, $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$. Then the given integral can be converted to cylindrical coordinates as follows:

$$\begin{aligned} \int_{-2}^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} \int_0^{\sqrt{16-x^2-y^2}} dz \, dx \, dy &= \int_0^{2\pi} \int_0^2 \int_0^{\sqrt{16-r^2}} r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^2 r[z]_0^{\sqrt{16-r^2}} \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^2 r(\sqrt{16-r^2} - 0) \, dr \, d\theta = \int_0^{2\pi} \int_0^2 r\sqrt{16-r^2} \, dr \, d\theta. \end{aligned}$$

To evaluate the “inside” integral $\int_0^2 r\sqrt{16-r^2} \, dr$, we make a substitution $u = 16-r^2$; then $du = -2r \, dr$, so $r \, dr = \frac{du}{-2}$. We also change the limits of integration: if $r = 0$, then $u = 16 - 0^2 = 16$; if $r = 2$, then $u = 16 - 2^2 = 12$. So the second integral becomes

$$\begin{aligned} \int_0^2 r\sqrt{16-r^2} \, dr &= \int_{16}^{12} \sqrt{u} \left(\frac{du}{-2} \right) = -\frac{1}{2} \int_{16}^{12} \sqrt{u} \, du = \frac{1}{2} \int_{12}^{16} u^{1/2} \, du = \frac{1}{2} \left[\frac{u^{3/2}}{3/2} \right]_{12}^{16} \\ &= \frac{1}{3} \left[(\sqrt{u})^3 \right]_{12}^{16} = \frac{1}{3} \left[(\sqrt{16})^3 - (\sqrt{12})^3 \right] = \frac{1}{3} (64 - 24\sqrt{3}) = \frac{64}{3} - 8\sqrt{3}. \end{aligned}$$

Going back to the double integral, we obtain

$$\begin{aligned} \int_0^{2\pi} \int_0^2 r\sqrt{16-r^2} \, dr \, d\theta &= \int_0^{2\pi} \left(\frac{64}{3} - 8\sqrt{3} \right) d\theta = \left(\frac{64}{3} - 8\sqrt{3} \right) [\theta]_0^{2\pi} \\ &= \left(\frac{64}{3} - 8\sqrt{3} \right) (2\pi - 0) = \boxed{\pi \left(\frac{128}{3} - 16\sqrt{3} \right)}. \end{aligned}$$

48. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $\sqrt{x^2 + y^2} \leq z \leq \sqrt{2 - x^2 - y^2}$, $-\sqrt{1 - x^2} \leq y \leq \sqrt{1 - x^2}$, $0 \leq x \leq 1$; see the figures below. The limits of integration on z are from $z = \sqrt{x^2 + y^2}$, which is the cone $\phi = \frac{\pi}{4}$, to $z = \sqrt{2 - x^2 - y^2}$, which is a sphere of radius $\sqrt{2}$. In spherical coordinates, E is given by $0 \leq \rho \leq \sqrt{2}$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$, $0 \leq \phi \leq \frac{\pi}{4}$.

Then the given integral can be converted to spherical coordinates as follows:

$$\begin{aligned}
 \int_0^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{\sqrt{x^2+y^2}}^{\sqrt{2-x^2-y^2}} dz \, dy \, dx &= \int_{-\pi/2}^{\pi/2} \int_0^{\pi/4} \int_0^{\sqrt{2}} \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta \\
 &= \int_{-\pi/2}^{\pi/2} \int_0^{\pi/4} \sin \phi \cdot \left[\frac{\rho^3}{3} \right]_0^{\sqrt{2}} d\phi \, d\theta \\
 &= \int_{-\pi/2}^{\pi/2} \int_0^{\pi/4} \sin \phi \cdot \left(\frac{2\sqrt{2}}{3} - 0 \right) d\phi \, d\theta \\
 &= \frac{2\sqrt{2}}{3} \int_{-\pi/2}^{\pi/2} [-\cos \phi]_0^{\pi/4} d\theta \\
 &= \frac{2\sqrt{2}}{3} \int_{-\pi/2}^{\pi/2} \left(-\cos \frac{\pi}{4} + \cos 0 \right) d\theta \\
 &= \frac{2\sqrt{2}}{3} \int_{-\pi/2}^{\pi/2} \left(-\frac{\sqrt{2}}{2} + 1 \right) d\theta = \frac{2\sqrt{2}}{3} \cdot \frac{2-\sqrt{2}}{2} \cdot [\theta]_{-\pi/2}^{\pi/2} \\
 &= \frac{2\sqrt{2}-2}{3} \cdot \left(\frac{\pi}{2} + \frac{\pi}{2} \right) = \boxed{\frac{(2\sqrt{2}-2)\pi}{3}}.
 \end{aligned}$$

49. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $0 \leq z \leq 4$, $-\sqrt{2-x^2} \leq y \leq \sqrt{2-x^2}$, $-\sqrt{2} \leq x \leq \sqrt{2}$; see the figures below. The region R in the xy -plane is the disk of radius $\sqrt{2}$ centered at the origin. So the solid E of integration is the portion of a vertical cylinder of radius $\sqrt{2}$ contained between the planes $z = 0$ and $z = 4$. In cylindrical coordinates, E is given by $0 \leq z \leq 4$, $0 \leq r \leq \sqrt{2}$, $0 \leq \theta \leq 2\pi$. Then the given integral can be converted to cylindrical coordinates as follows:

$$\begin{aligned}
 \int_{-\sqrt{2}}^{\sqrt{2}} \int_{-\sqrt{2-x^2}}^{\sqrt{2-x^2}} \int_0^4 (x^2 + y^2)z \, dz \, dy \, dx &= \int_0^{2\pi} \int_0^{\sqrt{2}} \int_0^4 r^2 z \cdot r \, dz \, dr \, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} \int_0^4 r^3 z \, dz \, dr \, d\theta \\
 &= \int_0^{2\pi} \int_0^{\sqrt{2}} r^3 \left[\frac{z^2}{2} \right]_0^4 dr \, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} r^3 (8 - 0) \, dr \, d\theta \\
 &= 8 \int_0^{2\pi} \int_0^{\sqrt{2}} r^3 \, dr \, d\theta = 8 \int_0^{2\pi} \left[\frac{r^4}{4} \right]_0^{\sqrt{2}} d\theta \\
 &= 8 \int_0^{2\pi} (1 - 0) \, d\theta = 8 \int_0^{2\pi} d\theta = 8[\theta]_0^{2\pi} = 8(2\pi - 0) = \boxed{16\pi}.
 \end{aligned}$$

50. The solid E of integration can be described by the inequalities $0 \leq y \leq \sqrt{1-x^2}$, $0 \leq x \leq 1$, $0 \leq z \leq 1$; see the figure below. It is part of a vertical cylinder of radius 1 contained between the planes $z = 0$ and $z = 1$ in the first octant. In cylindrical coordinates, E is given by $0 \leq z \leq 1$, $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$. Then the given integral can be converted to cylindrical coordinates as follows:

$$\begin{aligned}
 \int_0^1 \int_0^1 \int_0^{\sqrt{1-x^2}} dy \, dx \, dz &= \int_0^{\pi/2} \int_0^1 \int_0^1 r \, dz \, dr \, d\theta = \int_0^{\pi/2} \int_0^1 r[z]_0^1 \, dr \, d\theta \\
 &= \int_0^{\pi/2} \int_0^1 r(1-0) \, dr \, d\theta = \int_0^{\pi/2} \int_0^1 r \, dr \, d\theta = \int_0^{\pi/2} \left[\frac{r^2}{2} \right]_0^1 d\theta \\
 &= \int_0^{\pi/2} \left(\frac{1}{2} - 0 \right) d\theta = \frac{1}{2} \int_0^{\pi/2} d\theta = \frac{1}{2} [\theta]_0^{\pi/2} = \frac{1}{2} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi}{4}}.
 \end{aligned}$$

51. The solid E of integration can be described by the inequalities $\frac{h}{a}\sqrt{x^2+y^2} \leq z \leq \sqrt{a^2-x^2-y^2}$, $0 \leq y \leq \sqrt{\frac{a^4}{a^2+h^2}-x^2}$, $0 \leq x \leq \frac{a^2}{\sqrt{a^2+h^2}}$; see the figure below. The limits of integration on z are from $z = \frac{h}{a}\sqrt{x^2+y^2}$, which is the upper nappe of the cone $\phi = \tan^{-1}\left(\frac{a}{h}\right)$, to $z = \sqrt{a^2-x^2-y^2}$, which is the upper half of the sphere of radius a ; and since $x \geq 0$ and $y \geq 0$, the entire solid lies in the first octant. The trace of the line of intersection of the cone and the sphere can be found by setting

their equations equal to each other:

$$\begin{aligned}\sqrt{a^2 - x^2 - y^2} &= \frac{h}{a} \sqrt{x^2 + y^2} \\ a^2 - x^2 - y^2 &= \frac{h^2}{a^2} (x^2 + y^2) \\ a^2 &= \frac{h^2}{a^2} (x^2 + y^2) + x^2 + y^2 \\ a^2 &= \left(\frac{h^2}{a^2} + 1 \right) (x^2 + y^2) \\ x^2 + y^2 &= \frac{a^2}{\frac{h^2}{a^2} + 1} \\ x^2 + y^2 &= \frac{a^4}{h^2 + a^2}\end{aligned}$$

which is a circle of radius $\frac{a^2}{\sqrt{h^2 + a^2}}$ (or rather the first-quadrant quarter of this circle, since $x \geq 0$ and $y \geq 0$), in agreement with the given limits of integration. If we denote $\alpha = \tan^{-1} \left(\frac{a}{h} \right)$ for brevity, then in spherical coordinates E is given by $0 \leq \rho \leq a$, $0 \leq \theta \leq \frac{\pi}{2}$, $0 \leq \phi \leq \alpha$. Then the given integral can be converted to spherical coordinates as follows:

$$\begin{aligned}\int_0^{\frac{a^2}{\sqrt{a^2+h^2}}} \int_0^{\sqrt{\frac{a^4}{a^2+h^2}-x^2}} \int_{\frac{h}{a}\sqrt{x^2+y^2}}^{\sqrt{a^2-x^2-y^2}} dz \, dy \, dx &= \int_0^{\pi/2} \int_0^\alpha \int_0^a \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta \\ &= \int_0^{\pi/2} \int_0^\alpha \sin \phi \cdot \left[\frac{\rho^3}{3} \right]_0^a d\phi \, d\theta \\ &= \int_0^{\pi/2} \int_0^\alpha \sin \phi \cdot \left(\frac{a^3}{3} - 0 \right) d\phi \, d\theta \\ &= \frac{a^3}{3} \int_0^{\pi/2} [-\cos \phi]_0^\alpha d\theta \\ &= \frac{a^3}{3} \int_0^{\pi/2} (-\cos \alpha + \cos 0) d\theta \\ &= \frac{a^3}{3} (1 - \cos \alpha) \int_0^{\pi/2} d\theta = \frac{a^3}{3} (1 - \cos \alpha) [\theta]_0^{\pi/2} \\ &= \frac{a^3}{3} (1 - \cos \alpha) \left(\frac{\pi}{2} - 0 \right) = \frac{\pi a^3}{6} (1 - \cos \alpha).\end{aligned}$$

To obtain the final answer, recall that we denoted $\alpha = \tan^{-1} \left(\frac{a}{h} \right)$; notice that α lies in the first quadrant because $\tan \alpha = \frac{a}{h} > 0$. Then $\sec^2 \alpha = 1 + \tan^2 \alpha = 1 + \frac{a^2}{h^2} = \frac{h^2 + a^2}{h^2}$, so $\sec \alpha = \sqrt{\frac{h^2 + a^2}{h^2}} = \frac{\sqrt{h^2 + a^2}}{h}$, and $\cos \alpha = \frac{1}{\sec \alpha} = \frac{h}{\sqrt{h^2 + a^2}}$. Substituting this into the last expression, we obtain

$$\frac{\pi a^3}{6} (1 - \cos \alpha) = \boxed{\frac{\pi a^3}{6} \left(1 - \frac{h}{\sqrt{h^2 + a^2}} \right)}.$$

52. The region R associated with the double integral $\int_0^1 \int_0^{\sqrt{1-x^2}} (x^2 + y^2)^{3/2} dy dx$ is enclosed between $y = 0$ and $y = \sqrt{1-x^2}$, where $0 \leq x \leq 1$. This is the first-quadrant quarter of the disk of radius 1 centered at the origin. In polar coordinates R is given by $0 \leq r \leq 1$, $0 \leq \theta \leq \frac{\pi}{2}$. Also, in the integrand we can simplify $(x^2 + y^2)^{3/2} = (r^2)^{3/2} = r^3$. Then

$$\begin{aligned} \int_0^1 \int_0^{\sqrt{1-x^2}} (x^2 + y^2)^{3/2} dy dx &= \int_0^{\pi/2} \int_0^1 r^3 \cdot r dr d\theta = \int_0^{\pi/2} \int_0^1 r^4 dr d\theta = \int_0^{\pi/2} \left[\frac{r^5}{5} \right]_0^1 d\theta \\ &= \int_0^{\pi/2} \left(\frac{1}{5} - 0 \right) d\theta = \frac{1}{5} [\theta]_0^{\pi/2} = \frac{1}{5} \left(\frac{\pi}{2} - 0 \right) = \boxed{\frac{\pi}{10}}. \end{aligned}$$

53. The solid E of integration and its projection R onto the xy -plane can be described by the inequalities $\sqrt{x^2 + y^2} \leq z \leq \sqrt{2-x^2-y^2}$, $-\sqrt{1-y^2} \leq x \leq \sqrt{1-y^2}$, $-1 \leq y \leq 1$; see the figure below. The limits of integration on z are from $z = \sqrt{x^2 + y^2}$, which is the cone $\phi = \frac{\pi}{4}$, to $z = \sqrt{2-x^2-y^2}$, which is a sphere of radius $\sqrt{2}$. In spherical coordinates, E is given by $0 \leq \rho \leq \sqrt{2}$, $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \frac{\pi}{4}$. Then the given integral can be converted to spherical coordinates as follows:

$$\begin{aligned} \int_{-1}^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} \int_{\sqrt{x^2+y^2}}^{\sqrt{2-x^2-y^2}} dz dx dy &= \int_0^{2\pi} \int_0^{\pi/4} \int_0^{\sqrt{2}} \rho^2 \sin \phi d\rho d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/4} \sin \phi \cdot \left[\frac{\rho^3}{3} \right]_0^{\sqrt{2}} d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/4} \sin \phi \cdot \left(\frac{2\sqrt{2}}{3} - 0 \right) d\phi d\theta \\ &= \frac{2\sqrt{2}}{3} \int_0^{2\pi} [-\cos \phi]_0^{\pi/4} d\theta \\ &= \frac{2\sqrt{2}}{3} \int_0^{2\pi} \left(-\cos \frac{\pi}{4} + \cos 0 \right) d\theta \\ &= \frac{2\sqrt{2}}{3} \int_0^{2\pi} \left(-\frac{\sqrt{2}}{2} + 1 \right) d\theta = \frac{2\sqrt{2}}{3} \cdot \frac{2-\sqrt{2}}{2} \cdot [\theta]_0^{2\pi} \\ &= \frac{2\sqrt{2}-2}{3} \cdot (2\pi-0) = \boxed{\frac{4(\sqrt{2}-1)\pi}{3}}. \end{aligned}$$

54. The limits of integration of the iterated integral $\int_0^1 \int_y^1 (x^2 + 1)^{2/3} dx dy$ describe the region R bounded between $x = y$ and $x = 1$, where $0 \leq y \leq 1$. This is a triangular region, as shown in the figure below. Observe that R is also an x -simple region: it is bounded between $y = 0$ and $y = x$, where $0 \leq x \leq 1$. So according to Fubini's Theorem,

$$\begin{aligned} \int_0^1 \int_y^1 (x^2 + 1)^{2/3} dx dy &= \iint_R (x^2 + 1)^{2/3} dA = \int_0^1 \int_0^x (x^2 + 1)^{2/3} dy dx = \int_0^1 (x^2 + 1)^{2/3} [y]_0^x dx \\ &= \int_0^1 (x^2 + 1)^{2/3} (x - 0) dx = \int_0^1 (x^2 + 1)^{2/3} x dx. \end{aligned}$$

In this integral we make a substitution $u = x^2 + 1$; then $du = 2x dx$, so $x dx = \frac{du}{2}$. We also change the limits of integration: if $x = 0$, then $u = 0^2 + 1 = 1$; if $x = 1$, then $u = 1^2 + 1 = 2$. So

$$\begin{aligned} \int_0^1 (x^2 + 1)^{2/3} x dx &= \int_1^2 u^{2/3} \frac{du}{2} = \frac{1}{2} \int_1^2 u^{2/3} du = \frac{1}{2} \left[\frac{u^{5/3}}{5/3} \right]_1^2 \\ &= \frac{3}{10} \left[u^{5/3} \right]_1^2 = \frac{3}{10} (2^{5/3} - 1^{5/3}) = \boxed{\frac{3(2^{5/3} - 1)}{10}}. \end{aligned}$$

55. The partial derivatives of the given change of variable functions $x = e^{u+v}$ and $y = e^{v-u}$ are

$$\frac{\partial x}{\partial u} = e^{u+v}, \quad \frac{\partial x}{\partial v} = e^{u+v}, \quad \frac{\partial y}{\partial u} = -e^{v-u}, \quad \frac{\partial y}{\partial v} = e^{v-u}.$$

Then the Jacobian of x, y with respect to u, v is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} e^{u+v} & e^{u+v} \\ -e^{v-u} & e^{v-u} \end{vmatrix} = e^{u+v} \cdot e^{v-u} - e^{u+v} \cdot (-e^{v-u}) = \boxed{2e^{2v}}.$$

56. The partial derivatives of the given change of variable functions $x = u + 3v$ and $y = 2u - v$ are

$$\frac{\partial x}{\partial u} = 1, \quad \frac{\partial x}{\partial v} = 3, \quad \frac{\partial y}{\partial u} = 2, \quad \frac{\partial y}{\partial v} = -1.$$

Then the Jacobian of x, y with respect to u, v is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & 3 \\ 2 & -1 \end{vmatrix} = 1 \cdot (-1) - 3 \cdot 2 = \boxed{-7}.$$

57. For the given change of variable functions $x = u^2$, $y = 3v$, and $z = u + w$, the Jacobian of x, y, z with respect to u, v, w is

$$\frac{\partial(x, y, z)}{\partial(u, v, w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 2u & 0 & 0 \\ 0 & 3 & 0 \\ 1 & 0 & 1 \end{vmatrix} = 2u \cdot 3 \cdot 1 = \boxed{6u}.$$

58. The region R enclosed by $x - 2y = 1$, $x - 2y = 3$, $2x + 3y = 1$, and $2x + 3y = 2$ is shown in figure (a) below. With the indicated change of variables $u = x - 2y$ and $v = 2x + 3y$, the equations $x - 2y = 1$ and $x - 2y = 3$ become $u = 1$ and $u = 3$, while $2x + 3y = 1$ and $2x + 3y = 2$ become $v = 1$ and $v = 2$. So the region $R^\#$ is the rectangle $1 \leq u \leq 3$, $1 \leq v \leq 2$, shown in figure (b) below.

(a)

(b)

Solving the change of variable equations for x and y gives $x = \frac{3u + 2v}{7}$ and $y = \frac{v - 2u}{7}$. Then the Jacobian of x, y with respect to u, v is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{3}{7} & \frac{2}{7} \\ \frac{2}{7} & \frac{1}{7} \end{vmatrix} = \frac{3}{7} \cdot \frac{1}{7} - \frac{2}{7} \cdot \left(-\frac{2}{7}\right) = \frac{1}{7},$$

and $\left| \frac{\partial(x, y)}{\partial(u, v)} \right| = \left| \frac{1}{7} \right| = \frac{1}{7}$. Then in terms of the new variables u, v , the integral becomes

$$\begin{aligned} \iint_R y^2 dx dy &= \iint_{R^\#} \left(\frac{v - 2u}{7} \right)^2 \cdot \frac{1}{7} du dv = \frac{1}{343} \int_1^2 \int_1^3 (v^2 - 4uv + 4u^2) du dv \\ &= \frac{1}{343} \int_1^2 \left[uv^2 - 2u^2v + \frac{4u^3}{3} \right]_1^3 dv = \frac{1}{343} \int_1^2 \left[(3v^2 - 18v + 36) - \left(v^2 - 2v + \frac{4}{3} \right) \right] dv \\ &= \frac{1}{343} \int_1^2 \left(2v^2 - 16v + \frac{104}{3} \right) dv = \frac{1}{343} \left[\frac{2v^3}{3} - 8v^2 + \frac{104v}{3} \right]_1^2 \\ &= \frac{1}{343} \left[\left(\frac{16}{3} - 32 + \frac{208}{3} \right) - \left(\frac{2}{3} - 8 + \frac{104}{3} \right) \right] = \frac{1}{343} \cdot \frac{46}{3} = \boxed{\frac{46}{1029}}. \end{aligned}$$

59. The region R enclosed by $x + y = 2$, $x + y = 5$, $x - 2y = -1$, and $x - 2y = 3$ is shown in figure (a) below. With the indicated change of variables $u = x + y$ and $v = x - 2y$, the equations $x + y = 2$ and $x + y = 5$ become $u = 2$ and $u = 5$, while $x - 2y = -1$ and $x - 2y = 3$ become $v = -1$ and $v = 3$. So $R^\#$ is the rectangular region $2 \leq u \leq 5$, $-1 \leq v \leq 3$, shown in figure (b) below.

(a)

(b)

Solving the change of variable equations for x and y gives $x = \frac{2u + v}{3}$ and $y = \frac{u - v}{3}$. Then the Jacobian of x, y with respect to u, v is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{2}{3} & \frac{1}{3} \\ \frac{1}{3} & -\frac{1}{3} \end{vmatrix} = \frac{2}{3} \cdot \left(-\frac{1}{3}\right) - \frac{1}{3} \cdot \frac{1}{3} = -\frac{1}{3},$$

and $\left| \frac{\partial(x, y)}{\partial(u, v)} \right| = \left| -\frac{1}{3} \right| = \frac{1}{3}$. Then in terms of the new variables u, v , the integral becomes

$$\begin{aligned} \iint_R (x + y)^3 dx dy &= \iint_{R^\#} u^3 \cdot \frac{1}{3} du dv = \frac{1}{3} \int_{-1}^3 \int_2^5 u^3 du dv = \frac{1}{3} \int_{-1}^3 \left[\frac{u^4}{4} \right]_2^5 dv \\ &= \frac{1}{3} \int_{-1}^3 \left(\frac{625}{4} - 4 \right) dv = \frac{1}{3} \cdot \frac{609}{4} \int_{-1}^3 dv = \frac{203}{4} [v]_{-1}^3 = \frac{203}{4} (3 + 1) = \boxed{203}. \end{aligned}$$

60. The region R enclosed by $2x + y = 0$, $2x + y = 3$, $x - y = 0$, and $x - y = 2$ is shown in figure (a) below. We will use the change of variables $u = 2x + y$ and $v = x - y$. The equations $2x + y = 0$ and $2x + y = 3$ become $u = 0$ and $u = 3$, while $x - y = 0$ and $x - y = 2$ become $v = 0$ and $v = 2$. So $R^\#$ is the rectangular region $0 \leq u \leq 3$, $0 \leq v \leq 2$, shown in figure (b) below.

Solving the change of variable equations for x and y gives $x = \frac{u + v}{3}$ and $y = \frac{u - 2v}{3}$. Then the Jacobian of x, y with respect to u, v is

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{3} & \frac{1}{3} \\ \frac{1}{3} & -\frac{2}{3} \end{vmatrix} = \frac{1}{3} \cdot \left(-\frac{2}{3}\right) - \frac{1}{3} \cdot \frac{1}{3} = -\frac{1}{3},$$

and $\left| \frac{\partial(x,y)}{\partial(u,v)} \right| = \left| -\frac{1}{3} \right| = \frac{1}{3}$. Then in terms of the new variables u, v , the integral becomes

$$\begin{aligned}
 \iint_R xy \, dx \, dy &= \iint_{R^\#} \frac{u+v}{3} \cdot \frac{u-2v}{3} \cdot \frac{1}{3} \, du \, dv = \frac{1}{27} \int_0^2 \int_0^3 (u^2 - uv - 2v^2) \, du \, dv \\
 &= \frac{1}{27} \int_0^2 \left[\frac{u^3}{3} - \frac{u^2 v}{2} - 2uv^2 \right]_0^3 \, dv = \frac{1}{27} \int_0^2 \left[\left(9 - \frac{9v}{2} - 6v^2 \right) - 0 \right] \, dv \\
 &= \frac{1}{27} \int_0^2 \left(9 - \frac{9v}{2} - 6v^2 \right) \, dv = \frac{1}{27} \left[9v - \frac{9v^2}{4} - 2v^3 \right]_0^2 \\
 &= \frac{1}{27} [(18 - 9 - 16) - 0] = \frac{1}{27} \cdot (-7) = \boxed{-\frac{7}{27}}.
 \end{aligned}$$

61. The solid E enclosed by the ellipsoid $\frac{x^2}{4} + \frac{y^2}{9} + z^2 = 1$ is shown in the figure below. Solving the given change of variables $u = \frac{x}{2}$, $v = \frac{y}{3}$, $w = z$ for x, y , and z gives $x = 2u$, $y = 3v$, and $z = w$. Then the equation of the ellipsoid becomes $\frac{(2u)^2}{4} + \frac{(3v)^2}{9} + w^2 = 1$ or just $u^2 + v^2 + w^2 = 1$, so that $E^\#$ is the ball of radius 1 centered at the origin.

The Jacobian of the given transformation is

$$\frac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 1 \end{vmatrix} = 2 \cdot 3 \cdot 1 = 6,$$

and $\left| \frac{\partial(x, y, z)}{\partial(u, v, w)} \right| = |6| = 6$. Then in terms of the new variables u, v, w , the integral becomes

$$\iiint_E xz^2 dx dy dz = \iiint_{E^\#} 2u \cdot w^2 \cdot 6 dv du dw = 12 \iiint_{E^\#} uw^2 dv du dw.$$

To perform the integration, use spherical coordinates in the uvw -space:

$$\begin{aligned} 12 \iiint_{E^\#} uw^2 dv du dw &= 12 \int_0^1 \int_0^\pi \int_0^{2\pi} \rho \cos \theta \sin \phi \cdot (\rho \cos \phi)^2 \cdot \rho^2 \sin \phi d\theta d\phi d\rho \\ &= 12 \int_0^1 \int_0^\pi \int_0^{2\pi} \rho^5 \cos \theta \sin^2 \phi \cos^2 \phi d\theta d\phi d\rho \\ &= 12 \int_0^1 \int_0^\pi \rho^5 \sin^2 \phi \cos^2 \phi \cdot [\sin \theta]_0^{2\pi} d\phi d\rho \\ &= 12 \int_0^1 \int_0^\pi \rho^5 \sin^2 \phi \cos^2 \phi \cdot (\sin 2\pi - \sin 0) d\phi d\rho \\ &= 12 \int_0^1 \int_0^\pi \rho^5 \sin^2 \phi \cos^2 \phi \cdot (0 - 0) d\phi d\rho \\ &= 12 \int_0^1 \int_0^\pi 0 d\phi d\rho = \boxed{0}. \end{aligned}$$

62. Let E be the solid enclosed by the surface $z = xy$, the xy -plane, and the vertical cylinder whose base in the xy -plane is the triangular region R with vertices $(0, 0, 0)$, $(2, 0, 0)$, and $(0, 1, 0)$; the solid E and the region R are shown in the figures below. Using the given mass density $\rho(x, y, z) = x + y$, we find the mass of the solid E as follows:

$$\begin{aligned} M &= \iiint_E \rho(x, y, z) dV = \int_0^1 \int_0^{2-2y} \int_0^{xy} (x + y) dz dx dy = \int_0^1 \int_0^{2-2y} (x + y) [z]_0^{xy} dx dy \\ &= \int_0^1 \int_0^{2-2y} (x + y)(xy - 0) dx dy = \int_0^1 \int_0^{2-2y} (x^2 y + xy^2) dx dy = \int_0^1 \left[\frac{x^3 y}{3} + \frac{x^2 y^2}{2} \right]_0^{2-2y} dy \\ &= \int_0^1 \left[\left(\frac{(2-2y)^3 y}{3} + \frac{(2-2y)^2 y^2}{2} \right) - 0 \right] dy = \int_0^1 \left(\frac{8y}{3} - 6y^2 + 4y^3 - \frac{2y^4}{3} \right) dy \\ &= \left[\frac{4y^2}{3} - 2y^3 + y^4 - \frac{2y^5}{15} \right]_0^1 = \left(\frac{4}{3} - 2 + 1 - \frac{2}{15} \right) - 0 = \boxed{\frac{1}{5}}. \end{aligned}$$

(b)

Chapter 15: Vector Calculus

15.1: Vector Fields

Concepts and Vocabulary

1. A *vector field* is a function that associates a vector to a point in the plane or to a point in space. See the introduction to objective 1.
2. False. The right-hand side as written is a number, not a vector. A vector field could be defined as $F(x, y, z) = P(x, y, z)\mathbf{i} + Q(x, y, z)\mathbf{j} + R(x, y, z)\mathbf{k}$.
3. The range of $\mathbf{F}$ is a set of *vectors* in the plane. See objective 1.
4. True. See Example 6.

Skill Building

10.

11.

12.

4

13.

14.

15.

The vector associated with any point except the origin is a unit vector pointing away from the origin. The vector field is not defined at the origin.

16.

The vector associated with any point except the origin is a unit vector pointing towards the origin. The vector field is not defined at the origin.

Applications and Extensions

17. Since $\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}$, and

$$f_x(x, y) = \frac{\partial}{\partial x}(x \sin y + \cos y) = \sin y, \quad f_y(x, y) = \frac{\partial}{\partial y}(x \sin y + \cos y) = x \cos y - \sin y,$$

the gradient is

$$\nabla f(x, y) = \boxed{\sin y \mathbf{i} + (x \cos y - \sin y) \mathbf{j}}.$$

18. Since $\nabla f(x, y) = f_x(x, y)\mathbf{i} + f_y(x, y)\mathbf{j}$, and

$$f_x(x, y) = \frac{\partial}{\partial x}(xe^y) = e^y, \quad f_y(x, y) = \frac{\partial}{\partial y}(xe^y) = xe^y,$$

the gradient is

$$\nabla f(x, y) = \boxed{e^y \mathbf{i} + xe^y \mathbf{j}}.$$

19. Since $\nabla f(x, y, z) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k}$, and

$$\begin{aligned} f_x(x, y, z) &= \frac{\partial}{\partial x}(x^2y + xy + y^2z) = 2xy + y, \\ f_y(x, y, z) &= \frac{\partial}{\partial y}(x^2y + xy + y^2z) = x^2 + x + 2yz, \\ f_z(x, y, z) &= \frac{\partial}{\partial z}(x^2y + xy + y^2z) = y^2, \end{aligned}$$

the gradient is

$$\nabla f(x, y) = \boxed{(2xy + y)\mathbf{i} + (x^2 + x + 2yz)\mathbf{j} + y^2\mathbf{k}}.$$

20. Since $\nabla f(x, y, z) = f_x(x, y, z)\mathbf{i} + f_y(x, y, z)\mathbf{j} + f_z(x, y, z)\mathbf{k}$, and

$$\begin{aligned} f_x(x, y, z) &= \frac{\partial}{\partial x}(x^2y + xyz^2) = 2xy + yz^2, \\ f_y(x, y, z) &= \frac{\partial}{\partial y}(x^2y + xyz^2) = x^2 + xz^2, \\ f_z(x, y, z) &= \frac{\partial}{\partial z}(x^2y + xyz^2) = 2xyz, \end{aligned}$$

the gradient is

$$\nabla f(x, y) = \boxed{(2xy + yz^2)\mathbf{i} + (x^2 + xz^2)\mathbf{j} + 2xyz\mathbf{k}}.$$

21. (a) From plane geometry, we know that a tangent to a circle is perpendicular to the radius at that point. At a point (x, y) in the plane, the radius vector of the circle centered at the origin and passing through (x, y) is $x\mathbf{i} + y\mathbf{j}$, and the vector field there is $\mathbf{F}(x, y) = -y\mathbf{i} + x\mathbf{j}$. Then

$$(x\mathbf{i} + y\mathbf{j}) \cdot (-y\mathbf{i} + x\mathbf{j}) = -xy + xy = 0,$$

so that the vector field is perpendicular to the radial vectors of the circle, so they are tangent to the unit circle.

- (b) The radius of the circle in part (a) is $\sqrt{x^2 + y^2}$, and the magnitude of the vector field is $\|\mathbf{F}\| = \sqrt{(-y)^2 + x^2} = \sqrt{x^2 + y^2}$. The two are equal.

22. Place the origin at the center of the large object. Then a point r meters away has coordinates (x, y, z) , where $r = \sqrt{x^2 + y^2 + z^2}$. Then

$$u(x, y, z) = -\frac{Gm}{r} = -\frac{Gm}{\sqrt{x^2 + y^2 + z^2}} = -Gm(x^2 + y^2 + z^2)^{-1/2}.$$

Taking partial derivatives gives

$$\begin{aligned} u_x(x, y, z) &= -\frac{1}{2} \left(-Gm(x^2 + y^2 + z^2)^{-3/2} \right) \cdot 2x = -xGm(x^2 + y^2 + z^2)^{-3/2} = -\frac{Gm}{r^3}x \\ u_y(x, y, z) &= -\frac{1}{2} \left(-Gm(x^2 + y^2 + z^2)^{-3/2} \right) \cdot 2y = -yGm(x^2 + y^2 + z^2)^{-3/2} = -\frac{Gm}{r^3}y \\ u_z(x, y, z) &= -\frac{1}{2} \left(-Gm(x^2 + y^2 + z^2)^{-3/2} \right) \cdot 2z = -zGm(x^2 + y^2 + z^2)^{-3/2} = -\frac{Gm}{r^3}z. \end{aligned}$$

Then

$$\begin{aligned}
 \nabla u &= u_x(x, y, z)\mathbf{i} + u_y(x, y, z)\mathbf{j} + u_z(x, y, z)\mathbf{k} \\
 &= -\frac{Gm}{r^3}x\mathbf{i} - \frac{Gm}{r^3}y\mathbf{j} - \frac{Gm}{r^3}z\mathbf{k} \\
 &= -\frac{Gm}{r^3}(x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) \\
 &= -\frac{Gm}{r^3}\mathbf{r} = \mathbf{g}.
 \end{aligned}$$

15.2: Line Integrals

Concepts and Vocabulary

1. True. This is the content of the Value of a Line Integral Theorem.
2. $\int_a^b f(x(t), y(t)) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$. See the Value of a Line Integral Theorem.
3. False. See Example 2. This fact is not proved in the text, but it is asserted.
4. $M = \int_C \rho(x, y) ds$. See Equation (2) and Example 3.
5. False. Reversing the direction of the curve negates the value of the line integral, so that $\int_{-C} (P dx + Q dy) = -\int_C (P dx + Q dy)$.
6. True. See Objective 4.
7. $\int_C (P dx + Q dy) = \int_{C_1} (P dx + Q dy) + \int_{C_1} (P dx + Q dy) + \cdots + \int_{C_n} (P dx + Q dy)$. See the first definition in Objective 4.
8. False. The factor of $x(t)$ in the right-hand side should be $x'(t)$:

$$\int_C P(x, y, z) dx = \int_a^b P(x(t), y(t), z(t))x'(t) dt.$$

Skill Building

9. With the given parametrization,

$$\frac{dx}{dt} = -\sin t, \quad \frac{dy}{dt} = -\sin t,$$

so that

$$\begin{aligned}
 \int_C x^2 y ds &= \int_0^{\pi/2} \cos^2 t \cos t \sqrt{(-\sin t)^2 + (-\sin t)^2} dt = \int_0^{\pi/2} \sin t \cos^3 t \cdot \sqrt{2} dt \\
 &= \sqrt{2} \left[-\frac{1}{4} \cos^4 t \right]_0^{\pi/2} = \boxed{\frac{\sqrt{2}}{4}}.
 \end{aligned}$$

10. With the given parametrization,

$$\frac{dx}{dt} = 1, \quad \frac{dy}{dt} = 3,$$

so that

$$\int_C (y - x^2) ds = \int_0^1 (3t - t^2) \cdot \sqrt{1^2 + 3^2} dt = \sqrt{10} \left[\frac{3}{2}t^2 - \frac{1}{3}t^3 \right]_0^1 = \boxed{\frac{7\sqrt{10}}{6}}.$$

11. With the given parametrization,

$$\frac{dx}{dt} = 2t, \quad \frac{dy}{dt} = 4,$$

so that

$$\int_C xy \, ds = \int_0^2 t^2 \cdot 4t \sqrt{(2t)^2 + 4^2} \, dt = \int_0^2 4t^3 \sqrt{4t^2 + 16} \, dt.$$

Now make the substitution $u = 4t^2 + 16$, so that $du = 8t \, dt$. Then

$$4t^3 \, dt = \frac{1}{2} t^2 \cdot 8t \, dt = \frac{1}{2} \cdot \frac{u - 16}{4} \, du = \frac{u - 16}{8} \, du.$$

Further $t = 0$ corresponds to $u = 16$ and $t = 2$ to $u = 32$, so we get

$$\begin{aligned} \int_{16}^{32} \frac{u - 16}{8} \cdot u^{1/2} \, du &= \frac{1}{8} \int_{16}^{32} (u^{3/2} - 16u^{1/2}) \, du \\ &= \frac{1}{8} \left[\frac{2}{5} u^{5/2} - \frac{32}{3} u^{3/2} \right]_{16}^{32} \\ &= \frac{1}{8} \left(\left(\frac{2}{5} \cdot 4096\sqrt{2} - \frac{32}{3} \cdot 128\sqrt{2} \right) - \left(\frac{2}{5} \cdot 1024 - \frac{32}{3} \cdot 64 \right) \right) \\ &= \boxed{\frac{512}{15}(1 + \sqrt{2})}. \end{aligned}$$

12. With the given parametrization,

$$\frac{dx}{dt} = 1, \quad \frac{dy}{dt} = 6t,$$

so that

$$\int_C x \, ds = \int_0^1 t \sqrt{1^2 + (6t)^2} \, dt = \int_0^1 t \sqrt{36t^2 + 1} \, dt.$$

Now make the substitution $u = 36t^2 + 1$, so that $du = 72t \, dt$. Then $t = 0$ corresponds to $u = 1$, and $t = 1$ to $u = 37$, so we get

$$\int_1^{37} \frac{1}{72} u^{1/2} \, du = \frac{1}{72} \left[\frac{2}{3} u^{3/2} \right]_1^{37} = \boxed{\frac{1}{108}(37\sqrt{37} - 1)}.$$

13. With the given parametrization,

$$\frac{dx}{dt} = 1, \quad \frac{dy}{dt} = 1,$$

so that

$$\int_C \frac{y}{2x^2 - y^2} \, ds = \int_1^5 \frac{t}{2t^2 - t^2} \cdot \sqrt{1^2 + 1^2} \, dt = \sqrt{2} \int_1^5 \frac{1}{t} \, dt = \sqrt{2} [\ln t]_1^5 = \boxed{\sqrt{2} \ln 5}.$$

14. With the given parametrization,

$$\frac{dx}{dt} = 3, \quad \frac{dy}{dt} = 4,$$

so that

$$\int_C \frac{x^2}{x^3 + y^3} \, ds = \int_1^2 \frac{(3t)^2}{(3t)^3 + (4t)^3} \cdot \sqrt{3^2 + 4^2} \, dt = \frac{45}{91} \int_1^2 \frac{1}{t} \, dt = \frac{45}{91} [\ln t]_1^2 = \boxed{\frac{45}{91} \ln 2}.$$

15. Parametrize the curve by $x = 2t$, $y = \frac{1}{(2t)^3} = 4t^3$ for $0 \leq t \leq 1$ (we use this parametrization instead of the more usual $x = t$ to avoid fractions). Then

$$\frac{dx}{dt} = 2, \quad \frac{dy}{dt} = 12t^2,$$

so that

$$\int_C 2y \, ds = \int_0^1 8t^3 \sqrt{2^2 + (12t^2)^2} \, dt = \int_0^1 8t^3 \sqrt{144t^4 + 4} \, dt.$$

Now use the substitution $u = 144t^4 + 4$; then $du = 576t^3$, and $t = 0$ corresponds to $u = 4$ while $t = 1$ corresponds to $u = 148$, and we get

$$\frac{8}{576} \int_4^{148} u^{1/2} \, du = \frac{1}{72} \left[\frac{2}{3} u^{3/2} \right]_4^{148} = \frac{1}{108} (148^{3/2} - 4^{3/2}) = \boxed{\frac{2}{27} (37\sqrt{37} - 1)}.$$

16. Parametrize the curve by $y = t$, $x = 5t^3$ for $0 \leq t \leq 1$. Then

$$\frac{dx}{dt} = 15t^2, \quad \frac{dy}{dt} = 1,$$

so that

$$\int_C x \, ds = \int_0^1 5t^3 \sqrt{(15t^2)^2 + 1^2} \, dt = \int_0^1 5t^3 \sqrt{225t^4 + 1} \, dt.$$

Now use the substitution $u = 225t^4 + 1$; then $du = 900t^3$, and $t = 0$ corresponds to $u = 1$ while $t = 1$ corresponds to $u = 226$, and we get

$$\frac{5}{900} \int_1^{226} u^{1/2} \, du = \frac{1}{180} \left[\frac{2}{3} u^{3/2} \right]_1^{226} = \boxed{\frac{1}{270} (226\sqrt{226} - 1)}.$$

17. With the parametrization we get from $\mathbf{r}$, which is $x = \sin t$, $y = \cos t$, we have

$$\frac{dx}{dt} = \cos t, \quad \frac{dy}{dt} = -\sin t,$$

so that

$$\begin{aligned} \int_C (xy + 1) \, ds &= \int_0^\pi (\sin t \cos t + 1) \sqrt{(\cos t)^2 + (-\sin t)^2} \, dt = \int_0^\pi (\sin t \cos t + 1) \, dt \\ &= \left[\frac{1}{2} \sin^2 t + t \right]_0^\pi = \boxed{\pi}. \end{aligned}$$

18. With the parametrization we get from $\mathbf{r}$, which is $x = \cos t$, $y = \sin t$, we have

$$\frac{dx}{dt} = -\sin t, \quad \frac{dy}{dt} = \cos t,$$

so that

$$\begin{aligned} \int_C xy^2 \, ds &= \int_0^{\pi/2} \cos t \sin^2 t \sqrt{(-\sin t)^2 + (\cos t)^2} \, dt \\ &= \int_0^{\pi/2} \cos t \sin^2 t \sqrt{\sin^2 t + \cos^2 t} \, dt = \int_0^{\pi/2} \cos t \sin^2 t \, dt = \left[\frac{1}{3} \sin^3 t \right]_0^{\pi/2} = \boxed{\frac{1}{3}}. \end{aligned}$$

19. (a) With the given parametrization,

$$\frac{dx}{dt} = 1, \quad \frac{dy}{dt} = 1,$$

so that

$$\int_C (x + y^2) \, ds = \int_0^1 (t + t^2) \sqrt{1^2 + 1^2} \, dt = \sqrt{2} \left[\frac{1}{2} t^2 + \frac{1}{3} t^3 \right]_0^1 = \boxed{\frac{5}{6} \sqrt{2}}.$$

(b) With the given parametrization,

$$\frac{dx}{dt} = \cos t, \quad \frac{dy}{dt} = \cos t,$$

so that

$$\begin{aligned} \int_C (x + y^2) ds &= \int_0^{\pi/2} (\sin t + \sin^2 t) \sqrt{\cos^2 t + \cos^2 t} dt \\ &= \sqrt{2} \int_0^{\pi/2} (\sin t \cos t + \sin^2 t \cos t) dt \\ &= \sqrt{2} \left[\frac{1}{2} \sin^2 t + \frac{1}{3} \sin^3 t \right]_0^{\pi/2} \\ &= \boxed{\frac{5}{6} \sqrt{2}}. \end{aligned}$$

20. (a) With the given parametrization,

$$\frac{dx}{dt} = 1, \quad \frac{dy}{dt} = 3,$$

so that

$$\int_C (x + y) ds = \int_0^1 4t \sqrt{1^2 + 3^2} dt = 4\sqrt{10} \int_0^1 t dt = 4\sqrt{10} \left[\frac{1}{2} t^2 \right]_0^1 = \boxed{2\sqrt{10}}.$$

(b) With the given parametrization,

$$\frac{dx}{dt} = 2 \cos(2t), \quad \frac{dy}{dt} = 6 \cos(2t),$$

so that

$$\int_C (x + y) ds = \int_0^{\pi/2} 4 \sin(2t) \cdot \sqrt{(2 \cos(2t))^2 + (6 \cos(2t))^2} dt = 8\sqrt{10} \int_0^{\pi/2} \sin(2t) \cdot \sqrt{\cos^2(2t)} dt.$$

We must now be careful: for $0 \leq t \leq \frac{\pi}{4}$, $\cos(2t) \geq 0$, but for $\frac{\pi}{4} \leq t \leq \frac{\pi}{2}$, $\cos(2t) \leq 0$. So when we take the square root of $\cos^2(2t)$, we must split this into two integrals:

$$\begin{aligned} 8\sqrt{10} \int_0^{\pi/2} \sin(2t) \cdot \sqrt{\cos^2(2t)} dt &= 8\sqrt{10} \left(\int_0^{\pi/4} \sin(2t) \cos(2t) dt - \int_{\pi/4}^{\pi/2} \sin(2t) \cos(2t) dt \right) \\ &= 8\sqrt{10} \left(\left[\frac{1}{4} \sin^2(2t) \right]_0^{\pi/4} - \left[\frac{1}{4} \sin^2(2t) \right]_{\pi/4}^{\pi/2} \right) \\ &= 8\sqrt{10} \left(\frac{1}{4} - \left(-\frac{1}{4} \right) \right) = \boxed{4\sqrt{10}}. \end{aligned}$$

21. (a) With the given parametrization,

$$\frac{dx}{dt} = -1, \quad \frac{dy}{dt} = 1,$$

so that

$$\int_C (x + e^y) ds = \int_0^1 (1 - t + e^t) \sqrt{(-1)^2 + 1^2} dt = \sqrt{2} \left[t - \frac{1}{2} t^2 + e^t \right]_0^1 = \boxed{\sqrt{2} e - \frac{1}{2} \sqrt{2}}.$$

(b) With the given parametrization,

$$\frac{dx}{dt} = -\sin t, \quad \frac{dy}{dt} = \sin t,$$

so that

$$\begin{aligned} \int_C (x + e^y) ds &= \int_0^{\pi/2} (\cos t + e^{1-\cos t}) \sqrt{(-\sin t)^2 + (\sin t)^2} dt \\ &= \sqrt{2} \int_0^{\pi/2} (\sin t \cos t + \sin t \cdot e^{1-\cos t}) dt \\ &= \sqrt{2} \left[\frac{1}{2} \sin^2 t + e^{1-\cos t} \right]_0^{\pi/2} \\ &= \sqrt{2} \left(\left(\frac{1}{2} + e \right) - (0 + 1) \right) \\ &= \boxed{\sqrt{2}e - \frac{1}{2}\sqrt{2}}. \end{aligned}$$

22. (a) With the given parametrization,

$$\frac{dx}{dt} = 1, \quad \frac{dy}{dt} = 1,$$

so that

$$\int_C x e^{x^2} ds = \int_0^1 (t+1) e^{(t+1)^2} \sqrt{1^2 + 1^2} dt = \sqrt{2} \int_0^1 (t+1) e^{(t+1)^2} dt.$$

Now use the substitution $u = (t+1)^2$, so that $du = 2(t+1) dt$; then $t = 0$ corresponds to $u = 1$ while $t = 1$ corresponds to $u = 4$, and we get

$$\sqrt{2} \int_0^1 (t+1) e^{(t+1)^2} dt = \sqrt{2} \int_1^4 \frac{1}{2} e^u du = \frac{\sqrt{2}}{2} [e^u]_1^4 = \boxed{\frac{\sqrt{2}}{2}(e^4 - e)}.$$

(b) With the given parametrization,

$$\frac{dx}{dt} = \cos t, \quad \frac{dy}{dt} = \cos t,$$

so that

$$\int_C x e^{x^2} ds = \int_0^{\pi/2} (1 + \sin t) e^{(1+\sin t)^2} \sqrt{\cos^2 t + \cos^2 t} dt = \sqrt{2} \int_0^{\pi/2} (1 + \sin t) e^{(1+\sin t)^2} \sqrt{\cos^2 t} dt.$$

To evaluate this integral, use the substitution $u = (1 + \sin t)^2$, so that $du = 2(1 + \sin t) \cos t$; then $t = 0$ corresponds to $u = 1$ and $t = \frac{\pi}{2}$ to $u = 4$. So the integral becomes

$$\sqrt{2} \int_1^4 \frac{1}{2} e^u du = \frac{\sqrt{2}}{2} [e^u]_1^4 = \boxed{\frac{\sqrt{2}}{2}(e^4 - e)}.$$

23. Since $g(x) = y = 3 - x$, we have $g'(x) = -1$, so that

$$\begin{aligned} \int_C f(x, y) dx &= \int_0^3 (2x + (3-x)^2) dx = \left[x^2 - \frac{1}{3}(3-x)^3 \right]_0^3 = \boxed{18} \\ \int_C f(x, y) dy &= \int_0^3 (2x + (3-x)^2) g'(x) dx = - \int_0^3 (2x + (3-x)^2) dx = - \left[x^2 - \frac{1}{3}(3-x)^3 \right]_0^3 = \boxed{-18}. \end{aligned}$$

24. $2x - y = 1$ is the same as $y = 2x - 1$, so with $g(x) = 2x - 1$ we have $g'(x) = 2$. Then

$$\begin{aligned}\int_C f(x, y) dx &= \int_0^1 f(x, y) dx = \int_0^1 x e^{2x-1} dx \\ \int_C f(x, y) dy &= \int_0^1 f(x, y) g'(x) dx = 2 \int_0^1 x e^{2x-1} dx.\end{aligned}$$

To perform this integration, use integration by parts with $u = x$, $dv = e^{2x-1} dx$, so that $du = dx$ and $v = \frac{1}{2}e^{2x-1}$. Then

$$\begin{aligned}\int_0^1 x e^{2x-1} dx &= \left[\frac{1}{2} x e^{2x-1} \right]_0^1 - \frac{1}{2} \int_0^1 e^{2x-1} dx \\ &= \left(\frac{1}{2} e - 0 \right) - \frac{1}{2} \left[\frac{1}{2} e^{2x-1} \right]_0^1 \\ &= \frac{1}{2} e - \frac{1}{4} (e - e^{-1}) \\ &= \frac{1}{4} \left(e + \frac{1}{e} \right)\end{aligned}$$

Then we get

$$\begin{aligned}\int_C f(x, y) dx &= \int_0^1 x e^{2x-1} dx = \boxed{\frac{1}{4} \left(e + \frac{1}{e} \right)} \\ \int_C f(x, y) dy &= 2 \int_0^1 x e^{2x-1} dx = 2 \left(\frac{1}{4} \left(e + \frac{1}{e} \right) \right) = \boxed{\frac{1}{2} \left(e + \frac{1}{e} \right)}.\end{aligned}$$

25. Solve for y to get $g(x) = y = \frac{1}{2} \ln x$, which is valid since the range of x we are considering is from 1 to e^2 , where $\ln x$ is defined. Then $g'(x) = \frac{1}{2x}$, and

$$\begin{aligned}\int_C f(x, y) dx &= \int_1^{e^2} \left(x e^{\frac{1}{2} \ln x} \right) dx = \int_1^{e^2} x^{3/2} dx = \left[\frac{2}{5} x^{5/2} \right]_1^{e^2} = \boxed{\frac{2}{5} (e^5 - 1)} \\ \int_C f(x, y) dy &= \int_1^{e^2} f(x, y) g'(x) dx = \int_1^{e^2} \left(x e^{\frac{1}{2} \ln x} \right) \cdot \frac{1}{2x} dx = \frac{1}{2} \int_1^{e^2} x^{1/2} dx \\ &= \frac{1}{2} \left[\frac{2}{3} x^{3/2} \right]_1^{e^2} = \boxed{\frac{1}{3} (e^3 - 1)}.\end{aligned}$$

26. Parametrize the curve by $y(t) = t$, $x(t) = 2t^2$ for $0 \leq t \leq \sqrt{\pi}$. Then $y'(t) = 1$ and $x'(t) = 4t$, so that

$$\begin{aligned}\int_C f(x, y) dx &= \int_0^{\sqrt{\pi}} f(x(t), y(t)) x'(t) dt = \int_0^{\sqrt{\pi}} (2t^2)^2 t \cdot 4t dt = 16 \int_0^{\sqrt{\pi}} t^6 dt = 16 \left[\frac{1}{7} t^7 \right]_0^{\sqrt{\pi}} \\ &= \boxed{\frac{16}{7} \pi^3 \sqrt{\pi}} \\ \int_C f(x, y) dy &= \int_0^{\sqrt{\pi}} f(x(t), y(t)) y'(t) dt = \int_0^{\sqrt{\pi}} (2t^2)^2 t \cdot 1 dt = 4 \int_0^{\sqrt{\pi}} t^5 dt = 4 \left[\frac{1}{6} t^6 \right]_0^{\sqrt{\pi}} = \boxed{\frac{2}{3} \pi^3}.\end{aligned}$$

27. (a) Using the given parametrization, $x'(t) = -\sin t$ and $y'(t) = \cos t$, so that

$$\begin{aligned}\int_C (x^2 y dx + xy dy) &= \int_C x^2 y dx + \int_C xy dy = \int_0^{\pi/2} x(t)^2 y(t) x'(t) dt + \int_0^{\pi/2} x(t) y(t) y'(t) dt \\ &= \int_0^{\pi/2} \cos^2 t \cdot \sin t \cdot (-\sin t) dt + \int_0^{\pi/2} \cos t \sin t \cdot \cos t dt \\ &= -\int_0^{\pi/2} \sin^2 t \cos^2 t dt + \int_0^{\pi/2} \cos^2 t \sin t dt.\end{aligned}$$

For the first integral, use the formulas for $\sin(2t)$ and $\cos(4t)$:

$$\sin^2 t \cos^2 t = (\sin t \cos t)^2 = \left(\frac{1}{2} \sin(2t)\right)^2 = \frac{1}{4} \sin^2(2t) = \frac{1}{4} \left(\frac{1}{2} - \frac{1}{2} \cos(4t)\right) = \frac{1}{8} - \frac{1}{8} \cos(4t).$$

So the integral becomes

$$\begin{aligned}\int_C (x^2 y dx + xy dy) &= -\int_0^{\pi/2} \left(\frac{1}{8} - \frac{1}{8} \cos(4t)\right) dt + \int_0^{\pi/2} \cos^2 t \sin t dt \\ &= -\left[\frac{1}{8}t - \frac{1}{32} \sin(4t)\right]_0^{\pi/2} + \left[-\frac{1}{3} \cos^3 t\right]_0^{\pi/2} \\ &= -\left(\left(\frac{1}{8} \cdot \frac{\pi}{2} - \frac{1}{32} \sin(2\pi)\right) - (0 - 0)\right) + \left(0 + \frac{1}{3} \cos 0\right) \\ &= \boxed{\frac{1}{3} - \frac{\pi}{16}}.\end{aligned}$$

- (b) Set $y(t) = t$ and $x(t) = \sqrt{1-t^2}$; then $0 \leq t \leq 1$. So $y'(t) = 1$ and $x'(t) = -\frac{t}{\sqrt{1-t^2}}$, so that

$$\begin{aligned}\int_C (x^2 y dx + xy dy) &= \int_C x^2 y dx + \int_C xy dy = \int_0^1 x(t)^2 y(t) x'(t) dt + \int_0^1 x(t) y(t) y'(t) dt \\ &= \int_0^1 \left(\sqrt{1-t^2}\right)^2 \cdot t \cdot \frac{-t}{\sqrt{1-t^2}} dt + \int_0^1 \sqrt{1-t^2} \cdot t \cdot 1 dt \\ &= -\int_0^1 t^2 \sqrt{1-t^2} dt + \int_0^1 t \sqrt{1-t^2} dt.\end{aligned}$$

For the first integral, use the trigonometric substitution $t = \sin \theta$, so that $dt = \cos \theta d\theta$, and $\sqrt{1-t^2} = \cos \theta$. We are justified in using $\cos \theta$ rather than $-\cos \theta$ as the range of integration is from $t = 0$ to $t = 1$, which corresponds to $\theta = 0$ to $\theta = \frac{\pi}{2}$, and $\cos \theta$ is nonnegative there. For the second integral, use the substitution $u = 1 - t^2$, so that $du = -2t dt$; then $t = 0$ corresponds to $u = 1$, and $t = 1$ to $u = 0$. So we get

$$\begin{aligned}\int_C (x^2 y dx + xy dy) &= -\int_0^1 t^2 \sqrt{1-t^2} dt + \int_0^1 t \sqrt{1-t^2} dt \\ &= -\int_0^{\pi/2} \sin^2 \theta \sqrt{1-\sin^2 \theta} \cdot \cos \theta d\theta - \frac{1}{2} \int_1^0 \sqrt{u} du \\ &= -\int_0^{\pi/2} \sin^2 \theta \cos^2 \theta d\theta + \frac{1}{2} \int_0^1 \sqrt{u} du.\end{aligned}$$

We evaluated the first integral in part (a); use that value to continue:

$$\int_C (x^2 y dx + xy dy) = -\int_0^{\pi/2} \sin^2 \theta \cos^2 \theta d\theta + \frac{1}{2} \int_0^1 \sqrt{u} du = -\frac{\pi}{16} + \frac{1}{2} \left[\frac{2}{3} u^{3/2}\right]_0^1 = \boxed{\frac{1}{3} - \frac{\pi}{16}}.$$

28. (a) Using the given parametrization, $x'(t) = -3 \sin t$ and $y'(t) = 3 \cos t$, so that

$$\begin{aligned}\int_C (xy \, dx + xy^2 \, dy) &= \int_C xy \, dx + \int_C xy^2 \, dy = \int_0^\pi x(t)y(t)x'(t) \, dt + \int_0^\pi x(t)y(t)^2 y'(t) \, dt \\ &= \int_0^\pi 3 \cos t \cdot 3 \sin t \cdot (-3 \sin t) \, dt + \int_0^\pi 3 \cos t \cdot (3 \sin t)^2 \cdot 3 \cos t \, dt \\ &= -27 \int_0^\pi \sin^2 t \cos t \, dt + 81 \int_0^\pi \sin^2 t \cos^2 t \, dt.\end{aligned}$$

For the second integral, use the formulas for $\sin(2t)$ and $\cos(4t)$:

$$\sin^2 t \cos^2 t = (\sin t \cos t)^2 = \left(\frac{1}{2} \sin(2t)\right)^2 = \frac{1}{4} \sin^2(2t) = \frac{1}{4} \left(\frac{1}{2} - \frac{1}{2} \cos(4t)\right) = \frac{1}{8} - \frac{1}{8} \cos(4t).$$

So the integral becomes

$$\begin{aligned}\int_C (xy \, dx + xy^2 \, dy) &= -27 \int_0^\pi \sin^2 t \cos t \, dt + 81 \int_0^\pi \sin^2 t \cos^2 t \, dt \\ &= -27 \left[\frac{1}{3} \sin^3 t \right]_0^\pi + 81 \int_0^\pi \left(\frac{1}{8} - \frac{1}{8} \cos(4t) \right) dt \\ &= -27(0 - 0) + 81 \left[\frac{1}{8} t - \frac{1}{32} \sin(4t) \right]_0^\pi \\ &= 81 \left(\frac{1}{8} \pi - 0 \right) = \boxed{\frac{81}{8} \pi}.\end{aligned}$$

- (b) Set $g(x) = y = \sqrt{9 - x^2}$; then $g'(x) = -\frac{x}{\sqrt{9 - x^2}}$, so we get

$$\begin{aligned}\int_C (xy \, dx + xy^2 \, dy) &= \int_C xy \, dx + \int_C xy^2 \, dy \\ &= \int_{-3}^3 x \sqrt{9 - x^2} \, dx + \int_{-3}^3 x (\sqrt{9 - x^2})^2 \left(-\frac{x}{\sqrt{9 - x^2}} \right) dx \\ &= \int_{-3}^3 x \sqrt{9 - x^2} \, dx - \int_{-3}^3 x^2 \sqrt{9 - x^2} \, dx\end{aligned}$$

For the first integral, use the substitution $u = 9 - x^2$, so that $du = -2x \, dx$; then $x = -3$ corresponds to $u = 0$ as does $x = 3$. For the second integral, use the trigonometric substitution $x = 3 \cos \theta$; then $du = -3 \sin \theta \, d\theta$ and $\sqrt{9 - x^2} = \sqrt{9 - 9 \cos^2 \theta} = 3 \sin \theta$. We are justified in using this square root since $x = -3$ corresponds to $\theta = \pi$ and $x = 3$ to $\theta = 0$; $\sin \theta$ is nonnegative in this range. So the integral becomes

$$\begin{aligned}\int_C (xy \, dx + xy^2 \, dy) &= \int_{-3}^3 x \sqrt{9 - x^2} \, dx - \int_{-3}^3 x^2 \sqrt{9 - x^2} \, dx \\ &= -\frac{1}{2} \int_0^0 u^{1/2} \, du - \int_\pi^0 (3 \cos \theta)^2 \cdot 3 \sin \theta \cdot (-3 \sin \theta) \, d\theta \\ &= 0 + 81 \int_\pi^0 \sin^2 \theta \cos^2 \theta \, d\theta.\end{aligned}$$

We evaluated this integral in part (a); using that value, we get

$$\int_C (xy \, dx + xy^2 \, dy) = \boxed{-\frac{81}{8} \pi}.$$

Note that this value is the negative of the value in part (a). If we had integrated in the opposite direction, from $x = 3$ to $x = -3$, we would get the same value; this direction corresponds to x ranging from 0 to π in the first parametrization.

29. (a) Set $g(x) = y = 3x$; then $g'(x) = 3$, so we get

$$\begin{aligned}
 \int_C (y^2 dx + (xy - x^2) dy) &= \int_C y^2 dx + \int_C (xy - x^2)g'(x) dx \\
 &= \int_0^1 (3x)^2 dx + \int_0^1 (x \cdot 3x - x^2) \cdot 3 dx \\
 &= 9 \int_0^1 x^2 dx + 6 \int_0^1 x^2 dx \\
 &= 15 \int_0^1 x^2 dx \\
 &= 15 \left[\frac{1}{3} x^3 \right]_0^1 = \boxed{5}.
 \end{aligned}$$

(b) Solve for y to get $g(x) = y = 3\sqrt{x}$. Then $g'(x) = \frac{3}{2\sqrt{x}}$, so we get

$$\begin{aligned}
 \int_C (y^2 dx + (xy - x^2) dy) &= \int_C y^2 dx + \int_C (xy - x^2)g'(x) dx \\
 &= \int_0^1 9x dx + \int_0^1 (3x\sqrt{x} - x^2) \frac{3}{2\sqrt{x}} dx \\
 &= \int_0^1 9x dx + \int_0^1 \left(\frac{9}{2}x - \frac{3}{2}x^{3/2} \right) dx \\
 &= \left[\frac{9}{2}x^2 + \frac{9}{4}x^2 - \frac{3}{5}x^{5/2} \right]_0^1 \\
 &= \boxed{\frac{123}{20} = 6.15}.
 \end{aligned}$$

30. (a) Set $g(x) = y = x^2$; then $g'(x) = 2x$, so we get

$$\begin{aligned}
 \int_C ((x^2 + y^2) dx + 3x^2 y dy) &= \int_C (x^2 + y^2) dx + \int_C 3x^2 y g'(x) dx \\
 &= \int_{-2}^2 (x^2 + x^4) dx + \int_{-2}^2 3x^2 \cdot x^2 \cdot 2x dx \\
 &= \int_{-2}^2 (x^2 + x^4) dx + \int_{-2}^2 6x^5 dx \\
 &= \left[\frac{1}{3}x^3 + \frac{1}{5}x^5 \right]_{-2}^2 + [x^6]_{-2}^2 \\
 &= \left(\frac{1}{3}2^3 + \frac{1}{5}2^5 \right) - \left(\frac{1}{3}(-2)^3 + \frac{1}{5}(-2)^5 \right) + 0 \\
 &= \boxed{\frac{272}{15}}.
 \end{aligned}$$

(b) Set $g(x) = y = 4$; then $g'(x) = 0$, so we get

$$\begin{aligned}
 \int_C ((x^2 + y^2) dx + 3x^2 y dy) &= \int_C (x^2 + y^2) dx + \int_C 3x^2 y g'(x) dx \\
 &= \int_{-2}^2 (x^2 + 16) dx + \int_{-2}^2 3x^2 \cdot 4 \cdot 0 dx \\
 &= \int_{-2}^2 (x^2 + 16) dx \\
 &= \left[\frac{1}{3}x^3 + 16x \right]_{-2}^2 \\
 &= \boxed{\frac{208}{3}}.
 \end{aligned}$$

31. Let $g(x) = y = x^2$; then $g'(x) = 2x$, so that

$$\begin{aligned}
 \int_C ((x + 2y) dx + (2x + y) dy) &= \int_C (x + 2y) dx + \int_C (2x + y) g'(x) dx \\
 &= \int_0^1 (x + 2x^2) dx + \int_0^1 (2x + x^2) \cdot 2x dx \\
 &= \int_0^1 (x + 2x^2) dx + \int_0^1 (4x^2 + 2x^3) dx \\
 &= \left[\frac{1}{2}x^2 + \frac{2}{3}x^3 \right]_0^1 + \left[\frac{4}{3}x^3 + \frac{1}{2}x^4 \right]_0^1 \\
 &= \boxed{3}.
 \end{aligned}$$

32. Let $g(x) = y = x^3$; then $g'(x) = 3x^2$, so that

$$\begin{aligned}
 \int_C ((x + 2y) dx + (2x + y) dy) &= \int_C (x + 2y) dx + \int_C (2x + y) g'(x) dx \\
 &= \int_0^1 (x + 2x^3) dx + \int_0^1 (2x + x^3) \cdot 3x^2 dx \\
 &= \int_0^1 (x + 2x^3) dx + \int_0^1 (6x^3 + 3x^5) dx \\
 &= \left[\frac{1}{2}x^2 + \frac{1}{2}x^4 \right]_0^1 + \left[\frac{3}{2}x^4 + \frac{1}{2}x^6 \right]_0^1 \\
 &= \boxed{3}.
 \end{aligned}$$

33. We have $x'(t) = -\sin t$ and $y'(t) = \cos t$, so that

$$\begin{aligned}
 \int_C ((x+2y) dx + (2x+y) dy) &= \int_C (x+2y) dx + \int_C (2x+y) dy \\
 &= \int_0^{\pi/2} (x(t) + 2y(t))x'(t) dt + \int_0^{\pi/2} (2x(t) + y(t))y'(t) dt \\
 &= \int_0^{\pi/2} (\cos t + 2\sin t)(-\sin t) dt + \int_0^{\pi/2} (2\cos t + \sin t)\cos t dt \\
 &= -\int_0^{\pi/2} (\sin t \cos t + 2\sin^2 t) dt + \int_0^{\pi/2} (2\cos^2 t + \sin t \cos t) dt \\
 &= \int_0^{\pi/2} (2\cos^2 t - 2\sin^2 t) dt \\
 &= \int_0^{\pi/2} 2\cos(2t) dt \\
 &= [\sin(2t)]_0^{\pi/2} = \boxed{0}.
 \end{aligned}$$

34. We have $x'(t) = -1$ and $y'(t) = 1$, so that

$$\begin{aligned}
 \int_C ((x+2y) dx + (2x+y) dy) &= \int_C (x+2y) dx + \int_C (2x+y) dy \\
 &= \int_0^1 (x(t) + 2y(t))x'(t) dt + \int_0^1 (2x(t) + y(t))y'(t) dt \\
 &= \int_0^1 (1-t+2t)(-1) dt + \int_0^1 (2(1-t) + t) \cdot 1 dt \\
 &= \int_0^1 (-t-1) dt + \int_0^1 (-t+2) dt \\
 &= \int_0^1 (1-2t) dt \\
 &= [t-t^2]_0^1 = \boxed{0}.
 \end{aligned}$$

35. The first curve may be parametrized by $x = t$, $y = 2 - t^2$, for $0 \leq t \leq 1$. Then $x'(t) = 1$, $y'(t) = -2t$. The second curve may be parametrized by $x = t$, $y = t$, for t from 1 to 0. Then $x'(t) = y'(t) = 1$. So the integral is

$$\int_C x ds = \int_0^1 t\sqrt{1^2 + (-2t)^2} dt + \int_1^0 t\sqrt{1^2 + 1^2} dt = \int_0^1 t\sqrt{4t^2 + 1} dt + \int_1^0 t\sqrt{2} dt.$$

For the first integral, use the substitution $u = 4t^2 + 1$, so that $du = 8t dt$; then $t = 0$ corresponds to $u = 1$ and $t = 1$ to $u = 5$, and we get

$$\begin{aligned}
 \int_C x ds &= \int_0^1 t\sqrt{4t^2 + 1} dt + \int_1^0 t\sqrt{2} dt \\
 &= \frac{1}{8} \int_1^5 u^{1/2} du + \left[\frac{\sqrt{2}}{2} t^2 \right]_1^0 \\
 &= \frac{1}{8} \left[\frac{2}{3} u^{3/2} \right]_1^5 - \frac{\sqrt{2}}{2} \\
 &= \boxed{\frac{5}{12}\sqrt{5} - \frac{1}{12} - \frac{1}{2}\sqrt{2}}.
 \end{aligned}$$

36. The first curve may be parametrized by $x = t$, $y = t^2$, for $0 \leq t \leq 1$. Then $x'(t) = 1$, $y'(t) = 2t$. The second curve may be parametrized by $x = t$, $y = 2 - t$, for $1 \leq t \leq 2$. Then $x'(t) = 1$ and $y'(t) = -1$. So the integral is

$$\int_C x \, ds = \int_0^1 t \sqrt{1^2 + (2t)^2} \, dt + \int_1^2 t \sqrt{1^2 + (-1)^2} \, dt = \int_0^1 t \sqrt{4t^2 + 1} \, dt + \int_1^2 t \sqrt{2} \, dt.$$

The first integral can be evaluated as in Problem 35 to get $\frac{1}{12}(5\sqrt{5} - 1)$, so we get

$$\int_C x \, ds = \frac{1}{12}(5\sqrt{5} - 1) + \left[\frac{\sqrt{2}}{2} t^2 \right]_1^2 = \boxed{\frac{1}{12}(5\sqrt{5} - 1) + \frac{3}{2}\sqrt{2}}.$$

37. The three curves, starting from $(1, 0)$, can be parametrized by:

$$\begin{aligned} x = t, \, y = t - 1, \, 1 \leq t \leq 2, \quad x'(t) = 1, \, y'(t) = 1 \\ x = t, \, y = 3 - t, \, 2 \leq t \leq 3, \quad x'(t) = 1, \, y'(t) = -1 \\ x = t, \, y = 0, \, t \text{ from } 3 \text{ to } 1, \quad x'(t) = 1, \, y'(t) = 0. \end{aligned}$$

So the integral is

$$\begin{aligned} \int_C x \, ds &= \int_1^2 t \sqrt{1^2 + 1^2} \, dt + \int_2^3 t \sqrt{1^2 + (-1)^2} \, dt + \int_3^1 t \sqrt{1^2 + 0^2} \, dt \\ &= \int_1^2 t \sqrt{2} \, dt + \int_2^3 t \sqrt{2} \, dt + \int_3^1 t \, dt \\ &= \sqrt{2} \int_1^2 t \, dt + \int_3^1 t \, dt \\ &= \sqrt{2} \left[\frac{1}{2} t^2 \right]_1^2 + \left[\frac{1}{2} t^2 \right]_3^1 \\ &= \sqrt{2} \left(\frac{9}{2} - \frac{1}{2} \right) + \left(\frac{1}{2} - \frac{9}{2} \right) \\ &= \boxed{4\sqrt{2} - 4}. \end{aligned}$$

38. The three curves, starting from $(0, 0)$, can be parametrized by:

$$\begin{aligned} y = t, \, x = t^2, \, 0 \leq t \leq 1, \quad y'(t) = 1, \, x'(t) = 2t \\ x = t, \, y = 2 - t, \, 1 \leq t \leq 3, \quad x'(t) = 1, \, y'(t) = -1 \\ x = t, \, y = -\frac{1}{3}t, \, t \text{ from } 3 \text{ to } 0, \quad x'(t) = 1, \, y'(t) = -\frac{1}{3}. \end{aligned}$$

So the integral is

$$\begin{aligned} \int_C x \, ds &= \int_0^1 t^2 \sqrt{(2t)^2 + 1^2} \, dt + \int_1^3 t \sqrt{1^2 + (-1)^2} \, dt + \int_3^0 t \sqrt{1^2 + \left(-\frac{1}{3}\right)^2} \, dt \\ &= \int_0^1 t^2 \sqrt{4t^2 + 1} \, dt + \int_1^3 t \sqrt{2} \, dt + \int_3^0 t \frac{\sqrt{10}}{3} \, dt. \end{aligned}$$

For the first integral, we use the trigonometric substitution $t = \frac{1}{2} \tan \theta$; then $dt = \frac{1}{2} \sec^2 \theta$, and $\sqrt{4t^2 + 1} = \sqrt{\tan^2 \theta + 1} = \sec \theta$. We are justified in using the positive square root, not the negative one, since $t = 0$ corresponds to $\theta = 0$ and $t = 1$ to $\theta = \tan^{-1} 2$, and $\sec \theta$ is positive on that range. So

we get

$$\begin{aligned}
 \int_C x \, ds &= \int_0^1 t^2 \sqrt{4t^2 + 1} \, dt + \int_1^3 t\sqrt{2} \, dt + \int_3^0 t \frac{\sqrt{10}}{3} \, dt \\
 &= \int_0^{\tan^{-1} 2} \left(\frac{1}{2} \tan \theta \right)^2 \cdot \sec \theta \cdot \frac{1}{2} \sec^2 \theta \, d\theta + \sqrt{2} \left[\frac{1}{2} t^2 \right]_1^3 + \frac{\sqrt{10}}{3} \left[\frac{1}{2} t^2 \right]_3^0 \\
 &= \frac{1}{8} \int_0^{\tan^{-1} 2} \tan^2 \theta \sec^3 \theta \, d\theta + 4\sqrt{2} - \frac{3}{2}\sqrt{10}.
 \end{aligned}$$

To evaluate the remaining integral, we use the substitution $\tan^2 \theta = \sec^2 \theta - 1$ and then the reduction formula from Example 8 in Section 7.1:

$$\begin{aligned}
 \int_C x \, ds &= \frac{1}{8} \int_0^{\tan^{-1} 2} \tan^2 \theta \sec^3 \theta \, d\theta + 4\sqrt{2} - \frac{3}{2}\sqrt{10} \\
 &= \frac{1}{8} \int_0^{\tan^{-1} 2} (\sec^2 \theta - 1) \sec^3 \theta \, d\theta + 4\sqrt{2} - \frac{3}{2}\sqrt{10} \\
 &= \frac{1}{8} \left(\int_0^{\tan^{-1} 2} \sec^5 \theta \, d\theta - \int_0^{\tan^{-1} 2} \sec^3 \theta \, d\theta \right) + 4\sqrt{2} - \frac{3}{2}\sqrt{10} \\
 &= \frac{1}{8} \left(\left[\frac{\sec^3 \theta \tan \theta}{4} \right]_0^{\tan^{-1} 2} + \frac{3}{4} \int_0^{\tan^{-1} 2} \sec^3 \theta \, d\theta - \int_0^{\tan^{-1} 2} \sec^3 \theta \, d\theta \right) + 4\sqrt{2} - \frac{3}{2}\sqrt{10} \\
 &= \frac{1}{8} \left(\frac{5\sqrt{5} \cdot 2}{4} - \frac{1}{4} \int_0^{\tan^{-1} 2} \sec^3 \theta \, d\theta \right) + 4\sqrt{2} - \frac{3}{2}\sqrt{10} \\
 &= \frac{1}{8} \left(\frac{5\sqrt{5}}{2} - \frac{1}{4} \left(\left[\frac{\sec \theta \tan \theta}{2} \right]_0^{\tan^{-1} 2} + \frac{1}{2} \int_0^{\tan^{-1} 2} \sec \theta \, d\theta \right) \right) + 4\sqrt{2} - \frac{3}{2}\sqrt{10} \\
 &= \frac{5\sqrt{5}}{16} + 4\sqrt{2} - \frac{3}{2}\sqrt{10} - \frac{1}{32} \cdot \frac{\sqrt{5} \cdot 2}{2} - \frac{1}{64} [\ln |\sec \theta + \tan \theta|]_0^{\tan^{-1} 2} \\
 &= \frac{9\sqrt{5}}{32} + 4\sqrt{2} - \frac{3}{2}\sqrt{10} - \frac{1}{64} (\ln(2 + \sqrt{5}) - \ln 1) \\
 &= \boxed{\frac{9\sqrt{5}}{32} + 4\sqrt{2} - \frac{3}{2}\sqrt{10} - \frac{1}{64} \ln(2 + \sqrt{5})}.
 \end{aligned}$$

39. Parametrize the segments as follows:

$$\begin{aligned}
 C_1 : (0, 0) \text{ to } (1, 0) : \quad x(t) &= t, \quad y(t) = 0, \quad 0 \leq t \leq 1 \\
 C_2 : (1, 0) \text{ to } (1, 1) : \quad x(t) &= 1, \quad y(t) = t, \quad 0 \leq t \leq 1 \\
 C_3 : (1, 1) \text{ to } (0, 1) : \quad x(t) &= 1 - t, \quad y(t) = 1, \quad 0 \leq t \leq 1.
 \end{aligned}$$

Then

$$\begin{aligned}
& \int_C (x \cos y \, dx - y \sin x \, dy) \\
&= \int_{C_1} (x \cos y \, dx - y \sin x \, dy) + \int_{C_2} (x \cos y \, dx - y \sin x \, dy) + \int_{C_3} (x \cos y \, dx - y \sin x \, dy) \\
&= \int_0^1 t \cos 0 \cdot 1 \, dt - \int_0^1 0 \cdot \sin t \cdot 0 \, dt + \int_0^1 1 \cos t \cdot 0 \, dt - \int_0^1 t \sin 1 \cdot 1 \, dt \\
&\quad + \int_0^1 (1-t) \cos 1 \cdot (-1) \, dt - \int_0^1 1 \cdot \sin(1-t) \cdot 0 \, dt \\
&= \int_0^1 t \, dt - 0 + 0 - \int_0^1 t \sin 1 \, dt - \int_0^1 (1-t) \cos 1 \, dt - 0 \\
&= \int_0^1 t \, dt - \int_0^1 t \sin 1 \, dt - \int_0^1 (1-t) \cos 1 \, dt \\
&= \left[\frac{1}{2} t^2 \right]_0^1 - \left[\frac{1}{2} t^2 \sin 1 \right]_0^1 - \left[-\frac{1}{2} (1-t)^2 \cos 1 \right]_0^1 \\
&= \boxed{\frac{1}{2} (1 - \sin 1 - \cos 1)}.
\end{aligned}$$

40. Parametrize the segments as follows:

$$\begin{aligned}
C_1 : (0, 0) \text{ to } (0, 1) : & \quad x(t) = 0, \, y(t) = t, \, 0 \leq t \leq 1 \\
C_2 : (0, 1) \text{ to } (1, 1) : & \quad x(t) = t, \, y(t) = 1, \, 0 \leq t \leq 1 \\
C_3 : (1, 1) \text{ to } (1, 0) : & \quad x(t) = 1, \, y(t) = 1 - t, \, 0 \leq t \leq 1.
\end{aligned}$$

Then

$$\begin{aligned}
& \int_C (x \sin y \, dx - y \cos x \, dy) \\
&= \int_{C_1} (x \sin y \, dx - y \cos x \, dy) + \int_{C_2} (x \sin y \, dx - y \cos x \, dy) + \int_{C_3} (x \sin y \, dx - y \cos x \, dy) \\
&= \int_0^1 0 \sin t \cdot 0 \, dt - \int_0^1 t \cos 0 \cdot 1 \, dt + \int_0^1 t \sin 1 \cdot 1 \, dt - \int_0^1 1 \cos t \cdot 0 \, dt \\
&\quad + \int_0^1 1 \sin(1-t) \cdot 0 \, dt - \int_0^1 (1-t) \cos 1 \cdot (-1) \, dt \\
&= 0 - \int_0^1 t \, dt + \int_0^1 t \sin 1 \, dt - 0 + 0 + \int_0^1 (1-t) \cos 1 \, dt \\
&= -\int_0^1 t \, dt + \int_0^1 t \sin 1 \, dt + \int_0^1 (1-t) \cos 1 \, dt \\
&= \left[-\frac{1}{2} t^2 \right]_0^1 + \left[\frac{1}{2} t^2 \sin 1 \right]_0^1 + \left[-\frac{1}{2} (1-t)^2 \cos 1 \right]_0^1 \\
&= \boxed{-\frac{1}{2} + \frac{1}{2} (\sin 1 + \cos 1)}.
\end{aligned}$$

41. Parametrize the segments as follows:

$$\begin{aligned}
C_1 : (0, 0, 0) \text{ to } (1, 0, 0) : & \quad x(t) = t, \, y(t) = 0, \, z(t) = 0, \, 0 \leq t \leq 1 \\
C_2 : (1, 0, 0) \text{ to } (1, 1, 0) : & \quad x(t) = 1, \, y(t) = t, \, z(t) = 0, \, 0 \leq t \leq 1 \\
C_3 : (1, 1, 0) \text{ to } (1, 1, 1) : & \quad x(t) = 1, \, y(t) = 1, \, z(t) = t, \, 0 \leq t \leq 1.
\end{aligned}$$

Then

$$\begin{aligned}
& \int_C (yz \, dx + xz \, dy + xy \, dz) \\
&= \int_{C_1} (yz \, dx + xz \, dy + xy \, dz) + \int_{C_2} (yz \, dx + xz \, dy + xy \, dz) + \int_{C_3} (yz \, dx + xz \, dy + xy \, dz) \\
&= \int_0^1 0 \cdot 0 \cdot 1 \, dt + \int_0^1 t \cdot 0 \cdot 0 \, dt + \int_0^1 t \cdot 0 \cdot 0 \, dt \\
&\quad + \int_0^1 t \cdot 0 \cdot 0 \, dt + \int_0^1 1 \cdot 0 \cdot 1 \, dt + \int_0^1 1 \cdot t \cdot 0 \, dt \\
&\quad + \int_0^1 1 \cdot t \cdot 0 \, dt + \int_0^1 1 \cdot t \cdot 0 \, dt + \int_0^1 1 \cdot 1 \cdot 1 \, dt \\
&= \int_0^1 1 \, dt \\
&= \boxed{1}.
\end{aligned}$$

42. Parametrize the segments as follows:

$$\begin{aligned}
C_1 : (0, 0, 0) \text{ to } (1, 0, 0) : \quad & x(t) = t, \, y(t) = 0, \, z(t) = 0, \, 0 \leq t \leq 1 \\
C_2 : (1, 0, 0) \text{ to } (1, 2, 0) : \quad & x(t) = 1, \, y(t) = t, \, z(t) = 0, \, 0 \leq t \leq 2 \\
C_3 : (1, 2, 0) \text{ to } (1, 2, 1) : \quad & x(t) = 1, \, y(t) = 2, \, z(t) = t, \, 0 \leq t \leq 1.
\end{aligned}$$

Then

$$\begin{aligned}
& \int_C (yz \, dx + (y + zx) \, dy + xz \, dz) \\
&= \int_{C_1} (yz \, dx + (y + zx) \, dy + xz \, dz) + \int_{C_2} (yz \, dx + (y + zx) \, dy + xz \, dz) \\
&\quad + \int_{C_3} (yz \, dx + (y + zx) \, dy + xz \, dz) \\
&= \int_0^1 (0 \cdot 0 \cdot 1 \, dt) + \int_0^1 (0 + 0 \cdot t) \cdot 0 \, dt + \int_0^1 t \cdot 0 \cdot 0 \, dt \\
&\quad + \int_0^2 t \cdot 0 \cdot 0 \, dt + \int_0^2 (t + 0 \cdot 1) \cdot 1 \, dt + \int_0^2 1 \cdot 0 \cdot 0 \, dt \\
&\quad + \int_0^1 2t \cdot 0 \, dt + \int_0^1 (2 + t \cdot 1) \cdot 0 \, dt + \int_0^1 1 \cdot t \cdot 1 \, dt \\
&= \int_0^2 t \, dt + \int_0^1 t \, dt \\
&= \left[\frac{1}{2} t^2 \right]_0^2 + \left[\frac{1}{2} t^2 \right]_0^1 = \boxed{\frac{5}{2}}.
\end{aligned}$$

43. Parametrize the line segment joining $(2, 0)$ and $(0, 4)$ by $x(t) = 2 - 2t$, $y(t) = 4t$ for $0 \leq t \leq 1$. Then $x'(t) = -2$ and $y'(t) = 4$, and we get

$$\begin{aligned}
 \int_C (y \, dx + (x - 16y) \, dy) &= \int_0^1 y(t)x'(t) \, dt + \int_0^1 (x(t) - 16y(t))y'(t) \, dt \\
 &= - \int_0^1 8t \, dt + \int_0^1 (2 - 2t - 16 \cdot 4t) \cdot 4 \, dt \\
 &= - \int_0^1 8t \, dt + 4 \int_0^1 (2 - 66t) \, dt \\
 &= - [4t^2]_0^1 + 4 [2t - 33t^2]_0^1 \\
 &= \boxed{-128}.
 \end{aligned}$$

44. With $g(x) = y = 4 - x^2$, we get $g'(x) = -2x$, so the integral is

$$\begin{aligned}
 \int_C (y \, dx + (x - 16y) \, dy) &= \int_2^0 (4 - x^2) \, dx + \int_2^0 (x - 16(4 - x^2)) \cdot (-2x) \, dx \\
 &= \int_2^0 (4 - x^2) \, dx + \int_2^0 (-32x^3 - 2x^2 + 128x) \, dx \\
 &= \left[4x - \frac{1}{3}x^3 \right]_2^0 + \left[-8x^4 - \frac{2}{3}x^3 + 64x^2 \right]_2^0 \\
 &= \boxed{-128}.
 \end{aligned}$$

45. Parametrize the line segments as follows:

$$\begin{aligned}
 C_1 : (2, 0) \text{ to } (2, 2) : \quad x(t) &= 2, \quad y(t) = 2t, \quad 0 \leq t \leq 1 \\
 C_2 : (2, 2) \text{ to } (0, 4) : \quad x(t) &= 2 - 2t, \quad y(t) = 2 + 2t, \quad 0 \leq t \leq 1.
 \end{aligned}$$

Then

$$\begin{aligned}
 \int_C (y \, dx + (x - 16y) \, dy) &= \int_{C_1} (y \, dx + (x - 16y) \, dy) + \int_{C_2} (y \, dx + (x - 16y) \, dy) \\
 &= \int_0^1 2t \cdot 0 \, dt + \int_0^1 (2 - 32t) \cdot 2 \, dt + \int_0^1 (2 + 2t) \cdot (-2) \, dt \\
 &\quad + \int_0^1 (2 - 2t - 16(2 + 2t)) \cdot 2 \, dt \\
 &= \int_0^1 (4 - 64t) \, dt - \int_0^1 (4 + 4t) \, dt + \int_0^1 (-60 - 68t) \, dt \\
 &= [4t - 32t^2]_0^1 - [4t + 2t^2]_0^1 + [-60t - 34t^2]_0^1 \\
 &= \boxed{-128}.
 \end{aligned}$$

46. Parametrize the line segment by $x(t) = 1 - t$, $y(t) = 3 + t$, $0 \leq t \leq 1$, so that $x'(t) = -1$ and $y'(t) = 1$. Then the integral is

$$\begin{aligned}
 \int_C (y \, dx + (x - 16y) \, dy) &= \int_{C_1} (y \, dx + (x - 16y) \, dy) + \int_{C_2} (y \, dx + (x - 16y) \, dy) \\
 &= \int_2^1 (4 - x^2) \, dx + \int_2^1 (x - 16(4 - x^2)) \cdot (-2x) \, dx + \int_0^1 (3 + t) \cdot (-1) \, dt \\
 &\quad + \int_0^1 ((1 - t) - 16(3 + t)) \cdot 1 \, dt \\
 &= \int_2^1 (4 - x^2) \, dx - \int_2^1 (32x^3 + 2x^2 - 128x) \, dx \\
 &\quad - \int_0^1 (3 + t) \, dt - \int_0^1 (47 + 17t) \, dt \\
 &= \left[4x - \frac{1}{3}x^3 \right]_2^1 - \left[8x^4 + \frac{2}{3}x^3 - 64x^2 \right]_2^1 - \left[3t + \frac{1}{2}t^2 \right]_0^1 - \left[47t + \frac{17}{2}t^2 \right]_0^1 \\
 &= -\frac{5}{3} - \frac{202}{3} - \frac{7}{2} - \frac{111}{2} = \boxed{-128}.
 \end{aligned}$$

47. With the parametrization for $\mathbf{r}$, we have $\mathbf{F} = (t + 2t^2)\mathbf{i} + (2t + t^2)\mathbf{j}$. Also $d\mathbf{r} = (\mathbf{i} + 2t\mathbf{j}) \, dt = (\mathbf{i} + 2t\mathbf{j}) \, dt$. Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 ((t + 2t^2)\mathbf{i} + (2t + t^2)\mathbf{j}) \cdot (\mathbf{i} + 2t\mathbf{j}) \, dt = \int_0^1 (t + 6t^2 + 2t^3) \, dt = \left[\frac{1}{2}t^2 + 2t^3 + \frac{1}{2}t^4 \right]_0^1 = \boxed{3}.$$

48. With the parametrization for $\mathbf{r}$, we have

$$\mathbf{F} = \cos^2 t \, \mathbf{i} + \cos t \sin t \, \mathbf{j}, \quad d\mathbf{r} = (-\sin t \, \mathbf{i} + \cos t \, \mathbf{j}) \, dt.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^\pi (\cos^2 t \, \mathbf{i} + \cos t \sin t \, \mathbf{j}) \cdot (-\sin t \, \mathbf{i} + \cos t \, \mathbf{j}) \, dt = \int_0^\pi (-\sin t \cos^2 t + \sin t \cos^2 t) \, dt = \boxed{0}.$$

49. With the parametrization for $\mathbf{r}$, we have

$$\mathbf{F} = e^t \cdot e^{-t} \mathbf{i} + e^{2t} t^2 \mathbf{j} + e^t e^{-t} t^2 \mathbf{k} = \mathbf{i} + t^2 e^{2t} \mathbf{j} + t^2 \mathbf{k}, \quad d\mathbf{r} = (e^t \mathbf{i} - e^{-t} \mathbf{j} + 2t \mathbf{k}) \, dt.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (\mathbf{i} + t^2 e^{2t} \mathbf{j} + t^2 \mathbf{k}) \cdot (e^t \mathbf{i} - e^{-t} \mathbf{j} + 2t \mathbf{k}) \, dt = \int_0^1 (e^t - t^2 e^t + 2t^3) \, dt.$$

From Example 7.1, we have $\int t^2 e^t \, dt = e^t(t^2 - 2t + 2) + C$, so the integral above becomes

$$\begin{aligned}
 \int_C \mathbf{F} \cdot d\mathbf{r} &= \left[e^t - e^t(t^2 - 2t + 2) + \frac{1}{2}t^4 \right]_0^1 \\
 &= \left(e - e(1 - 2 + 2) + \frac{1}{2} \right) - (1 - 1(0 - 0 + 2) + 0) = \boxed{\frac{3}{2}}.
 \end{aligned}$$

50. With the parametrization for $\mathbf{r}$, we have

$$\mathbf{F} = e^t \mathbf{i} + e^{4t} e^t \mathbf{j} + e^{2t} t \mathbf{k} = e^t \mathbf{i} + e^{5t} \mathbf{j} + t e^{2t} \mathbf{k}, \quad d\mathbf{r} = (2e^{2t} \mathbf{i} + e^t \mathbf{j} + \mathbf{k}) \, dt.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (e^t \mathbf{i} + e^{5t} \mathbf{j} + te^{2t} \mathbf{k}) \cdot (2e^{2t} \mathbf{i} + e^t \mathbf{j} + \mathbf{k}) dt = \int_0^1 (2e^{3t} + e^{6t} + te^{2t}) dt.$$

To integrate te^{2t} , use integration by parts, with $u = t$ and $dv = e^{2t} dt$, so that $du = dt$ and $v = \frac{1}{2}e^{2t}$. Then

$$\int te^{2t} dt = \frac{1}{2}te^{2t} - \frac{1}{2} \int e^{2t} dt = \frac{1}{2}te^{2t} - \frac{1}{4}e^{2t} + C,$$

so that the integral above becomes

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^1 (2e^{3t} + e^{6t} + te^{2t}) dt \\ &= \left[\frac{2}{3}e^{3t} + \frac{1}{6}e^{6t} + \frac{1}{2}te^{2t} - \frac{1}{4}e^{2t} \right]_0^1 \\ &= \boxed{\frac{2}{3}e^3 + \frac{1}{6}e^6 + \frac{1}{4}e^2 - \frac{7}{12}}. \end{aligned}$$

51. Parametrize $\mathbf{r}$ as $t\mathbf{i} + 0\mathbf{j} + 0\mathbf{k} = t\mathbf{i}$ for $0 \leq t \leq 1$. Then

$$\mathbf{F} = 0\mathbf{i} - 0\mathbf{j} + 0\mathbf{k} = \mathbf{0}, \quad d\mathbf{r} = \mathbf{i} dt.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \mathbf{0} \cdot \mathbf{i} dt = \boxed{0}.$$

52. Parametrize $\mathbf{r}$ as $\mathbf{i} + 2t\mathbf{j} + 0\mathbf{k} = \mathbf{i} + 2t\mathbf{j}$ for $0 \leq t \leq 1$. Then

$$\mathbf{F} = 2t\mathbf{i} - 2t\mathbf{j} + 0\mathbf{k}, \quad d\mathbf{r} = 2\mathbf{j} dt.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (2t\mathbf{i} - 2t\mathbf{j}) \cdot (2\mathbf{j}) dt = \int_0^1 (-4t) dt = [-2t^2]_0^1 = \boxed{-2}.$$

53. Parametrize $\mathbf{r}$ as $\mathbf{i} + 2\mathbf{j} + 3t\mathbf{k}$ for $0 \leq t \leq 1$. Then

$$\mathbf{F} = 2\mathbf{i} - 2\mathbf{j} + 3t\mathbf{k}, \quad d\mathbf{r} = 3\mathbf{k} dt.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (2\mathbf{i} - 2\mathbf{j} + 3t\mathbf{k}) \cdot (3\mathbf{k}) dt = \int_0^1 9t dt = \left[\frac{9}{2}t^2 \right]_0^1 = \boxed{\frac{9}{2}}.$$

54. Parametrize $\mathbf{r}$ as $t\mathbf{i} + 2t\mathbf{j} + 3t\mathbf{k}$ for $0 \leq t \leq 1$. Then

$$\mathbf{F} = t \cdot 2t\mathbf{i} - 2t\mathbf{j} + 3t\mathbf{k} = 2t^2\mathbf{i} - 2t\mathbf{j} + 3t\mathbf{k}, \quad d\mathbf{r} = \mathbf{i} + 2\mathbf{j} + 3\mathbf{k} dt.$$

Then

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^1 (2t^2\mathbf{i} - 2t\mathbf{j} + 3t\mathbf{k}) \cdot (\mathbf{i} + 2\mathbf{j} + 3\mathbf{k}) dt = \int_0^1 (2t^2 - 4t + 9t) dt \\ &= \int_0^1 (2t^2 + 5t) dt = \left[\frac{2}{3}t^3 + \frac{5}{2}t^2 \right]_0^1 = \boxed{\frac{19}{6}}. \end{aligned}$$

55. Along C , the differential of arc length is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{\cos^2 t + \sin^2 t} = 1,$$

so that

$$\begin{aligned} A = \int_C f(x, y) ds &= \int_0^{2\pi} (1 - \sin^2 t) dt = \int_0^{2\pi} \left(1 - \left(\frac{1}{2} - \frac{1}{2} \cos(2t)\right)\right) dt \\ &= \int_0^{2\pi} \left(\frac{1}{2} + \frac{1}{2} \cos(2t)\right) dt = \left[\frac{1}{2}t + \frac{1}{4} \sin(2t)\right]_0^{2\pi} = \boxed{\pi}. \end{aligned}$$

56. Along C , the differential of arc length is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt = \sqrt{\cos^2 t + \sin^2 t} dt = dt,$$

so that

$$\begin{aligned} A = \int_C f(x, y) ds &= \int_0^{2\pi} (1 - \cos^2 t) dt = \int_0^{2\pi} \left(1 - \left(\frac{1}{2} + \frac{1}{2} \cos(2t)\right)\right) dt \\ &= \int_0^{2\pi} \left(\frac{1}{2} - \frac{1}{2} \cos(2t)\right) dt = \left[\frac{1}{2}t - \frac{1}{4} \sin(2t)\right]_0^{2\pi} = \boxed{\pi}. \end{aligned}$$

57. Along C , the differential of arc length is

$$ds = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dt = \sqrt{1 + \left(\frac{1}{2}(1 - x^2)^{-1/2} \cdot (-2x)\right)^2} dt = \sqrt{1 + \frac{x^2}{1 - x^2}} dt = \frac{1}{\sqrt{1 - x^2}} dt,$$

so that

$$A = \int_C f(x, y) ds = \int_0^1 2x \sqrt{1 - x^2} \cdot \frac{1}{\sqrt{1 - x^2}} dx = \int_0^1 2x dx = [x^2]_0^1 = \boxed{1}.$$

58. Along C , the differential of arc length is

$$ds = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dt = \sqrt{1 + \left(\frac{1}{2}(1 - x^2)^{-1/2} \cdot (-2x)\right)^2} dt = \sqrt{1 + \frac{x^2}{1 - x^2}} = \frac{1}{\sqrt{1 - x^2}} dt,$$

so that

$$\begin{aligned} A = \int_C f(x, y) ds &= \int_0^1 \left(x + \sqrt{1 - x^2}\right) \cdot \frac{1}{\sqrt{1 - x^2}} dx = \int_0^1 \left(\frac{x}{\sqrt{1 - x^2}} + 1\right) dx \\ &= \int_0^1 \frac{x}{\sqrt{1 - x^2}} dx + \int_0^1 1 dx. \end{aligned}$$

For the first integral, make the substitution $u = 1 - x^2$, so that $du = -2x dx$; then $x = 0$ corresponds to $u = 1$, and $x = 1$ to $u = 0$, and we get

$$A = \int_0^1 \frac{x}{\sqrt{1 - x^2}} dx + \int_0^1 1 dx = -\frac{1}{2} \int_1^0 u^{-1/2} du + 1 = -\frac{1}{2} [2u^{1/2}]_1^0 + 1 = \boxed{2}.$$

Applications and Extensions

59. Using the given parametrization for C , we have

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} dt = \sqrt{a^2 \sin^2 t + a^2 \cos^2 t + b^2} dt = \sqrt{a^2 + b^2} dt.$$

Then

$$\int_C \frac{ds}{x^2 + y^2 + z^2} = \int_0^1 \frac{\sqrt{a^2 + b^2}}{a^2 \cos^2 t + a^2 \sin^2 t + b^2 t^2} dt = \sqrt{a^2 + b^2} \int_0^1 \frac{1}{a^2 + b^2 t^2} dt.$$

Now make the substitution $u = \frac{b}{a}t$, so that $du = \frac{b}{a} dt$. Then $t = 0$ corresponds to $u = 0$, and $t = 1$ to $u = \frac{b}{a}$, so we get

$$\begin{aligned} \int_C \frac{ds}{x^2 + y^2 + z^2} &= \sqrt{a^2 + b^2} \int_0^1 \frac{1}{a^2 + b^2 t^2} dt \\ &= \frac{a\sqrt{a^2 + b^2}}{b} \int_0^{b/a} \frac{1}{a^2 + a^2 u^2} du \\ &= \frac{\sqrt{a^2 + b^2}}{ab} \int_0^{b/a} \frac{1}{1 + u^2} du \\ &= \frac{\sqrt{a^2 + b^2}}{ab} [\tan^{-1} u]_0^{b/a} \\ &= \boxed{\frac{\sqrt{a^2 + b^2}}{ab} \tan^{-1} \frac{b}{a}}. \end{aligned}$$

60. Using the given parametrization for C , we have $x'(t) = a \cos t$ and $y'(t) = -b \sin t$. Then

$$\begin{aligned} \int_C (y^n dx + x^n dy) &= \int_C y^n dx + \int_C x^n dy \\ &= \int_0^1 y(t)^n x'(t) dt + \int_0^1 x(t)^n y'(t) dt \\ &= \int_0^{2\pi} b^n \cos^n t \cdot a \cos t dt - \int_0^{2\pi} a^n \sin^n t \cdot b \sin t dt \\ &= ab^n \int_0^{2\pi} \cos^{n+1} t dt - ba^n \int_0^{2\pi} \sin^{n+1} t dt. \end{aligned}$$

We will use numbers 90 and 91 in the table of integrals in the Endnotes to evaluate these integrals.

We have

$$\begin{aligned} \int_0^{2\pi} \cos^{n+1} t dt &= \left[\frac{1}{n+1} \cos^n t \sin t \right]_0^{2\pi} + \frac{n}{n+1} \int_0^{2\pi} \cos^{n-1} t dt \\ &= 0 + \frac{n}{n+1} \int_0^{2\pi} \cos^{n-1} t dt \\ &= \frac{n}{n+1} \left(\left[\frac{1}{n-1} \cos^{n-2} t \sin t \right]_0^{2\pi} + \frac{n-2}{n-1} \int_0^{2\pi} \cos^{n-3} t dt \right) \\ &= \frac{n(n-2)}{(n+1)(n-1)} \int_0^{2\pi} \cos^{n-3} t dt. \end{aligned}$$

Continuing this process, we will end up with either

$$\begin{aligned} \int_0^{2\pi} \cos^{n+1} t dt &= \frac{n(n-2) \cdots 2}{(n+1)(n-1) \cdots 3} \int_0^{2\pi} \cos t dt = \frac{n(n-2) \cdots 2}{(n+1)(n-1) \cdots 3} [\sin t]_0^{2\pi} = 0 \\ \int_0^{2\pi} \cos^{n+1} t dt &= \frac{n(n-2) \cdots 1}{(n+1)(n-1) \cdots 2} \int_0^{2\pi} 1 dt = 2\pi \frac{n(n-2) \cdots 1}{(n+1)(n-1) \cdots 2}, \end{aligned}$$

where the first equation applies if n is even and the second if n is odd.

Similarly, we have

$$\begin{aligned}
 \int_0^{2\pi} \sin^{n+1} t \, dt &= \left[-\frac{1}{n+1} \sin^n t \cos t \right]_0^{2\pi} + \frac{n}{n+1} \int_0^{2\pi} \sin^{n-1} t \, dt \\
 &= 0 + \frac{n}{n+1} \int_0^{2\pi} \cos^{n-1} t \, dt \\
 &= \frac{n}{n+1} \left(\left[-\frac{1}{n-1} \sin^{n-2} t \cos t \right]_0^{2\pi} + \frac{n-2}{n-1} \int_0^{2\pi} \sin^{n-3} t \, dt \right) \\
 &= \frac{n(n-2)}{(n+1)(n-1)} \int_0^{2\pi} \sin^{n-3} t \, dt.
 \end{aligned}$$

Continuing this process, we will end up with either

$$\begin{aligned}
 \int_0^{2\pi} \sin^{n+1} t \, dt &= \frac{n(n-2) \cdots 2}{(n+1)(n-1) \cdots 3} \int_0^{2\pi} \sin t \, dt = -\frac{n(n-2) \cdots 2}{(n+1)(n-1) \cdots 3} [\cos t]_0^{2\pi} = 0 \\
 \int_0^{2\pi} \sin^{n+1} t \, dt &= \frac{n(n-2) \cdots 1}{(n+1)(n-1) \cdots 2} \int_0^{2\pi} 1 \, dt = 2\pi \frac{n(n-2) \cdots 1}{(n+1)(n-1) \cdots 2},
 \end{aligned}$$

where the first equation applies if n is even and the second if n is odd.

Using these computations in the original integral

$$\int_C (y^n \, dx + x^n \, dy) = ab^n \int_0^{2\pi} \cos^{n+1} t \, dt - ba^n \int_0^{2\pi} \sin^{n+1} t \, dt$$

shows that the integral is 0 if n is even, while if n is odd, we get

$$\begin{aligned}
 2\pi \frac{n(n-2) \cdots 1}{(n+1)(n-1) \cdots 2} (ab^n - ba^n) &= 2\pi ab \frac{n(n-2) \cdots 1}{(n+1)(n-1) \cdots 2} (b^{n-1} - a^{n-1}) \\
 &= 2\pi ab \left(\frac{1}{2} \cdot \frac{3}{4} \cdots \frac{n-2}{n-1} \cdot \frac{n}{n+1} \right) (b^{n-1} - a^{n-1}).
 \end{aligned}$$

61. Using the given parametrization, we have

$$\begin{aligned}
 ds &= \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} \, dt = \sqrt{a^2(1 - \cos t)^2 + a^2 \sin^2 t} \, dt \\
 &= a\sqrt{1 - 2\cos t + \cos^2 t + \sin^2 t} \, dt = a\sqrt{2 - 2\cos t}.
 \end{aligned}$$

The first arch of the cycloid extends from $t = 0$ (since $y(0) = 0$) to $t = 2\pi$, which is the next value of t for which $y(t) = 0$. Then we get

$$\begin{aligned}
 \int_C y^2 \, ds &= \int_0^{2\pi} a^2(1 - \cos t)^2 \cdot a\sqrt{2 - 2\cos t} \, dt \\
 &= a^3\sqrt{2} \int_0^{2\pi} (1 - \cos t)^2 \sqrt{1 - \cos t} \, dt \\
 &= a^3\sqrt{2} \int_0^{2\pi} (1 - \cos t)^{5/2} \, dt.
 \end{aligned}$$

To integrate this, note that since

$$\sin^2 x = \frac{1 - \cos(2x)}{2}, \text{ or } 1 - \cos(2x) = 2\sin^2 x;$$

setting $x = \frac{t}{2}$ gives $1 - \cos t = 2 \sin^2 \frac{t}{2}$. Substituting for $1 - \cos t$ then gives

$$\int_C y^2 ds = a^3 \sqrt{2} \int_0^{2\pi} \left(2 \sin^2 \frac{t}{2} \right)^{5/2} dt = 8a^3 \int_0^{2\pi} \sin^5 \frac{t}{2} dt.$$

Now use the fact that $\sin^2 \frac{t}{2} = 1 - \cos^2 \frac{t}{2}$:

$$\begin{aligned} \int_C y^2 ds &= 8a^3 \int_0^{2\pi} \sin^5 \frac{t}{2} dt \\ &= 8a^3 \int_0^{2\pi} \sin \frac{t}{2} \left(1 - \cos^2 \frac{t}{2} \right)^2 dt \\ &= 8a^3 \int_0^{2\pi} \sin \frac{t}{2} \left(1 - 2 \cos^2 \frac{t}{2} + \cos^4 \frac{t}{2} \right) dt \\ &= 8a^3 \left[-2 \cos \frac{t}{2} + \frac{4}{3} \cos^3 \frac{t}{2} - \frac{2}{5} \cos^5 \frac{t}{2} \right]_0^{2\pi} \\ &= 8a^3 \left(\left(2 - \frac{4}{3} + \frac{2}{5} \right) - \left(-2 + \frac{4}{3} - \frac{2}{5} \right) \right) \\ &= \boxed{\frac{256}{15} a^3}. \end{aligned}$$

62. Using the given parametrization, we have

$$\begin{aligned} ds &= \sqrt{\left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2} dt = \sqrt{a^2(-\sin t + \sin t + t \cos t)^2 + a^2(\cos t - \cos t + t \sin t)^2} dt \\ &= a \sqrt{t^2(\cos^2 t + \sin^2 t)} = at \end{aligned}$$

since $0 \leq t \leq 2\pi$. Also,

$$\begin{aligned} \sqrt{x^2 + y^2} &= \sqrt{a^2(\cos t + t \sin t)^2 + a^2(\sin t - t \cos t)^2} \\ &= a \sqrt{\cos^2 t + 2t \sin t \cos t + t^2 \sin^2 t + \sin^2 t - 2t \sin t \cos t + t^2 \cos^2 t} \\ &= a \sqrt{1 + t^2}. \end{aligned}$$

Therefore

$$\int_C \sqrt{x^2 + y^2} ds = \int_0^{2\pi} a \sqrt{1 + t^2} \cdot at dt = a^2 \int_0^{2\pi} t \sqrt{1 + t^2} dt.$$

Now use the substitution $u = 1 + t^2$, so that $du = 2t dt$; then $t = 0$ corresponds to $u = 1$ and $t = 2\pi$ to $u = 1 + 4\pi^2$, so we get

$$\int_C \sqrt{x^2 + y^2} ds = \frac{1}{2} a^2 \int_1^{1+4\pi^2} u^{1/2} du = \frac{1}{2} a^2 \left[\frac{2}{3} u^{3/2} \right]_1^{1+4\pi^2} = \boxed{\frac{1}{3} a^2 \left((1 + 4\pi^2)^{3/2} - 1 \right)}.$$

63. Using the given parametrization for C , we have

$$\begin{aligned} \int_C (z dx + x dy + y dz) &= \int_C z dx + \int_C x dy + \int_C y dz \\ &= \int_0^{2\pi} t \cdot (-a \sin t) dt + \int_0^{2\pi} a \cos t \cdot (a \cos t) dt + \int_0^{2\pi} a \sin t \cdot 1 dt \\ &= -a \int_0^{2\pi} t \sin t dt + a^2 \int_0^{2\pi} \cos^2 t dt + a \int_0^{2\pi} \sin t dt. \end{aligned}$$

For the first integral, use integration by parts with $u = t$, $dv = \sin t \, dt$, so that $du = dt$ and $v = -\cos t$. Then

$$\begin{aligned}\int_C (z \, dx + x \, dy + y \, dz) &= -a \left([-t \cos t]_0^{2\pi} + \int_0^{2\pi} \cos t \, dt \right) + a^2 \int_0^{2\pi} \left(\frac{1}{2} + \frac{1}{2} \cos(2t) \right) dt + a \int_0^{2\pi} \sin t \, dt \\ &= -a \left(-2\pi + [\sin t]_0^{2\pi} \right) + a^2 \left[\frac{1}{2}t + \frac{1}{4} \sin(2t) \right]_0^{2\pi} + a [-\cos t]_0^{2\pi} \\ &= \boxed{2\pi a + \pi a^2}.\end{aligned}$$

64. Using the given parametrization, we have

$$\begin{aligned}\int_C (xz \, dx + (y+z) \, dy + x \, dz) &= \int_C xz \, dx + \int_C (y+z) \, dy + \int_C x \, dz \\ &= \int_0^1 e^t \cdot e^{2t} \cdot e^t \, dt + \int_0^1 (e^{-t} + e^{2t}) \cdot (-e^{-t}) \, dt \\ &\quad + \int_0^1 e^t \cdot 2e^{2t} \, dt \\ &= \int_0^1 e^{4t} \, dt - \int_0^1 (e^{-2t} + e^t) \, dt + 2 \int_0^1 e^{3t} \, dt \\ &= \left[\frac{1}{4} e^{4t} \right]_0^1 - \left[-\frac{1}{2} e^{-2t} + e^t \right]_0^1 + 2 \left[\frac{1}{3} e^{3t} \right]_0^1 \\ &= \boxed{\frac{1}{4} e^4 + \frac{2}{3} e^3 - e + \frac{1}{2e^2} - \frac{5}{12}}.\end{aligned}$$

65. The mass is $M = \int_C \rho(x, y) \, ds$. Along the curve $y = x^2$, the element ds is

$$ds = \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx = \sqrt{1 + (2x)^2} dx = \sqrt{4x^2 + 1} dx.$$

Therefore we get for the integral

$$M = \int_C \rho(x, y) \, ds = \int_1^2 4x \sqrt{4x^2 + 1} \, dx.$$

Use the substitution $u = 4x^2 + 1$, so that $du = 8x \, dx$; then $x = 1$ corresponds to $u = 5$ while $x = 2$ corresponds to $u = 17$, and

$$M = \frac{1}{2} \int_5^{17} u^{1/2} \, du = \frac{1}{2} \left[\frac{2}{3} u^{3/2} \right]_5^{17} = \boxed{\frac{1}{3} (17\sqrt{17} - 5\sqrt{5})}.$$

66. The mass is $M = \int_C \rho(x, y) \, ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt} \right)^2 + \left(\frac{dy}{dt} \right)^2} = \sqrt{9 \sin^2 t + 9 \cos^2 t} = 3.$$

Therefore we get for the integral

$$M = \int_C \rho(x, y) \, ds = \int_0^{\pi/2} (3 \sin t + 3 \cos t + 1) \cdot 3 \, dt = 3 [-3 \cos t + 3 \sin t + t]_0^{\pi/2} = \boxed{\frac{3\pi}{2} + 18}.$$

67. The mass is $M = \int_C \rho(x, y) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{(4t)^2 + 1^2} = \sqrt{16t^2 + 1}.$$

Therefore we get for the integral

$$M = \int_C \rho(x, y) ds = \int_{-2}^3 3 \cdot 2t^2 \sqrt{16t^2 + 1} dt = 6 \int_{-2}^3 t^2 \sqrt{16t^2 + 1} dt.$$

To evaluate the integral, we use the trigonometric substitution $t = \frac{1}{4} \tan \theta$; then $dt = \frac{1}{4} \sec^2 \theta$, and $\sqrt{16t^2 + 1} = \sqrt{\tan^2 \theta + 1} = \sec \theta$. We are justified in using the positive square root, not the negative one, since $t = -2$ corresponds to $\theta = \tan^{-1}(-8)$ and $t = 3$ to $\theta = \tan^{-1} 12$, and $\sec \theta$ is positive on that range. So we get

$$\begin{aligned} M &= 6 \int_{-2}^3 t^2 \sqrt{16t^2 + 1} dt \\ &= 6 \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \left(\frac{1}{4} \tan \theta\right)^2 \cdot \sec \theta \cdot \frac{1}{4} \sec^2 \theta d\theta \\ &= \frac{3}{32} \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \tan^2 \theta \sec^3 \theta d\theta. \end{aligned}$$

Now use the substitution $\tan^2 \theta = \sec^2 \theta - 1$ and then the reduction formula from Example 8 in Section 7.1:

$$\begin{aligned} \int_C x ds &= \frac{3}{32} \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \tan^2 \theta \sec^3 \theta d\theta \\ &= \frac{3}{32} \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} (\sec^2 \theta - 1) \sec^3 \theta d\theta \\ &= \frac{3}{32} \left(\int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \sec^5 \theta d\theta - \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \sec^3 \theta d\theta \right) \\ &= \frac{3}{32} \left(\left[\frac{\sec^3 \theta \tan \theta}{4} \right]_{\tan^{-1}(-8)}^{\tan^{-1} 12} + \frac{3}{4} \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \sec^3 \theta d\theta - \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \sec^3 \theta d\theta \right) \\ &= \frac{3}{32} \left(\frac{145\sqrt{145} \cdot 12}{4} - \frac{65\sqrt{65} \cdot (-8)}{4} - \frac{1}{4} \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \sec^3 \theta d\theta \right) \\ &= \frac{3}{32} \left(435\sqrt{145} + 130\sqrt{65} - \frac{1}{4} \left(\left[\frac{\sec \theta \tan \theta}{2} \right]_{\tan^{-1}(-8)}^{\tan^{-1} 12} + \frac{1}{2} \int_{\tan^{-1}(-8)}^{\tan^{-1} 12} \sec \theta d\theta \right) \right) \\ &= \frac{1305\sqrt{145} + 390\sqrt{65}}{32} - \frac{3\sqrt{145} \cdot 12}{256} + \frac{3\sqrt{65} \cdot (-8)}{256} - \frac{3}{256} [\ln |\sec \theta + \tan \theta|]_{\tan^{-1}(-8)}^{\tan^{-1} 12} \\ &= \frac{1305\sqrt{145} + 390\sqrt{65}}{32} - \frac{9\sqrt{145} + 6\sqrt{65}}{64} - \frac{3}{256} [\ln |\sec \theta + \tan \theta|]_{\tan^{-1}(-8)}^{\tan^{-1} 12} \\ &= \frac{2601\sqrt{145} + 774\sqrt{65}}{64} - \frac{3}{256} (\ln(\sqrt{145} + 12) - \ln(\sqrt{65} - 8)) \\ &= \boxed{\frac{2601}{64} \sqrt{145} + \frac{387}{32} \sqrt{65} - \frac{3}{256} (\ln(\sqrt{145} + 12) - \ln(\sqrt{65} - 8))}. \end{aligned}$$

68. The mass is $M = \int_C \rho(x, y) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{1^2 + (2t)^2} dt = \sqrt{4t^2 + 1} dt.$$

Therefore we get for the integral

$$M = \int_C \rho(x, y) ds = \int_0^3 t(t^2 - 1 + 1) \sqrt{4t^2 + 1} dt = \int_0^3 t^3 \sqrt{4t^2 + 1} dt.$$

To evaluate the integral, we use the trigonometric substitution $t = \frac{1}{2} \tan \theta$; then $dt = \frac{1}{2} \sec^2 \theta$, and $\sqrt{4t^2 + 1} = \sqrt{\tan^2 \theta + 1} = \sec \theta$. We are justified in using the positive square root, not the negative one, since $t = 0$ corresponds to $\theta = 0$ and $t = 3$ to $\theta = \tan^{-1} 6$, and $\sec \theta$ is positive on that range. So we get

$$M = \int_0^{\tan^{-1} 6} \left(\frac{1}{2} \tan \theta\right)^3 \cdot \sec \theta \cdot \frac{1}{2} \sec^2 \theta d\theta = \frac{1}{16} \int_0^{\tan^{-1} 6} \tan^3 \theta \sec^3 \theta d\theta.$$

Now replace a factor of $\tan^2 \theta$ by $\sec^2 \theta - 1$, giving

$$M = \frac{1}{16} \int_0^{\tan^{-1} 6} \tan \theta (\sec^2 \theta - 1) \sec^3 \theta d\theta = \frac{1}{16} \int_0^{\tan^{-1} 6} (\sec^4 \theta - \sec^2 \theta) \tan \theta \sec \theta d\theta.$$

Finally, use the substitution $u = \sec \theta$, so that $du = \tan \theta \sec \theta$. Then $\theta = 0$ corresponds to $u = \sec 0 = 1$, and $\theta = \tan^{-1} 6$ corresponds to $u = \sec(\tan^{-1} 6) = \sqrt{37}$, and we get

$$M = \frac{1}{16} \int_1^{\sqrt{37}} (u^4 - u^2) du = \frac{1}{16} \left[\frac{1}{5} u^5 - \frac{1}{3} u^3 \right]_1^{\sqrt{37}} = \boxed{\frac{1 + 1961\sqrt{37}}{120}}.$$

69. The mass is $M = \int_C \rho(x, y) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{4 \sin^2 t + 4 \cos^2 t + 1} = \sqrt{5}.$$

Two turns of the spring corresponds to the range $0 \leq \theta \leq 4\pi$. Therefore we get for the integral

$$M = \int_C \rho(x, y, z) ds = \int_0^{4\pi} \rho \sqrt{5} dt = \boxed{4\pi \rho \sqrt{5}}.$$

70. The mass is $M = \int_C \rho(x, y) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{9 \sin^2 t + 9 \cos^2 t + 1} = \sqrt{10}.$$

Two turns of the spring corresponds to the range $0 \leq \theta \leq 4\pi$. Therefore we get for the integral

$$M = \int_C \rho(x, y, z) ds = \int_0^{4\pi} (t + 2) \sqrt{10} dt = \sqrt{10} \left[\frac{1}{2} t^2 + 2t \right]_0^{4\pi} = \boxed{\sqrt{10} (8\pi^2 + 8\pi)}.$$

71. By analogy with the formula for the mass of a wire in the plane, the formula is

$$\boxed{M = \int_C \rho(x, y, z) ds}.$$

72. The mass is $M = \int_C \rho(x, y, z) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{4 \sin^2 t + 4 \cos^2 t + 25} = \sqrt{29}.$$

Therefore we get for the integral

$$M = \int_C \rho(x, y, z) ds = \int_0^{2\pi} k \sqrt{29} dt = \boxed{2\pi k \sqrt{29}}.$$

73. The mass is $M = \int_C \rho(x, y, z) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{9\sin^2 t + 9\cos^2 t + 16} = \sqrt{25} = 5.$$

Therefore we get for the integral

$$M = \int_C \rho(x, y, z) ds = \int_0^{2\pi} (2 + 4t) \cdot 5 dt = 5 [2t + 2t^2]_0^{2\pi} = 5(4\pi + 8\pi^2) = \boxed{20(\pi + 2\pi^2)}.$$

74. The mass is $M = \int_C \rho(x, y, z) ds$. Along the given parametrized curve, the element ds is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{4\sin^2 t + 4\cos^2 t + 25} = \sqrt{29}.$$

The mass density is

$$k(x^2 + y^2 + z^2) = k(4\cos^2 t + 4\sin^2 t + 25t^2) = k(25t^2 + 4).$$

Therefore we get for the integral

$$\begin{aligned} M &= \int_C \rho(x, y, z) ds \\ &= k \int_0^{2\pi} (25t^2 + 4) \cdot \sqrt{29} dt \\ &= k\sqrt{29} \int_0^{2\pi} (25t^2 + 4) dt \\ &= k\sqrt{29} \left[\frac{25}{3}t^3 + 4t \right]_0^{2\pi} \\ &= \boxed{k\sqrt{29} \left(\frac{200}{3}\pi^3 + 8\pi \right)}. \end{aligned}$$

75. Parametrize the circle by $x = R \cos t$, $y = R \sin t$, $0 \leq t \leq 2\pi$. Then

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{R^2 \sin^2 t + R^2 \cos^2 t} = R.$$

Then we get for the lateral surface area

$$A = \int_C f(x, y) dx = \int_0^{2\pi} hR dt = \boxed{2\pi Rh}.$$

76. We have two parametrizations:

$$\begin{aligned} C_1 : x &= \cos \theta, \quad y = \sin \theta, \quad x' = -\sin \theta, \quad y' = \cos \theta, \quad 0 \leq \theta \leq 4\pi \\ C_2 : x &= \cos(t^2), \quad y = \sin(t^2), \quad x' = -2t \sin(t^2), \quad y' = 2t \cos(t^2), \quad 0 \leq t \leq 2\sqrt{\pi}. \end{aligned}$$

Then

$$\int_{C_1} (P dx + Q dy) = \int_0^{4\pi} (\cos^3 \theta \sin \theta \cdot (-\sin \theta) + \sin^2 \theta \cos \theta \cdot (\cos \theta)) d\theta.$$

Now make the substitution $t = \sqrt{\theta}$, so that $\theta = t^2$ and $d\theta = 2t dt$. Then $\theta = 0$ corresponds to $t = 0$ and $\theta = 4\pi$ to $t = 2\sqrt{\pi}$, and the integral becomes

$$\int_{C_1} (P dx + Q dy) = \int_0^{2\sqrt{\pi}} (\cos^3(t^2) \sin(t^2) \cdot (-\sin(t^2)) + \sin^2(t^2) \cos(t^2) \cos(t^2)) 2t dt.$$

Now look at the other integral:

$$\begin{aligned}\int_{C_2} (P dx + Q dy) &= \int_0^{2\sqrt{\pi}} (\cos^3(t^2) \sin(t^2) \cdot (-2t \sin(t^2)) + \sin^2(t^2) \cos(t^2) \cdot (2t \cos(t^2))) dt \\ &= \int_0^{2\sqrt{\pi}} (\cos^3(t^2) \sin(t^2) \cdot (-\sin(t^2)) + \sin^2(t^2) \cos(t^2) \cos(t^2)) 2t dt.\end{aligned}$$

This is the same as the first integral after the substitution. The reason that these two are the same is that the two curves trace exactly the same path, but at different speeds, as t and θ vary over their ranges.

Challenge Problems

77. With the given parametrization, we have

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt = \sqrt{1^2 + (3\sqrt{2}t)^2} dt = \sqrt{18t^2 + 1} dt.$$

Then the integral is

$$\int_C (x + y) ds = \int_0^1 \left(t + \frac{3}{\sqrt{2}}t^2\right) \sqrt{18t^2 + 1} dt = \int_0^1 t \sqrt{18t^2 + 1} dt + \frac{3}{\sqrt{2}} \int_0^1 t^2 \sqrt{18t^2 + 1} dt.$$

For the first integral, use the substitution $u = 18t^2 + 1$, so that $du = 36t dt$; then $t = 0$ corresponds to $u = 1$ while $t = 1$ corresponds to $u = 19$. For the second integral, use the trigonometric substitution $t = \frac{1}{\sqrt{18}} \tan \theta$; then $18t^2 + 1 = \sec^2 \theta$ and $dt = \frac{1}{\sqrt{18}} \sec^2 \theta d\theta$. Here $t = 0$ corresponds to $\theta = 0$ and $t = 1$ to $\theta = \tan^{-1} \sqrt{18}$. So we get

$$\begin{aligned}\int_C (x + y) ds &= \frac{1}{36} \int_1^{19} u^{1/2} du + \frac{3}{\sqrt{2}} \int_0^{\tan^{-1} \sqrt{18}} \left(\frac{1}{\sqrt{18}} \tan \theta\right)^2 \cdot \sec \theta \cdot \frac{1}{\sqrt{18}} \sec^2 \theta d\theta \\ &= \frac{1}{36} \left[\frac{2}{3} u^{3/2}\right]_1^{19} + \frac{1}{36} \int_0^{\tan^{-1} \sqrt{18}} \tan^2 \theta \sec^3 \theta d\theta\end{aligned}$$

Now use the substitution $\tan^2 \theta = \sec^2 \theta - 1$ and then the reduction formula from Example 8 in Section 7.1:

$$\begin{aligned}
 \int_C (x + y) ds &= \frac{1}{36} \left[\frac{2}{3} u^{3/2} \right]_1^{19} + \frac{1}{36} \int_0^{\tan^{-1} \sqrt{18}} \tan^2 \theta \sec^3 \theta d\theta \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{1}{36} \int_0^{\tan^{-1} \sqrt{18}} (\sec^2 \theta - 1) \sec^3 \theta d\theta \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{1}{36} \left(\int_0^{\tan^{-1} \sqrt{18}} \sec^5 \theta d\theta - \int_0^{\tan^{-1} \sqrt{18}} \sec^3 \theta d\theta \right) \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{1}{36} \left(\left[\frac{\sec^3 \theta \tan \theta}{4} \right]_0^{\tan^{-1} \sqrt{18}} \right. \\
 &\quad \left. + \frac{3}{4} \int_0^{\tan^{-1} \sqrt{18}} \sec^3 \theta d\theta - \int_0^{\tan^{-1} \sqrt{18}} \sec^3 \theta d\theta \right) \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{1}{36} \left(\frac{19\sqrt{19}\sqrt{18}}{4} - \frac{1}{4} \int_0^{\tan^{-1} \sqrt{18}} \sec^3 \theta d\theta \right) \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{1}{36} \left(\frac{19\sqrt{19}\sqrt{18}}{4} \right. \\
 &\quad \left. - \frac{1}{4} \left(\left[\frac{\sec \theta \tan \theta}{2} \right]_0^{\tan^{-1} \sqrt{18}} + \frac{1}{2} \int_0^{\tan^{-1} \sqrt{18}} \sec \theta d\theta \right) \right) \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{19\sqrt{19}\sqrt{18}}{144} - \frac{\sqrt{19}\sqrt{18}}{288} - \frac{1}{288} [\ln |\sec \theta + \tan \theta|]_0^{\tan^{-1} \sqrt{18}} \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{19\sqrt{19}\sqrt{18}}{144} - \frac{\sqrt{19}\sqrt{18}}{288} - \frac{1}{288} \ln(\sqrt{19} + \sqrt{18}) \\
 &= \frac{1}{54} (19\sqrt{19} - 1) + \frac{57\sqrt{38}}{144} - \frac{3\sqrt{38}}{288} - \frac{1}{288} \ln(\sqrt{19} + \sqrt{18}) \\
 &= \boxed{\frac{1}{54} (19\sqrt{19} - 1) + \frac{37\sqrt{38}}{96} - \frac{1}{288} \ln(\sqrt{19} + 3\sqrt{2})}.
 \end{aligned}$$

78. The hypocycloid (with $a = 1$) for $0 \leq t \leq 2\pi$ is

Since the wire is homogeneous, we assume its mass density is 1, by changing units if necessary.

(a) With the given parametrization, we have

$$\begin{aligned}
 ds &= \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\
 &= \sqrt{(3a \cos^2 t (-\sin t))^2 + (3a \sin^2 t \cos t)^2} dt \\
 &= \sqrt{9a^2 \cos^4 t \sin^2 t + 9a^2 \sin^4 t \cos^2 t} dt \\
 &= 3a \sqrt{\cos^2 t \sin^2 t (\cos^2 t + \sin^2 t)} dt \\
 &= 3a \sin t \cos t.
 \end{aligned}$$

Then the mass of one arm of the hypocycloid is

$$M = \int_0^{\pi/2} 1 ds = 3a \int_0^{\pi/2} \sin t \cos t dt = \frac{3a}{2} \int_0^{\pi/2} \sin(2t) dt = \frac{3a}{2} \left[-\frac{1}{2} \cos(2t) \right]_0^{\pi/2} = \frac{3a}{2}.$$

Then

$$\begin{aligned}
 M_y &= \int_C x ds \\
 &= \int_0^{\pi/2} a \cos^3 t \cdot 3a \sin t \cos t dt \\
 &= 3a^2 \int_0^{\pi/2} \cos^4 t \sin t dt \\
 &= 3a^2 \left[-\frac{1}{5} \cos^5 t \right]_0^{\pi/2} = \frac{3}{5} a^2,
 \end{aligned}$$

so that

$$\bar{x} = \frac{M_y}{M} = \frac{\frac{3}{5}a^2}{\frac{3}{2}a} = \frac{2}{5}a.$$

By symmetry, $\bar{y} = \frac{2}{5}a$ as well, so that the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{2}{5}a, \frac{2}{5}a \right).$$

(b) By symmetry, the center of mass lies at the origin.

79. (a) In the definition of the line integral of f along C , Δs_i is the distance from $(x(t_{i-1}), y(t_{i-1}))$ to $(x(t_i), y(t_i))$, so it is

$$\begin{aligned}
 \Delta s_i &= \sqrt{(x(t_i) - x(t_{i-1}))^2 + (y(t_i) - y(t_{i-1}))^2} \\
 &= \sqrt{\left(\frac{x(t_i) - x(t_{i-1})}{t_i - t_{i-1}}\right)^2 + \left(\frac{y(t_i) - y(t_{i-1})}{t_i - t_{i-1}}\right)^2} (t_i - t_{i-1}).
 \end{aligned}$$

Now, $x(t)$ is continuous, so that by the Mean Value Theorem, there is some $t_i^* \in [t_{i-1}, t_i]$ such that

$$\frac{dx}{dt}(t_i^*) = \frac{x(t_i) - x(t_{i-1})}{t_i - t_{i-1}},$$

and similarly there is some $u_i^* \in [t_{i-1}, t_i]$ such that

$$\frac{dy}{dt}(u_i^*) = \frac{y(t_i) - y(t_{i-1})}{t_i - t_{i-1}}.$$

So the equation for Δs_i becomes

$$\Delta s_i = \sqrt{\left(\frac{dx}{dt}(t_i^*)\right)^2 + \left(\frac{dy}{dt}(u_i^*)\right)^2} (t_i - t_{i-1}) = \sqrt{\left(\frac{dx}{dt}(t_i^*)\right)^2 + \left(\frac{dy}{dt}(u_i^*)\right)^2} \Delta t.$$

Substituting into the definition of the line integral gives

$$\begin{aligned} \int_C f(x, y) ds &= \lim_{\|\Delta\| \rightarrow 0} \sum_{i=1}^n f(x_i^*, y_i^*) \Delta s_i \\ &= \lim_{\|\Delta\| \rightarrow 0} \sum_{i=1}^n f(x_i^*, y_i^*) \sqrt{\left(\frac{dx}{dt}(t_i^*)\right)^2 + \left(\frac{dy}{dt}(u_i^*)\right)^2} \Delta t \\ &= \int_a^b f(x(t), y(t)) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt. \end{aligned}$$

- (b) We know that $\int_C f(x, y) ds = \lim_{\|\Delta\| \rightarrow 0} \sum_{i=1}^n f(x_i^*, y_i^*) \Delta s$. A parametrization of C gives $x(t)$ and $y(t)$ for $a \leq t \leq b$, and then

$$s(t) = \int_a^t \sqrt{x'(u)^2 + y'(u)^2} du$$

is the length of arc traced at each value t , so that $\Delta s = s_{i+1} - s_i = s(t_{i+1}) - s(t_i)$. By the Mean Value Theorem, there is some $t_i^* \in [t_i, t_{i+1}]$ such that

$$s(t_{i+1}) - s(t_i) = s'(t_i^*) \Delta t = \sqrt{x'(t_i^*)^2 + y'(t_i^*)^2} \Delta t.$$

Therefore

$$\begin{aligned} \int_C f(x, y) ds &= \lim_{\|\Delta\| \rightarrow 0} \sum_{i=1}^n f(x_i^*, y_i^*) \Delta s \\ &= \lim_{\|\Delta\| \rightarrow 0} \sum_{i=1}^n f(x(t_i^*), y(t_i^*)) \sqrt{x'(t_i^*)^2 + y'(t_i^*)^2} \Delta t \\ &= \int_a^b f(x(t), y(t)) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt. \end{aligned}$$

80. If C is expressed as $(x(s), y(s))$ where the parameter s represents arc length, then the arc length from $s = 0$ to $s = a$ is

$$\int_0^a 1 ds = \int_0^a \sqrt{\left(\frac{dx}{ds}\right)^2 + \left(\frac{dy}{ds}\right)^2} ds.$$

Therefore $\sqrt{\left(\frac{dx}{ds}\right)^2 + \left(\frac{dy}{ds}\right)^2} = 1$, so the integral becomes

$$\int_C f(x, y) dx = \int_a^b f(x(s), y(s)) ds.$$

81. (a) If $P = P(x, y)$ and $Q = Q(x, y)$ and C is parametrized using the arc length parameter s , then

$$\begin{aligned} P(x, y) dx + Q(x, y) dy &= P(x, y) x'(s) ds + Q(x, y) y'(s) ds \\ &= (P(x(s), y(s)) x'(s) + Q(x(s), y(s)) y'(s)) ds. \end{aligned}$$

Then $f(s) = P(x(s), y(s)) x'(s) + Q(x(s), y(s)) y'(s)$.

(b) Suppose $s = s(x, y)$. Then

$$ds = \frac{\partial s}{\partial x} dx + \frac{\partial s}{\partial y} dy,$$

so that

$$\int_C f ds = \int_C f \left(\frac{\partial s}{\partial x} dx + \frac{\partial s}{\partial y} dy \right) = \int_C \left(f \frac{\partial s}{\partial x} \right) dx + \left(f \frac{\partial s}{\partial y} \right) dy.$$

Applying this to the example given, we have $s = \sqrt{x^2 + y^2}$, since C parametrizes the line $y = x$ for $0 \leq x \leq 1$. Then

$$\frac{\partial s}{\partial x} = \frac{x}{\sqrt{x^2 + y^2}}, \quad \frac{\partial s}{\partial y} = \frac{y}{\sqrt{x^2 + y^2}},$$

so that by the above,

$$\begin{aligned} \int_C (x + y^2) ds &= \int_C \left(\left((x + y^2) \cdot \frac{x}{\sqrt{x^2 + y^2}} \right) dx + \left((x + y^2) \cdot \frac{y}{\sqrt{x^2 + y^2}} \right) dy \right) \\ &= \int_C \left[\frac{x^2 + xy^2}{\sqrt{x^2 + y^2}} dx + \frac{xy + y^3}{\sqrt{x^2 + y^2}} dy \right]. \end{aligned}$$

15.3: Fundamental Theorem of Line Integrals

Concepts and Vocabulary

1. False. In fact f is a potential function for $\mathbf{F}$, not the other way around.
2. (d) is correct. See the discussion at the end of Objective 1.
3. True. This is part of the content of the Fundamental Theorem of Line Integrals.
4. (c) is correct. See the definition at the start of this section.
5. A piecewise-smooth curve C is *closed* if its initial point (x_0, y_0) and its terminal point (x_1, y_1) are the same.
6. $\int \mathbf{F} \cdot d\mathbf{r} = 0$. See Value of a Line Integral over a Closed Curve.
7. False. What is required is that *any* two points can be connected by such a curve. This is defined in Objective 2.
8. True. See the discussion of the converse in the text.
9. False. C is closed if $\mathbf{r}(a) = \mathbf{r}(b)$.
10. True. A simple curve is one that does not intersect itself; this is true of a parabola.
11. False. See the definition in Objective 4.
12. If and only if $\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$; see Conservative Vector Field Test in the text.

Skill Building

13. The given vector field, $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j} = e^x \cos y \mathbf{i} - e^x \sin y \mathbf{j}$ is conservative. To see this, note that both P and Q as well as their derivatives are continuous on all of the plane, and that

$$\frac{\partial P}{\partial y} = -e^x \sin y = \frac{\partial Q}{\partial x}.$$

So once we find a potential function, we can evaluate the three line integrals given. To find a potential function, start by integrating $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int e^x \cos y dx = e^x \cos y + h(y).$$

Then we want the partial derivative with respect to y of this function to equal $Q(x, y)$:

$$\frac{\partial}{\partial y} (e^x \cos y + h(y)) = -e^x \sin y + h'(y) = -e^x \sin y,$$

so that $h'(y) = 0$ and h is a constant. So $f(x, y) = e^x \cos y + K$ is a potential function for $\mathbf{F}$. Therefore:

(a) This is a piecewise smooth parametrization with endpoints $(0, \frac{\pi}{3})$ and $(1, \pi)$, so that

$$\int_C (e^x \cos y dx - e^x \sin y dy) = f(1, \pi) - f\left(0, \frac{\pi}{3}\right) = \boxed{-e - \frac{1}{2}}.$$

(b) This is a smooth parametrization with endpoints $(0, \frac{\pi}{3})$ and $(1, \pi)$, so that again

$$\int_C (e^x \cos y dx - e^x \sin y dy) = f(1, \pi) - f\left(0, \frac{\pi}{3}\right) = \boxed{-e - \frac{1}{2}}.$$

(c) This is another piecewise smooth parametrization with endpoints $(0, \frac{\pi}{3})$ and $(1, \pi)$, so that

$$\int_C (e^x \cos y dx - e^x \sin y dy) = f(1, \pi) - f\left(0, \frac{\pi}{3}\right) = \boxed{-e - \frac{1}{2}}.$$

14. The given vector field, $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j} = e^y \cos x \mathbf{i} + e^y \sin x \mathbf{j}$ is conservative. To see this, note that both P and Q as well as their derivatives are continuous on all of the plane, and that

$$\frac{\partial P}{\partial y} = e^y \cos x = \frac{\partial Q}{\partial x}.$$

So once we find a potential function, we can evaluate the three line integrals given. To find a potential function, start by integrating $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int e^y \cos x dx = e^y \sin x + h(y).$$

Then we want the partial derivative with respect to y of this function to equal $Q(x, y)$:

$$\frac{\partial}{\partial y} (e^y \sin x + h(y)) = e^y \sin x + h'(y) = e^y \sin x,$$

so that $h'(y) = 0$ and h is a constant. So $f(x, y) = e^y \sin x + K$ is a potential function for $\mathbf{F}$. Therefore:

(a) This is a smooth parametrization with endpoints $(0, 0)$ and $(\pi, 1)$, so that

$$\int_C (e^y \cos x dx + e^y \sin x dy) = f(\pi, 1) - f(0, 0) = 0 - 0 = \boxed{0}.$$

(b) This is a piecewise smooth parametrization with endpoints $(0, 0)$ and $(\pi, 1)$, so that again

$$\int_C (e^y \cos x dx + e^y \sin x dy) = f(\pi, 1) - f(0, 0) = 0 - 0 = \boxed{0}.$$

(c) This is another piecewise smooth parametrization with endpoints $(0, 0)$ and $(\pi, 1)$, so that

$$\int_C (e^y \cos x \, dx + e^y \sin x \, dy) = f(\pi, 1) - f(0, 0) = 0 - 0 = \boxed{0}.$$

15. By the Fundamental Theorem of Line Integrals,

$$\int_C [(2x - y) \, dx + (2y - x) \, dy] = f(5, 4) - f(3, -1) = (5^2 - 5 \cdot 4 + 4^2) - (3^2 - 3 \cdot (-1) + (-1)^2) = \boxed{8}.$$

16. By the Fundamental Theorem of Line Integrals,

$$\int_C [(y^2 + 2x) \, dx + 2xy \, dy] = f(-3, 8) - f(2, 2) = (-3 \cdot 8^2 + (-3)^2) - (2 \cdot 2^2 + 2^2) = \boxed{-195}.$$

17. By the Fundamental Theorem of Line Integrals,

$$\int_C (3x^2y \, dx + x^3 \, dy) = f(3, 4) - f(0, -1) = 3^3 \cdot 4 - 0^3 \cdot (-1) = \boxed{108}.$$

18. By the Fundamental Theorem of Line Integrals,

$$\int_C (2xe^{x^2+y^2} \, dx + 2ye^{x^2+y^2} \, dy) = f(1, 1) - f(0, 0) = e^{1^2+1^2} - e^{0^2+0^2} = \boxed{e^2 - 1}.$$

19. By the Fundamental Theorem of Line Integrals,

$$\begin{aligned} \int_C \left(\frac{x}{x^2 + y^2} \, dx + \frac{y}{x^2 + y^2} \, dy \right) &= f(5, 12) - f(3, 4) = \ln \sqrt{5^2 + 12^2} - \ln \sqrt{3^2 + 4^2} \\ &= \boxed{\ln 13 - \ln 5 = \ln \frac{13}{5}}. \end{aligned}$$

20. By the Fundamental Theorem of Line Integrals,

$$\int_C \left(\frac{x}{\sqrt{x^2 + y^2}} \, dx + \frac{y}{\sqrt{x^2 + y^2}} \, dy \right) = f(3, 4) - f(0, -4) = \sqrt{3^2 + 4^2} - \sqrt{0^2 + (-4)^2} = 5 - 4 = \boxed{1}.$$

21. Since $\mathbf{F}$ is conservative, and $P(x, y)$, $Q(x, y)$, and their derivatives are continuous everywhere, we may choose any piecewise smooth path from $(1, 1)$ to $(2, 4)$. Choose the path consisting of

$$\begin{aligned} C_1 : (1, 1) \text{ to } (2, 1), \quad x &= 1 + t, \, y = 1, \, 0 \leq t \leq 1 \\ C_2 : (2, 1) \text{ to } (2, 4), \quad x &= 2, \, y = 1 + 3t, \, 0 \leq t \leq 1. \end{aligned}$$

Then

$$\begin{aligned} \int_C (x^3 \, dx + y^3 \, dy) &= \int_{C_1} (x^3 \, dx + y^3 \, dy) + \int_{C_2} (x^3 \, dx + y^3 \, dy) \\ &= \int_0^1 ((1+t)^3 \cdot 1 + 1^3 \cdot 0) \, dt + \int_0^1 (2^3 \cdot 0 + (1+3t)^3 \cdot 3) \, dt \\ &= \int_0^1 (1+t)^3 \, dt + 3 \int_0^1 (1+3t)^3 \, dt \\ &= \left[\frac{1}{4}(1+t)^4 \right]_0^1 + 3 \left[\frac{1}{12}(1+3t)^4 \right]_0^1 \\ &= \left(4 - \frac{1}{4} \right) + 3 \left(\frac{64}{3} - \frac{1}{12} \right) \\ &= \boxed{\frac{135}{2}}. \end{aligned}$$

22. Since $\mathbf{F}$ is conservative, and $P(x, y)$, $Q(x, y)$, and their derivatives are continuous everywhere, we may choose any piecewise smooth path from $(-1, 2)$ to $(2, 3)$. Choose the path consisting of

$$C_1 : (-1, 2) \text{ to } (2, 2), \quad x = -1 + t, \quad y = 2, \quad 0 \leq t \leq 3$$

$$C_2 : (2, 2) \text{ to } (2, 3), \quad x = 2, \quad y = 2 + t, \quad 0 \leq t \leq 1.$$

Then

$$\begin{aligned} \int_C (2x^2 dx - 4y dy) &= \int_{C_1} (2x^2 dx - 4y dy) + \int_{C_2} (2x^2 dx - 4y dy) \\ &= \int_0^3 (2(-1+t)^2 \cdot 1 - 4 \cdot 2 \cdot 0) dt + \int_0^1 (2 \cdot 2^2 \cdot 0 - 4(2+t) \cdot 1) dt \\ &= \int_0^3 2(t-1)^2 dt - \int_0^1 (8+4t) dt \\ &= \left[\frac{2}{3}(t-1)^3 \right]_0^3 - [8t + 2t^2]_0^1 \\ &= \left(\frac{16}{3} + \frac{2}{3} \right) - (10 - 0) = \boxed{-4}. \end{aligned}$$

23. Since $\mathbf{F}$ is conservative, and $P(x, y)$, $Q(x, y)$, and their derivatives are continuous everywhere, we may choose any piecewise smooth path from $(0, 0)$ to $(2, 0)$. Choose the path parametrized as $x = 2t$, $y = 0$ for $0 \leq t \leq 1$. Then

$$\begin{aligned} \int_C [(x^2 + y^2) dx + (2xy + \sin y) dy] &= \int_0^1 [((2t)^2 + 0^2) \cdot 2 + (2 \cdot 2t \cdot 0 + \sin 0) \cdot 0] dt \\ &= \int_0^1 8t^2 dt \\ &= \left[\frac{8}{3}t^3 \right]_0^1 = \boxed{\frac{8}{3}}. \end{aligned}$$

24. Since $\mathbf{F}$ is conservative, and $P(x, y)$, $Q(x, y)$, and their derivatives are continuous everywhere, we may choose any piecewise smooth path from $(1, \frac{\pi}{2})$ to $(2, \pi)$. Choose the path consisting of

$$C_1 : \left(1, \frac{\pi}{2}\right) \text{ to } \left(2, \frac{\pi}{2}\right), \quad x = 1 + t, \quad y = \frac{\pi}{2}, \quad 0 \leq t \leq 1$$

$$C_2 : \left(2, \frac{\pi}{2}\right) \text{ to } (2, \pi), \quad x = 2, \quad y = \frac{\pi}{2}(t+1), \quad 0 \leq t \leq 1.$$

Then

$$\begin{aligned} \int_C [(x - \cos y) dx + x \sin y dy] &= \int_{C_1} [(x - \cos y) dx + x \sin y dy] + \int_{C_2} [(x - \cos y) dx + x \sin y dy] \\ &= \int_0^1 \left[\left((t+1) - \cos \frac{\pi}{2} \right) \cdot 1 + (t+1) \sin \frac{\pi}{2} \cdot 0 \right] dt \\ &\quad + \int_0^1 \left[\left(2 - \cos \left(\frac{\pi}{2}(t+1) \right) \right) \cdot 0 + 2 \sin \left(\frac{\pi}{2}(t+1) \right) \cdot \frac{\pi}{2} \right] dt \\ &= \int_0^1 (t+1) dt + \int_0^1 \pi \sin \left(\frac{\pi}{2}(t+1) \right) dt \\ &= \left[\frac{1}{2}(t+1)^2 \right]_0^1 + \pi \left[-\frac{2}{\pi} \cos \left(\frac{\pi}{2}(t+1) \right) \right]_0^1 \\ &= \left(2 - \frac{1}{2} \right) + \pi \left(-\frac{2}{\pi} \cdot (-1) + \frac{2}{\pi} \cdot 0 \right) \\ &= \boxed{\frac{7}{2}}. \end{aligned}$$

25. Since $\mathbf{F}$ is conservative, and $P(x, y)$, $Q(x, y)$, and their derivatives are continuous everywhere, we may choose any piecewise smooth path from $(0, 0)$ to $(\ln 2, 2)$. Choose the path consisting of

$$\begin{aligned} C_1 : (0, 0) \text{ to } (\ln 2, 0), \quad x = t \ln 2, \quad y = 0, \quad 0 \leq t \leq 1 \\ C_2 : (\ln 2, 0) \text{ to } (\ln 2, 2), \quad x = \ln 2, \quad y = 2t, \quad 0 \leq t \leq 1. \end{aligned}$$

Then

$$\begin{aligned} \int_C (y^2 e^x dx + 2ye^x dy) &= \int_{C_1} (y^2 e^x dx + 2ye^x dy) + \int_{C_2} (y^2 e^x dx + 2ye^x dy) \\ &= \int_0^1 (0^2 \cdot e^{t \ln 2} \cdot \ln 2 + 2 \cdot 0 \cdot e^{t \ln 2} \cdot 0) dt \\ &\quad + \int_0^1 ((2t)^2 e^{\ln 2} \cdot 0 + 2 \cdot 2t \cdot e^{\ln 2} \cdot 2) dt \\ &= \int_0^1 16t dt \\ &= [8t^2]_0^1 = \boxed{8}. \end{aligned}$$

26. Since $\mathbf{F}$ is conservative, and $P(x, y)$, $Q(x, y)$, and their derivatives are continuous everywhere, we may choose any piecewise smooth path from $(0, 0)$ to $(2, 1)$. Choose the path consisting of

$$\begin{aligned} C_1 : (0, 0) \text{ to } (2, 0), \quad x = 2t, \quad y = 0, \quad 0 \leq t \leq 1 \\ C_2 : (2, 0) \text{ to } (2, 1), \quad x = 2, \quad y = t, \quad 0 \leq t \leq 1. \end{aligned}$$

Then

$$\begin{aligned} \int_C \left[xe^y dx + \frac{1}{2}(x^2 - 4)e^y dy \right] &= \int_{C_1} \left[xe^y dx + \frac{1}{2}(x^2 - 4)e^y dy \right] + \int_{C_2} \left[xe^y dx + \frac{1}{2}(x^2 - 4)e^y dy \right] \\ &= \int_0^1 \left[2t \cdot e^0 \cdot 2 + \frac{1}{2}((2t)^2 - 4)e^0 \cdot 0 \right] dt \\ &\quad + \int_0^1 \left[2 \cdot e^t \cdot 0 + \frac{1}{2}(2^2 - 4) \cdot e^t \cdot 1 \right] dt \\ &= \int_0^1 4t dt \\ &= [2t^2]_0^1 = \boxed{2}. \end{aligned}$$

27. Since $\mathbf{F}$ is conservative and C is a closed curve, the line integral is zero by Value of a Line Integral over a Closed Curve.
28. Since $\mathbf{F}$ is conservative and C is a closed curve, the line integral is zero by Value of a Line Integral over a Closed Curve.
29. We have $P(x, y) = 5x - 2y + 1$ and $Q(x, y) = 4 - 2x$. Start by integrating P with respect to x :

$$\int P(x, y) dx = \int (5x - 2y + 1) dx = \frac{5}{2}x^2 - 2xy + x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 - 2x + 0 + h'(y) = 4 - 2x,$$

so that $h'(y) = 4$. Integrating with respect to y gives $h(y) = 4y + K$ where K is a constant. So

$$\boxed{f(x, y) = \frac{5}{2}x^2 - 2xy + x + 4y + K}.$$

30. We have $P(x, y) = 4xy$ and $Q(x, y) = 2x^2 + y$. Start by integrating P with respect to x :

$$\int P(x, y) dx = \int 4xy dx = 2x^2y + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$2x^2 + h'(y) = 2x^2 + y,$$

so that $h'(y) = y$. Integrating with respect to y gives $h(y) = \frac{1}{2}y^2 + K$ where K is a constant. So

$$\boxed{f(x, y) = 2x^2y + \frac{1}{2}y^2 + K}.$$

31. We have $P(x, y) = \ln y + 2x$ and $Q(x, y) = \frac{x}{y}$. Start by integrating P with respect to x :

$$\int P(x, y) dx = \int (\ln y + 2x) dx = x \ln y + x^2 + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$\frac{x}{y} + 0 + h'(y) = \frac{x}{y},$$

so that $h'(y) = 0$. Integrating with respect to y gives $h(y) = K$ where K is a constant. So

$$\boxed{f(x, y) = x \ln y + x^2 + K}.$$

32. We have $P(x, y) = ye^x$ and $Q(x, y) = e^x$. Start by integrating P with respect to x :

$$\int P(x, y) dx = \int ye^x dx = ye^x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$e^x + h'(y) = e^x,$$

so that $h'(y) = 0$. Integrating with respect to y gives $h(y) = K$ where K is a constant. So

$$\boxed{f(x, y) = ye^x + K}.$$

33. We have $P(x, y) = x^2$ and $Q(x, y) = y^2$. Since P , Q , and their derivatives are continuous everywhere, and $\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x}$, the Conservative Vector Field Test tells us that $\mathbf{F}$ is conservative.
34. We have $P(x, y) = xy$ and $Q(x, y) = xy$. Since P , Q , and their derivatives are continuous everywhere, and $\frac{\partial P}{\partial y} = x$ while $\frac{\partial Q}{\partial x} = y$, the Conservative Vector Field Test tells us that $\mathbf{F}$ is not conservative.
35. We have $P(x, y) = xe^y$ and $Q(x, y) = \frac{1}{2}x^2e^y$. Since P , Q , and their derivatives are continuous everywhere, and $\frac{\partial P}{\partial y} = xe^y = \frac{\partial Q}{\partial x}$, the Conservative Vector Field Test tells us that $\mathbf{F}$ is conservative.
36. We have $P(x, y) = x^2 + y^2$ and $Q(x, y) = 2xy - \sin y$. Since P , Q , and their derivatives are continuous everywhere, and $\frac{\partial P}{\partial y} = 2y = \frac{\partial Q}{\partial x}$, the Conservative Vector Field Test tells us that $\mathbf{F}$ is conservative.
37. (a) With $P(x, y) = x$ and $Q(x, y) = y$, note that P , Q , and their derivatives are continuous everywhere, and that $\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int x dx = \frac{1}{2}x^2 + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + h'(y) = y,$$

so that $h'(y) = y$. Integrating with respect to y gives $h(y) = \frac{1}{2}y^2 + K$ where K is a constant. So

$$\boxed{f(x, y) = \frac{1}{2}(x^2 + y^2) + K}.$$

- (c) By the Fundamental Theorem of Line Integrals, we have

$$\int_C (P dx + Q dy) = f(2, 5) - f(1, 3) = \left(\frac{1}{2}(2^2 + 5^2) + K \right) - \left(\frac{1}{2}(1^2 + 3^2) + K \right) = \boxed{\frac{19}{2}}.$$

38. (a) With $P(x, y) = 2xy$ and $Q(x, y) = x^2 + 1$, note that P , Q , and their derivatives are continuous everywhere, and that $\frac{\partial P}{\partial y} = 2x = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int 2xy dx = x^2y + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$x^2 + h'(y) = x^2 + 1,$$

so that $h'(y) = 1$. Integrating with respect to y gives $h(y) = y + K$ where K is a constant. So

$$\boxed{f(x, y) = x^2y + y + K}.$$

- (c) By the Fundamental Theorem of Line Integrals, we have

$$\int_C (P dx + Q dy) = f(-2, 3) - f(1, -4) = ((-2)^2 \cdot 3 + 3 + K) - (1^2 \cdot (-4) - 4 + K) = \boxed{23}.$$

39. (a) With $P(x, y) = x^2 + 3y$ and $Q(x, y) = 3x$, note that P , Q , and their derivatives are continuous everywhere, and that $\frac{\partial P}{\partial y} = 3 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (x^2 + 3y) dx = \frac{1}{3}x^3 + 3xy + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + 3x + h'(y) = 3x,$$

so that $h'(y) = 0$. Integrating with respect to y gives $h(y) = K$ where K is a constant. So

$$\boxed{f(x, y) = \frac{1}{3}x^3 + 3xy + K}.$$

(c) By the Fundamental Theorem of Line Integrals, we have

$$\begin{aligned}\int_C (P dx + Q dy) &= f(-3, 5) - f(1, 2) \\ &= \left(\frac{1}{3}(-3)^3 + 3 \cdot (-3) \cdot 5 + K \right) - \left(\frac{1}{3} \cdot 1^3 + 3 \cdot 1 \cdot 2 + K \right) = \boxed{-\frac{181}{3}}.\end{aligned}$$

40. (a) With $P(x, y) = 2x + y + 1$ and $Q(x, y) = x + 3y + 2$, note that P , Q , and their derivatives are continuous everywhere, and that $\frac{\partial P}{\partial y} = 1 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (2x + y + 1) dx = x^2 + xy + x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + x + 0 + h'(y) = x + 3y + 2,$$

so that $h'(y) = 3y + 2$. Integrate $h'(y)$ with respect to y :

$$\int h'(y) dy = \int (3y + 2) dy = \frac{3}{2}y^2 + 2y + K.$$

Therefore

$$f(x, y) = x^2 + xy + x + \frac{3}{2}y^2 + 2y + K = \boxed{x^2 + xy + \frac{3}{2}y^2 + x + 2y + K}.$$

(c) By the Fundamental Theorem of Line Integrals, we have

$$\begin{aligned}\int_C (P dx + Q dy) &= f(1, 2) - f(0, 0) \\ &= \left(1^2 + 1 \cdot 2 + \frac{3}{2} \cdot 2^2 + 1 + 2 \cdot 2 + K \right) - \left(0^2 + 0 \cdot 0 + \frac{3}{2} \cdot 0^2 + 0 + 2 \cdot 0 + K \right) \\ &= \boxed{14}.\end{aligned}$$

41. (a) With $P(x, y) = 4x^3 + 20xy^3 - 3y^4$ and $Q(x, y) = 30x^2y^2 - 12xy^3 + 5y^4$, note that P , Q , and their derivatives are continuous everywhere, and that $\frac{\partial P}{\partial y} = 60xy^2 - 12y^3 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (4x^3 + 20xy^3 - 3y^4) dx = x^4 + 10x^2y^3 - 3xy^4 + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + 30x^2y^2 - 12xy^3 + h'(y) = 30x^2y^2 - 12xy^3 + 5y^4,$$

so that $h'(y) = 5y^4$. Integrate $h'(y)$ with respect to y :

$$\int h'(y) dy = \int 5y^4 dy = y^5 + K.$$

Therefore

$$\boxed{f(x, y) = x^4 + 10x^2y^3 - 3xy^4 + y^5 + K}.$$

(c) By the Fundamental Theorem of Line Integrals, we have

$$\int_C (P dx + Q dy) = f(1, 1) - f(0, 0) = (1 + 10 - 3 + 1 + K) - (0 + 0 - 0 + 0 + K) = \boxed{9}.$$

42. (a) With $P(x, y) = 2yx^{-1}$ and $Q(x, y) = \ln(x^2)$, note that P , Q , and their derivatives are continuous for $x > 0$, and that $\frac{\partial P}{\partial y} = \frac{2}{x} = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path as long as the path stays to the right of the y -axis.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int \frac{2y}{x} dx = 2y \ln x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$2 \ln x + h'(y) = \ln(x^2) = 2 \ln x,$$

so that $h'(y) = 0$. Then $h(y) = K$, where K is a constant. Therefore

$$\boxed{f(x, y) = 2y \ln x + K}.$$

(c) By the Fundamental Theorem of Line Integrals, we have

$$\int_C (P dx + Q dy) = f(5, 5) - f(1, 1) = 10 \ln 5 - 2 \ln 1 = \boxed{10 \ln 5}.$$

43. (a) With $P(x, y) = 3x^2y^2$ and $Q(x, y) = 2x^3y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 6x^2y = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int 3x^2y^2 dx = x^3y^2 + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$2x^3y + h'(y) = 2x^3y,$$

so that $h'(y) = 0$. Then $h(y) = K$, where K is a constant. Therefore

$$\boxed{f(x, y) = x^3y^2 + K}.$$

44. (a) With $P(x, y) = 2x + y$ and $Q(x, y) = x - 2y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 1 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (2x + y) dx = x^2 + xy + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + x + h'(y) = x - 2y,$$

so that $h'(y) = -2y$. Integrating $h'(y)$ with respect to y gives

$$h(y) = \int h'(y) dy = \int (-2y) dy = -y^2 + K.$$

Therefore

$$\boxed{f(x, y) = x^2 + xy - y^2 + K}.$$

45. (a) With $P(x, y) = x + 3y$ and $Q(x, y) = 3x$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 3 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (x + 3y) dx = \frac{1}{2}x^2 + 3xy + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + 3x + h'(y) = 3x,$$

so that $h'(y) = 0$. Therefore $h(y) = K$, where K is a constant, and then

$$\boxed{f(x, y) = \frac{1}{2}x^2 + 3xy + K}.$$

46. (a) With $P(x, y) = 2x + y$ and $Q(x, y) = 2y + x$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 1 = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (2x + y) dx = x^2 + xy + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + x + h'(y) = 2y + x,$$

so that $h'(y) = 2y$. Integrating $h'(y)$ with respect to y gives

$$h(y) = \int h'(y) dy = \int 2y dy = y^2 + K.$$

Therefore

$$\boxed{f(x, y) = x^2 + xy + y^2 + K}.$$

47. (a) With $P(x, y) = 2xy - y^2$ and $Q(x, y) = x^2 - 2xy$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 2x - 2y = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (2xy - y^2) dx = x^2y - xy^2 + h(y)$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$x^2 - 2xy + h'(y) = x^2 - 2xy,$$

so that $h'(y) = 0$. Therefore $h(y) = K$, where K is a constant, and then

$$\boxed{f(x, y) = x^2y - xy^2 + K}.$$

48. (a) With $P(x, y) = y^2$ and $Q(x, y) = 2yx - e^y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 2y = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int y^2 dx = xy^2 + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$2xy + h'(y) = 2yx - e^y,$$

so that $h'(y) = -e^y$. Integrating $h'(y)$ with respect to y gives

$$h(y) = \int h'(y) dy = \int (-e^y) dy = -e^y + K.$$

Therefore

$$\boxed{f(x, y) = xy^2 - e^y + K}.$$

49. (a) With $P(x, y) = x^2 - x + y^2$ and $Q(x, y) = -(ye^y - 2xy) = 2xy - ye^y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 2y = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (x^2 - x + y^2) dx = \frac{1}{3}x^3 - \frac{1}{2}x^2 + xy^2 + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 - 0 + 2xy + h'(y) = 2xy - ye^y,$$

so that $h'(y) = -ye^y$. To integrate $h'(y)$, use integration by parts, with $u = y$ and $dv = -e^y dy$; then $du = dy$ and $v = -e^y$, so that

$$h(y) = \int (-ye^y) dy = -ye^y + \int e^y dy = e^y(1 - y) + K.$$

Therefore

$$\boxed{f(x, y) = \frac{1}{3}x^3 - \frac{1}{2}x^2 + xy^2 + e^y(1 - y) + K}.$$

50. (a) With $P(x, y) = 3x^2y + xy^2 + e^x$ and $Q(x, y) = x^3 + x^2y + \sin y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = 3x^2 + 2xy = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (3x^2y + xy^2 + e^x) dx = x^3y + \frac{1}{2}x^2y^2 + e^x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$x^3 + x^2y + 0 + h'(y) = x^3 + x^2y + \sin y,$$

so that $h'(y) = \sin y$. Integrating $h'(y)$ gives $h(y) = -\cos y + K$. Therefore

$$f(x, y) = x^3y + \frac{1}{2}x^2y^2 + e^x - \cos y + K.$$

51. (a) With $P(x, y) = y \cos x - 2 \sin y$ and $Q(x, y) = -(2x \cos y - \sin x) = \sin x - 2x \cos y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = \cos x - 2 \cos y = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (y \cos x - 2 \sin y) dx = y \sin x - 2x \sin y + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$\sin x - 2x \cos y + h'(y) = \sin x - 2x \cos y,$$

so that $h'(y) = 0$. It follows that $h(y) = K$, where K is a constant. Therefore

$$f(x, y) = y \sin x - 2x \sin y + K.$$

52. (a) With $P(x, y) = e^x \sin y + 2y \sin x$ and $Q(x, y) = e^x \cos y - 2 \cos x$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = e^x \cos y + 2 \sin x = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

- (b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (e^x \sin y + 2y \sin x) dx = e^x \sin y - 2y \cos x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$e^x \cos y - 2 \cos x + h'(y) = e^x \cos y - 2 \cos x,$$

so that $h'(y) = 0$. It follows that $h(y) = K$, where K is a constant. Therefore

$$f(x, y) = e^x \cos y - 2y \cos x + K.$$

53. (a) With $P(x, y) = 2x + y \cos x$ and $Q(x, y) = \sin x$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = \cos x = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (2x + y \cos x) dx = x^2 + y \sin x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$0 + \sin x + h'(y) = \sin x,$$

so that $h'(y) = 0$. It follows that $h(y) = K$, where K is a constant. Therefore

$$\boxed{f(x, y) = x^2 + y \sin x + K}.$$

54. (a) With $P(x, y) = \cos y - \cos x$ and $Q(x, y) = e^y - x \sin y$, note that P , Q , and their derivatives are continuous on the entire plane, and that $\frac{\partial P}{\partial y} = -\sin y = \frac{\partial Q}{\partial x}$. So the Conservative Vector Field Test tells us that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative, and then the Fundamental Theorem of Line Integrals ensures that $\int_C (P dx + Q dy)$ is independent of path on the entire plane.

(b) First integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int (\cos y - \cos x) dx = x \cos y - \sin x + h(y).$$

Differentiating this expression with respect to y and setting it equal to $Q(x, y)$ gives

$$-x \sin y - 0 + h'(y) = e^y - x \sin y,$$

so that $h'(y) = e^y$. It follows that $h(y) = e^y + K$, where K is a constant. Therefore

$$\boxed{f(x, y) = x \cos y - \sin x + e^y + K}.$$

Applications and Extensions

55. With $P(x, y) = -\frac{y}{x^2+y^2}$ and $Q(x, y) = \frac{x}{x^2+y^2}$, we have

$$\begin{aligned} \frac{\partial P}{\partial y} &= -\frac{(x^2 + y^2) \cdot 1 - y \cdot 2y}{(x^2 + y^2)^2} = \frac{-x^2 + y^2}{(x^2 + y^2)^2} \\ \frac{\partial Q}{\partial x} &= \frac{(x^2 + y^2) \cdot 1 - x \cdot 2x}{(x^2 + y^2)^2} = \frac{-x^2 + y^2}{(x^2 + y^2)^2}. \end{aligned}$$

Since these two are equal, it follows that $\mathbf{F} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ is conservative in any simply connected region where P , Q , $\frac{\partial P}{\partial y}$, and $\frac{\partial Q}{\partial x}$ are continuous. These functions fail to be continuous only where their denominators vanish; that happens only at $x = y = 0$, which is the origin. Since $a > 1$, all four points given are in the fourth quadrant, so that the origin does not lie in R . Since a rectangle is simply connected, and the four relevant functions are all continuous there, it follows that $\mathbf{F}$ is conservative in R . So by the Fundamental Theorem of Line Integrals, if C_1 and C_2 are two paths with the same endpoints lying completely in R , then $\int_{C_1} (P(x, y) dx + Q(x, y) dy) = \int_{C_2} (P(x, y) dx + Q(x, y) dy)$.

To find a potential function for $\mathbf{F}$, first integrate $P(x, y)$ with respect to x . Use the substitution $u = \frac{x}{y}$, so that $du = \frac{1}{y} dx$. Then

$$\int \left(-\frac{y}{x^2 + y^2} \right) dx = \int \left(-\frac{y}{(uy)^2 + y^2} \right) \cdot y du = - \int \frac{1}{u^2 + 1} du = -\tan^{-1} u + h(y) = -\tan^{-1} \frac{x}{y} + h(y).$$

Now differentiate this expression with respect to y and set it equal to $Q(x, y)$:

$$\begin{aligned}\frac{\partial}{\partial y} \left(-\tan^{-1} \frac{x}{y} + h(y) \right) &= -\frac{1}{\left(\frac{x}{y}\right)^2 + 1} \cdot \left(-\frac{x}{y^2} \right) + h'(y) \\ &= \frac{x}{y^2 \left(\left(\frac{x}{y}\right)^2 + 1 \right)} + h'(y) \\ &= \frac{x}{x^2 + y^2} + h'(y) \\ &= \frac{x}{x^2 + y^2}.\end{aligned}$$

It follows that $h'(y) = 0$, so that $h(y) = K$ is a constant. Therefore

$$\boxed{f(x, y) = -\tan^{-1} \frac{x}{y} + K}$$

is a potential function for $\mathbf{F}$.

56. Let $\mathbf{c} = x_0\mathbf{i} + y_0\mathbf{j} + z_0\mathbf{k}$. Then

$$\begin{aligned}\nabla(\mathbf{c} \cdot \mathbf{r}) &= \nabla(x_0x + y_0y + z_0z) \\ &= \frac{\partial}{\partial x}(x_0x + y_0y + z_0z)\mathbf{i} + \frac{\partial}{\partial y}(x_0x + y_0y + z_0z)\mathbf{j} + \frac{\partial}{\partial z}(x_0x + y_0y + z_0z)\mathbf{k} \\ &= x_0\mathbf{i} + y_0\mathbf{j} + z_0\mathbf{k} = \mathbf{c}.\end{aligned}$$

So if we set $f(x, y, z) = x_0x + y_0y + z_0z$, we have $\nabla f = \mathbf{c}$. Since the components of $\mathbf{c}$ are all continuous everywhere in space, as are its derivatives, it follows that $\mathbf{c}$ is conservative, so that if C is any closed piecewise smooth curve in space, $\int_C \mathbf{c} \cdot d\mathbf{r} = 0$ by the Value of a Line Integral over a Closed Curve.

57. (a) Since $\mathbf{F}(x, y)$ is directed towards the origin, a direction vector is $-x\mathbf{i} - y\mathbf{j}$. Normalizing gives a unit direction vector for $\mathbf{F}$ equal to

$$-\frac{x}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{y}{\sqrt{x^2 + y^2}}\mathbf{j}.$$

We are looking for a vector in the same direction, but with magnitude equal to $\frac{k}{x^2 + y^2}$; multiplying this by the above unit vector gives

$$\mathbf{F}(x, y) = \frac{k}{x^2 + y^2} \left(-\frac{x}{\sqrt{x^2 + y^2}}\mathbf{i} - \frac{y}{\sqrt{x^2 + y^2}}\mathbf{j} \right) = -\frac{kx}{(x^2 + y^2)^{3/2}}\mathbf{i} - \frac{ky}{(x^2 + y^2)^{3/2}}\mathbf{j}.$$

Note that $\mathbf{F}(x, y)$ is defined everywhere except at the origin. Let R be any simply connected open region not containing the origin. Then

$$P(x, y) = -\frac{kx}{(x^2 + y^2)^{3/2}}, \quad Q(x, y) = -\frac{ky}{(x^2 + y^2)^{3/2}}$$

are continuous on R , and

$$\begin{aligned}\frac{\partial P}{\partial y} &= -k \frac{(x^2 + y^2)^{3/2} \cdot 0 - x \cdot \frac{3}{2}(x^2 + y^2)^{1/2} \cdot 2y}{(x^2 + y^2)^3} = \frac{3kxy(x^2 + y^2)^{1/2}}{(x^2 + y^2)^3} = \frac{3kxy}{(x^2 + y^2)^{5/2}} \\ \frac{\partial Q}{\partial x} &= -k \frac{(x^2 + y^2)^{3/2} \cdot 0 - y \cdot \frac{3}{2}(x^2 + y^2)^{1/2} \cdot 2x}{(x^2 + y^2)^3} = \frac{3kxy(x^2 + y^2)^{1/2}}{(x^2 + y^2)^3} = \frac{3kxy}{(x^2 + y^2)^{5/2}}.\end{aligned}$$

Therefore both partials are continuous on R , and they are equal. It follows that $\mathbf{F}$ is conservative on R .

(b) To find a potential function for $\mathbf{F}$, first integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = - \int \frac{kx}{(x^2 + y^2)^{3/2}} dx = -k \int x(x^2 + y^2)^{-3/2} dx.$$

Use the substitution $u = x^2 + y^2$, so that $du = 2x dx$. Then we get

$$-k \int x(x^2 + y^2)^{-3/2} dx = -\frac{1}{2}k \int u^{-3/2} du = -\frac{1}{2}k \cdot (-2) \cdot u^{-1/2} + h(y) = k(x^2 + y^2)^{-1/2} + h(y).$$

Now differentiate this expression with respect to y and set it equal to $Q(x, y)$:

$$\begin{aligned} \frac{\partial}{\partial y} \left(k(x^2 + y^2)^{-1/2} + h(y) \right) &= -\frac{1}{2}k(x^2 + y^2)^{-3/2} \cdot 2y + h'(y) \\ &= -\frac{ky}{(x^2 + y^2)^{3/2}} + h'(y) \\ &= Q(x, y) = -\frac{ky}{(x^2 + y^2)^{3/2}}. \end{aligned}$$

Therefore $h'(y) = 0$, so that $h(y) = K$ is a constant. It follows that a potential function for $\mathbf{F}$ is

$$f(x, y) = k(x^2 + y^2)^{-1/2} + K = \boxed{\frac{k}{\sqrt{x^2 + y^2}} + K}.$$

58. Regard f as a function on the plane whose value at any point (x, y) is $f(x)$; similarly, regard g as a function on the plane whose value at any point (x, y) is $g(y)$. Then since f and g are differentiable, they are continuous everywhere on the plane. Further,

$$\frac{\partial f}{\partial y} = 0 = \frac{\partial g}{\partial x},$$

so that the derivatives are continuous everywhere, and are equal. Therefore $f(x)\mathbf{i} + g(y)\mathbf{j}$ is a conservative vector field, so that by the Value of a Line Integral over a Closed Curve, $\int_C [f(x) dx + g(y) dy] = 0$ if C is any circle in the plane.

Challenge Problem

59. Consider the function fg . We have by the product rule

$$\frac{\partial(fg)}{\partial x} = f(x, y) \frac{\partial g}{\partial x} + g(x, y) \frac{\partial f}{\partial x}, \quad \frac{\partial(fg)}{\partial y} = f(x, y) \frac{\partial g}{\partial y} + g(x, y) \frac{\partial f}{\partial y},$$

so that

$$\begin{aligned} \nabla(fg) &= \frac{\partial(fg)}{\partial x} \mathbf{i} + \frac{\partial(fg)}{\partial y} \mathbf{j} \\ &= \left(f(x, y) \frac{\partial g}{\partial x} + g(x, y) \frac{\partial f}{\partial x} \right) \mathbf{i} + \left(f(x, y) \frac{\partial g}{\partial y} + g(x, y) \frac{\partial f}{\partial y} \right) \mathbf{j} \\ &= \left(f(x, y) \frac{\partial g}{\partial x} \mathbf{i} + f(x, y) \frac{\partial g}{\partial y} \mathbf{j} \right) + \left(g(x, y) \frac{\partial f}{\partial x} \mathbf{i} + g(x, y) \frac{\partial f}{\partial y} \mathbf{j} \right) \\ &= f(x, y) \left(\frac{\partial g}{\partial x} \mathbf{i} + \frac{\partial g}{\partial y} \mathbf{j} \right) + g(x, y) \left(\frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} \right) \\ &= f \nabla g + g \nabla f. \end{aligned}$$

Therefore $f \nabla g + g \nabla f$ is a conservative vector field on R , since it is equal to $\nabla(fg)$. So if C is any piecewise smooth curve in R from A to B , the Fundamental Theorem of Line Integrals gives

$$\int_C (f \nabla g + g \nabla f) \cdot d\mathbf{r} = (fg)(B) - (fg)(A) = f(B)g(B) - f(A)g(A),$$

so that

$$\int_C f \nabla g \cdot d\mathbf{r} = f(B)g(B) - f(A)g(A) - \int_C g \nabla f \cdot d\mathbf{r}.$$

15.4: An Application of Line Integrals: Work

Concepts and Vocabulary

1. Work is the *energy* transferred to or from an object by a force acting on the object. See the opening sentences of this section.
2. True. See the definition of Work.
3. False. The work done is the change in potential energy from B to A . See the discussion just prior to the Law of Conservation of Energy.
4. (d) is correct. See Work on a Closed Path.
5. Kinetic energy K is the energy of *motion*. Potential energy U is the energy of *position*.
6. False. The Law of Conservation of Energy says that the *sum* of the potential and kinetic energies of an object is a constant (not necessarily zero).

Skill Building

7. Along the given curve $\mathbf{r}$ we have $x(t) = t$ and $y(t) = t^2$, so that $\mathbf{F} = t^2\mathbf{i} + t\mathbf{j}$. Then the work done is

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (t^2\mathbf{i} + t\mathbf{j}) \cdot (\mathbf{i} + 2t\mathbf{j}) dt = \int_0^1 3t^2 dt = [t^3]_0^1 = \boxed{1}.$$

8. Along the given curve $\mathbf{r}$ we have $x(t) = t$ and $y(t) = t^2$, so that $\mathbf{F} = t \cdot t^2\mathbf{i} + (t^2)^2\mathbf{j} = t^3\mathbf{i} + t^4\mathbf{j}$. Then the work done is

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (t^3\mathbf{i} + t^4\mathbf{j}) \cdot (\mathbf{i} + 2t\mathbf{j}) dt = \int_0^1 (t^3 + 2t^5) dt = \left[\frac{1}{4}t^4 + \frac{1}{3}t^6 \right]_0^1 = \boxed{\frac{7}{12}}.$$

9. Along the given curve $\mathbf{r}$ we have $x(t) = 3 \cos t$ and $y(t) = 2 \sin t$, so that

$$\mathbf{F} = (3 \cos t - 4 \sin t)\mathbf{i} + (3 \cos t)(2 \sin t)\mathbf{j} = (3 \cos t - 4 \sin t)\mathbf{i} + 6 \sin t \cos t\mathbf{j}.$$

Then the work done is

$$\begin{aligned} W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\ &= \int_0^{\pi/2} ((3 \cos t - 4 \sin t)\mathbf{i} + 6 \sin t \cos t\mathbf{j}) \cdot (-3 \sin t\mathbf{i} + 2 \cos t\mathbf{j}) dt \\ &= \int_0^{\pi/2} (-9 \sin t \cos t + 12 \sin^2 t + 12 \sin t \cos^2 t) dt \\ &= \int_0^{\pi/2} (-9 \sin t \cos t + 6(1 - \cos(2t)) + 12 \sin t \cos^2 t) dt \\ &= \left[-\frac{9}{2} \sin^2 t + 6 \left(t - \frac{1}{2} \sin(2t) \right) - 4 \cos^3 t \right]_0^{\pi/2} \\ &= \left(-\frac{9}{2} + 6 \left(\frac{\pi}{2} - 0 \right) - 0 \right) - (0 + 6 \cdot 0 - 4 \cdot 1) \\ &= \boxed{3\pi - \frac{1}{2}}. \end{aligned}$$

10. With $P(x, y) = x$ and $Q(x, y) = y$, we see that P , Q , and their derivatives are continuous everywhere, and that $\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x}$. Therefore this is a conservative field, and since the path is closed, the integral along the path is $\boxed{0}$.

11. With $P(x, y) = x^2y$ and $Q(x, y) = x^2 - y^2$, on the curve $y = 2x^2$ we have $dy = 4x dx$. Then

$$\begin{aligned} \int_{(0,0)}^{(1,2)} (P(x, y) dx + Q(x, y) dy) &= \int_0^1 (x^2 \cdot 2x^2 + (x^2 - (2x^2)^2) \cdot 4x) dx \\ &= \int_0^1 (-16x^5 + 2x^4 + 4x^3) dx \\ &= \left[-\frac{8}{3}x^6 + \frac{2}{5}x^5 + x^4 \right]_0^1 \\ &= \boxed{-\frac{19}{15}}. \end{aligned}$$

12. With $P(x, y) = y \sin x$ and $Q(x, y) = -x \cos y$, on the curve $y = x$ we have $dy = dx$. Then

$$\int_{(0,0)}^{(1,1)} (P(x, y) dx + Q(x, y) dy) = \int_0^1 (x \sin x - x \cos x) dx = \int_0^1 x(\sin x - \cos x) dx.$$

Use integration by parts, with $u = x$ and $dv = (\sin x - \cos x) dx$; then $du = dx$ and $v = -(\cos x + \sin x)$, so that

$$\begin{aligned} \int_0^1 x(\sin x - \cos x) dx &= [-x(\cos x + \sin x)]_0^1 + \int_0^1 (\cos x + \sin x) dx \\ &= -1(\cos 1 + \sin 1) + [\sin x - \cos x]_0^1 \\ &= (-\cos 1 - \sin 1) + (\sin 1 - \cos 1 + 1) = \boxed{1 - 2 \cos 1}. \end{aligned}$$

13. Parametrize the upper half of the circle as $x(t) = \cos t$, $y(t) = \sin t$ for $0 \leq t \leq \pi$. Then $dx = -\sin t dt$ and $dy = \cos t dt$. With $P(x, y) = y - x^2$ and $Q(x, y) = x$, we get for the work

$$\begin{aligned} \int_C (P(x, y) dx + Q(x, y) dy) &= \int_0^\pi ((\sin t - \cos^2 t) \cdot (-\sin t) + (\cos t) \cdot \cos t) dt \\ &= \int_0^\pi (-\sin^2 t + \cos^2 t \sin t + \cos^2 t) dt \\ &= \int_0^\pi (\cos(2t) + \cos^2 t \sin t) dt \\ &= \left[\frac{1}{2} \sin(2t) - \frac{1}{3} \cos^3 t \right]_0^\pi \\ &= \boxed{\frac{2}{3}}. \end{aligned}$$

14. For the first portion of the path, parametrize by $x = 1$, $y = t$ for $0 \leq t \leq 1$. Then the work is

$$\int_C (P(x, y) dx + Q(x, y) dy) = \int_0^1 ((t-1) \cdot 0 + 1 \cdot 1) dt = \int_0^1 1 dt = 1.$$

Parametrize the second portion of the path by $x = 1 - 2t$, $y = 1$ for $0 \leq t \leq 1$. Then the work is

$$\begin{aligned} \int_C (P(x, y) dx + Q(x, y) dy) &= \int_0^1 ((1 - (1 - 2t)^2) \cdot (-2) + (1 - 2t) \cdot 0) dt \\ &= \int_0^1 (8t^2 - 8t) dt = \left[\frac{8}{3}t^3 - 4t^2 \right]_0^1 = -\frac{4}{3}. \end{aligned}$$

Parametrize the third portion of the path by $x = -1$, $y = 1 - t$ for $0 \leq t \leq 1$. Then the work is

$$\int_C (P(x, y) dx + Q(x, y) dy) = \int_0^1 ((1 - t - (-1)^2) \cdot 0 - 1 \cdot (-1)) dt = \int_0^1 1 dt = 1.$$

The total work is the sum of the work along each piece of the path, so it is $1 - \frac{4}{3} + 1 = \boxed{\frac{2}{3}}$.

15. Along the given curve $\mathbf{r}$ we have $x(t) = a \cos t$ and $y(t) = b \sin t$, so that

$$\mathbf{F} = (b \sin t)^3 \mathbf{i} + (a \cos t)^3 \mathbf{j} = b^3 \sin^3 t \mathbf{i} + a^3 \cos^3 t \mathbf{j}.$$

Then the work done is

$$\begin{aligned} W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\ &= \int_0^{2\pi} (b^3 \sin^3 t \mathbf{i} + a^3 \cos^3 t \mathbf{j}) \cdot (-a \sin t \mathbf{i} + b \cos t \mathbf{j}) dt \\ &= \int_0^{2\pi} (-ab^3 \sin^4 t + ba^3 \cos^4 t) dt. \end{aligned}$$

Now use numbers 90 and 91 in the Endnotes to evaluate these integrals.

$$\begin{aligned} \int_0^{2\pi} \sin^4 t dt &= \left[-\frac{1}{4} \sin^3 t \cos t \right]_0^{2\pi} + \frac{3}{4} \int_0^{2\pi} \sin^2 t dt \\ &= \frac{3}{4} \int_0^{2\pi} \sin^2 t dt \\ &= \frac{3}{4} \int_0^{2\pi} \frac{1}{2} (1 - \cos(2t)) dt \\ &= \frac{3}{4} \left[\frac{1}{2} t - \sin(2t) \right]_0^{2\pi} \\ &= \frac{3}{4} \pi, \end{aligned}$$

and

$$\begin{aligned} \int_0^{2\pi} \cos^4 t dt &= \left[\frac{1}{4} \cos^3 t \sin t \right]_0^{2\pi} + \frac{3}{4} \int_0^{2\pi} \cos^2 t dt \\ &= \frac{3}{4} \int_0^{2\pi} \cos^2 t dt \\ &= \frac{3}{4} \int_0^{2\pi} \frac{1}{2} (1 + \cos(2t)) dt \\ &= \frac{3}{4} \left[\frac{1}{2} t + \sin(2t) \right]_0^{2\pi} \\ &= \frac{3}{4} \pi, \end{aligned}$$

So the work performed is

$$\int_0^{2\pi} (-ab^3 \sin^4 t + ba^3 \cos^4 t) dt = -ab^3 \cdot \frac{3}{4} \pi + ba^3 \cdot \frac{3}{4} \pi = \boxed{\frac{3}{4} ab \pi (a^2 - b^2)}.$$

16. Parametrize the upper half of the ellipse by $x(t) = a \cos t$ and $y(t) = b \sin t$ for $0 \leq t \leq \pi$. Then

$$\mathbf{F} = -(b \sin t)^2 \mathbf{i} + (a \cos t)^2 \mathbf{j} = -b^2 \sin^2 t \mathbf{i} + a^2 \cos^2 t \mathbf{j}.$$

Then the work done is

$$\begin{aligned} W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\ &= \int_0^{2\pi} (-b^2 \sin^2 t \mathbf{i} + a^2 \cos^2 t \mathbf{j}) \cdot (-a \sin t \mathbf{i} + b \cos t \mathbf{j}) dt \\ &= \int_0^{2\pi} (ab^2 \sin^3 t + ba^2 \cos^3 t) dt. \end{aligned}$$

Now use numbers 90 and 91 in the Endnotes to evaluate these integrals.

$$\begin{aligned} \int_0^\pi \sin^3 t dt &= \left[-\frac{1}{3} \sin^3 t \cos t \right]_0^\pi + \frac{2}{3} \int_0^\pi \sin t dt \\ &= \frac{2}{3} \int_0^\pi \sin t dt \\ &= \frac{2}{3} [-\cos t]_0^\pi = \frac{4}{3} \end{aligned}$$

and

$$\begin{aligned} \int_0^\pi \cos^3 t dt &= \left[\frac{1}{3} \cos^2 t \sin t \right]_0^\pi + \frac{2}{3} \int_0^\pi \cos t dt \\ &= \frac{2}{3} \int_0^\pi \cos t dt \\ &= \frac{2}{3} [\sin t]_0^\pi = 0. \end{aligned}$$

So the work performed is

$$\int_0^{2\pi} (ab^2 \sin^3 t + ba^2 \cos^3 t) dt = ab^2 \cdot \frac{4}{3} + ba^2 \cdot 0 = \boxed{\frac{4}{3} ab^2}.$$

17. Since $P(x, y) = 3x$ and $Q(x, y) = 2y$ are continuous everywhere in the plane, their derivatives are as well, and

$$\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x},$$

it follows that $\mathbf{F}$ is conservative. Since the path pictured is a closed path, the work done is $\boxed{0}$.

18. With $P(x, y) = 2xy$ and $Q(x, y) = xy^2$, we have

$$\frac{\partial P}{\partial y} = 2x \neq y^2 = \frac{\partial Q}{\partial x},$$

so that $\mathbf{F}$ is not conservative. Therefore we must compute the integrals. Parametrize the three portions of the path as follows:

$$\begin{aligned} C_1 &: (0, 0) \text{ to } (1, 1), \quad \mathbf{r}_1(t) = t \mathbf{i} + t \mathbf{j}, \quad 0 \leq t \leq 1 \\ C_2 &: (1, 1) \text{ to } (-1, 1), \quad \mathbf{r}_2(t) = (1 - 2t) \mathbf{i} + \mathbf{j}, \quad 0 \leq t \leq 1 \\ C_3 &: (-1, 1) \text{ to } (0, 0), \quad \mathbf{r}_3(t) = (-1 + t) \mathbf{i} + (1 - t) \mathbf{j}, \quad 0 \leq t \leq 1. \end{aligned}$$

Then the work is

$$\begin{aligned}
 W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\
 &= \int_{C_1} \mathbf{F} \cdot d\mathbf{r}_1 + \int_{C_2} \mathbf{F} \cdot d\mathbf{r}_2 + \int_{C_3} \mathbf{F} \cdot d\mathbf{r}_3 \\
 &= \int_0^1 (2t \cdot t \mathbf{i} + t \cdot t^2 \mathbf{j}) \cdot (\mathbf{i} + \mathbf{j}) \\
 &\quad + \int_0^1 (2 \cdot (1 - 2t) \cdot 1 \mathbf{i} + (1 - 2t) \cdot 1^2 \mathbf{j}) \cdot (-2\mathbf{i}) \\
 &\quad + \int_0^1 (2(-1 + t)(1 - t)\mathbf{i} + (-1 + t)(1 - t)^2 \mathbf{j}) \cdot (\mathbf{i} - \mathbf{j}) \\
 &= \int_0^1 (2t^2 + t^3) dt + \int_0^1 (-4(1 - 2t)) dt + \int_0^1 (2(-1 + t)(1 - t) - (-1 + t)(1 - t)^2) dt \\
 &= \int_0^1 (2t^2 + t^3) dt + \int_0^1 (8t - 4) dt + \int_0^1 (-t^3 + t^2 + t - 1) dt \\
 &= \left[\frac{2}{3}t^3 + \frac{1}{4}t^4 \right]_0^1 + [4t^2 - 4t]_0^1 + \left[-\frac{1}{4}t^4 + \frac{1}{3}t^3 + \frac{1}{2}t^2 - t \right]_0^1 \\
 &= \frac{2}{3} + \frac{1}{4} + 4 - 4 - \frac{1}{4} + \frac{1}{3} + \frac{1}{2} - 1 \\
 &= \boxed{\frac{1}{2}}.
 \end{aligned}$$

19. Since $P(x, y) = e^x y$ and $Q(x, y) = e^x$ are continuous everywhere in the plane, their derivatives are as well, and

$$\frac{\partial P}{\partial y} = e^x = \frac{\partial Q}{\partial x},$$

it follows that $\mathbf{F}$ is conservative. To find a potential function, integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int e^x y dx = e^x y + h(y).$$

Now differentiate this expression with respect to y and set it equal to $Q(x, y)$:

$$e^x + h'(y) = e^x,$$

so that $h'(y) = 0$ and therefore $h(y) = K$ is a constant. So

$$f(x, y) = e^x y + K$$

is a potential function. So the integral, which is the work performed, is

$$f(1, 0) - f(-1, -1) = (e^1 \cdot 0 + K) - (e^{-1} \cdot (-1) + K) = \boxed{\frac{1}{e}}.$$

20. Since $P(x, y) = e^x$ and $Q(x, y) = 5y$ are continuous everywhere in the plane, their derivatives are as well, and

$$\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x},$$

it follows that $\mathbf{F}$ is conservative. To find a potential function, integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int e^x dx = e^x + h(y).$$

Now differentiate this expression with respect to y and set it equal to $Q(x, y)$:

$$0 + h'(y) = 5y,$$

so that $h'(y) = 5y$ and therefore $h(y) = \frac{5}{2}y^2 + K$. So

$$f(x, y) = e^x + \frac{5}{2}y^2 + K$$

is a potential function. So the integral, which is the work performed, is

$$f(1, 0) - f(-1, 2) = \left(e^1 + \frac{5}{2} \cdot 0^2 + K \right) - \left(e^{-1} + \frac{5}{2} \cdot 2^2 + K \right) = \boxed{e - \frac{1}{e} - 10}.$$

Applications and Extensions

21. To see that $\mathbf{F}$ is not conservative, note that

$$\frac{\partial P}{\partial y} = \frac{\partial}{\partial y}(y) = 1 \neq \frac{\partial Q}{\partial x} = \frac{\partial}{\partial x}(-x) = -1.$$

Since these partials are unequal, $\mathbf{F}$ is not conservative.

Now consider the path C given by $\mathbf{r}(t) = t\mathbf{i} + t\mathbf{j}$ for $0 \leq t \leq 1$ from $(0, 0)$ to $(1, 1)$. The integral along this path is

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (t\mathbf{i} - t\mathbf{j}) \cdot (\mathbf{i} + \mathbf{j}) dt = \int_0^1 0 dt = \boxed{0}.$$

For the other path, let C_1 be given by $\mathbf{r}_1(t) = t\mathbf{i}$ for $0 \leq t \leq 1$ from $(0, 0)$ to $(1, 0)$, and then C_2 be given by $\mathbf{r}_2(t) = \mathbf{i} + t\mathbf{j}$ for $0 \leq t \leq 1$ from $(1, 0)$ to $(1, 1)$. The integral along this path is

$$\int_{C_1 C_2} \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot d\mathbf{r}_1 + \int_{C_2} \mathbf{F} \cdot d\mathbf{r}_2 = \int_0^1 (-t\mathbf{j}) \cdot \mathbf{i} dt + \int_0^1 (t\mathbf{i} - \mathbf{j}) \cdot \mathbf{j} dt = \int_0^1 0 dt + \int_0^1 (-1) dt = \boxed{-1}.$$

22. With the given parametrization, we have

$$\mathbf{F} = x^2\mathbf{i} + y\mathbf{j} = t^2\mathbf{i} + t^2\mathbf{j},$$

so the work performed is

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^3 (t^2\mathbf{i} + t^2\mathbf{j}) \cdot (\mathbf{i} + 2t\mathbf{j}) dt = \int_0^3 (t^2 + 2t^3) dt = \left[\frac{1}{3}t^3 + \frac{1}{2}t^4 \right]_0^3 = \boxed{\frac{99}{2}}.$$

23. Since $P(x, y) = \cos x$ and $Q(x, y) = \sin y$ are continuous everywhere, as are their derivatives, and also

$$\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x},$$

the field is conservative. To find a potential function, integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int \cos x dx = \sin x + h(y).$$

Now differentiate this expression with respect to y and set equal to $Q(x, y)$:

$$0 + h'(y) = \sin y.$$

Therefore $h'(y) = \sin y$, so that $h(y) = -\cos y + K$. It follows that a potential function is (choosing $K = 0$)

$$f(x, y) = \sin x - \cos y.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = f(\pi, \sqrt{\pi}) - f(0, 0) = (\sin \pi - \cos \sqrt{\pi}) - (0 - 1) = \boxed{1 - \cos \sqrt{\pi}}.$$

24. $\mathbf{F}$ has magnitude 3 in the direction of $\mathbf{i} + \mathbf{j}$, so

$$\mathbf{F} = \frac{3}{\sqrt{2}}\mathbf{i} + \frac{3}{\sqrt{2}}\mathbf{j}.$$

Since $P(x, y) = \frac{3}{\sqrt{2}}$ and $Q(x, y) = \frac{3}{\sqrt{2}}$ are continuous everywhere, as are their derivatives, and also

$$\frac{\partial P}{\partial y} = 0 = \frac{\partial Q}{\partial x},$$

the field is conservative. To find a potential function, integrate $P(x, y)$ with respect to x :

$$\int P(x, y) dx = \int \frac{3}{\sqrt{2}} dx = \frac{3}{\sqrt{2}}x + h(y).$$

Now differentiate this expression with respect to y and set equal to $Q(x, y)$:

$$0 + h'(y) = \frac{3}{\sqrt{2}}.$$

Therefore $h'(y) = \frac{3}{\sqrt{2}}$, so that $h(y) = \frac{3}{\sqrt{2}}y + K$. It follows that a potential function is (choosing $K = 0$)

$$f(x, y) = \frac{3}{\sqrt{2}}x + \frac{3}{\sqrt{2}}y.$$

Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = f(2a, 0) - f(0, 0) = \frac{3}{\sqrt{2}}(2a + 0) - \frac{3}{\sqrt{2}}(0 + 0) = \boxed{3a\sqrt{2}}.$$

25. The velocity is

$$\mathbf{v}(t) = \mathbf{r}'(t) = 64\sqrt{3}\mathbf{i} + (64 - 32t)\mathbf{j},$$

so that the speed of the object is $s(t) = \|\mathbf{v}(t)\|$.

$$s(t) = \|\mathbf{v}(t)\| = \sqrt{(64\sqrt{3})^2 + (64 - 32t)^2} = \sqrt{1024t^2 - 4096t + 16384} = 32\sqrt{t^2 - 4t + 16}.$$

Then $\mathbf{F}$ has direction $-\mathbf{v}(t) = -64\sqrt{3}\mathbf{i} + (32t - 64)\mathbf{j}$ and magnitude $ks(t) = k\|\mathbf{v}(t)\|$ for some constant of proportionality $k > 0$. So

$$\mathbf{F} = ks(t) \frac{-\mathbf{v}(t)}{\|\mathbf{v}(t)\|} = \frac{k\|\mathbf{v}(t)\|}{\|\mathbf{v}(t)\|} (-\mathbf{v}(t)) = -k\mathbf{v}(t).$$

for some constant $k > 0$. Then the work done by the force is

$$\begin{aligned} W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\ &= \int_0^4 (-k\mathbf{v}(t)) \cdot \mathbf{v}(t) dt \\ &= -k \int_0^4 \|\mathbf{v}(t)\|^2 dt \\ &= -k \int_0^4 s(t)^2 dt \\ &= -1024k \int_0^4 (t^2 - 4t + 16) dt \\ &= -1024k \left[\frac{1}{3}t^3 - 2t^2 + 16t \right]_0^4 \\ &= \boxed{-\frac{163840}{3}k}. \end{aligned}$$

26. We have $P(x, y) = y^2 + 1$ and $Q(x, y) = x + y$. Further, on the given curve, using the product rule gives $dy = (a(1 - x) - ax) dx = (a - 2ax) dx$. Then the work done is

$$\begin{aligned}
 W &= \int_C (P(x, y) dx + Q(x, y) dy) \\
 &= \int_0^1 ((ax(1 - x))^2 + 1) \cdot 1 + (x + ax(1 - x)) \cdot (a - 2ax) dx \\
 &= \int_0^1 (a^2x^2 - 2a^2x^3 + a^2x^4 + 1 + ((a + 1)x - ax^2)(a - 2ax)) dx \\
 &= \int_0^1 (a^2x^2 - 2a^2x^3 + a^2x^4 + 1 + a(a + 1)x - 2a(a + 1)x^2 - a^2x^2 + 2a^2x^3) dx \\
 &= \left[\frac{1}{3}a^2x^3 - \frac{1}{2}a^2x^4 + \frac{1}{5}a^2x^5 + x + \frac{1}{2}a(a + 1)x^2 - \frac{2}{3}a(a + 1)x^3 - \frac{1}{3}a^2x^3 + \frac{1}{2}a^2x^4 \right]_0^1 \\
 &= \frac{1}{3}a^2 - \frac{1}{2}a^2 + \frac{1}{5}a^2 + 1 + \frac{1}{2}a(a + 1) - \frac{2}{3}a(a + 1) - \frac{1}{3}a^2 + \frac{1}{2}a^2 \\
 &= \frac{1}{30}a^2 - \frac{1}{6}a + 1.
 \end{aligned}$$

We want to find the value of a that minimizes the work, so taking the derivative of this quadratic with respect to a gives

$$\frac{1}{15}a - \frac{1}{6} = 0,$$

so that $a = \boxed{\frac{5}{2}}$.

27. Exercise 57 in Section 15.3 shows that the vector field

$$-\mathbf{F} = -\frac{x}{(x^2 + y^2)^{3/2}} - \frac{y}{(x^2 + y^2)^{3/2}}$$

is conservative, with potential function $\frac{1}{\sqrt{x^2 + y^2}} + K$. It follows that $\mathbf{F}$ is also conservative, since

$$\frac{\partial P}{\partial y} = -\frac{\partial(-P)}{\partial y} = -\frac{\partial(-Q)}{\partial x} = \frac{\partial Q}{\partial x},$$

and that its potential function is

$$f(x, y) = -\frac{1}{\sqrt{x^2 + y^2}} + K.$$

Therefore the work done between the two given points is

$$W = f(-1, 2) - f(1, 0) = -\frac{1}{\sqrt{(-1)^2 + 2^2}} - \left(-\frac{1}{\sqrt{1^2 + 0^2}} \right) = \boxed{1 - \frac{\sqrt{5}}{5}}.$$

28. Along the given helix, the vector field is

$$\mathbf{F} = x \mathbf{i} + y \mathbf{j} + \mathbf{k} = \sin t \mathbf{i} + \cos t \mathbf{j} + \mathbf{k}.$$

Then the work done is

$$\begin{aligned}
 W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\
 &= \int_0^\pi (\sin t \mathbf{i} + \cos t \mathbf{j} + \mathbf{k}) \cdot (\cos t \mathbf{i} - \sin t \mathbf{j} + \mathbf{k}) dt \\
 &= \int_0^\pi (\sin t \cos t - \sin t \cos t + 1) dt \\
 &= [t]_0^\pi = \boxed{\pi}.
 \end{aligned}$$

29. Along the given helix, the vector field is

$$\mathbf{F} = x^2 \mathbf{i} + y^2 \mathbf{j} + z^2 \mathbf{k} = (2 \cos t)^2 \mathbf{i} + (2 \sin t)^2 \mathbf{j} + (2t)^2 \mathbf{k} = 4 \cos^2 t \mathbf{i} + 4 \sin^2 t \mathbf{j} + 4t^2 \mathbf{k}.$$

Then the work done is

$$\begin{aligned} W &= \int_C \mathbf{F} \cdot d\mathbf{r} \\ &= \int_0^\pi (4 \cos^2 t \mathbf{i} + 4 \sin^2 t \mathbf{j} + 4t^2 \mathbf{k}) \cdot (-2 \sin t \mathbf{i} + 2 \cos t \mathbf{j} + 2 \mathbf{k}) dt \\ &= \int_0^\pi (-8 \cos^2 t \sin t + 8 \sin^2 t \cos t + 8t^2) dt \\ &= 8 \int_0^\pi (\sin^2 t \cos t - \cos^2 t \sin t + t^2) dt \\ &= 8 \left[\frac{1}{3} \sin^3 t + \frac{1}{3} \cos^3 t + \frac{1}{3} t^3 \right]_0^\pi \\ &= 8 \left(\left(0 - \frac{1}{3} + \frac{\pi^3}{3} \right) - \left(0 + \frac{1}{3} + 0 \right) \right) \\ &= 8 \left(\frac{\pi^3}{3} - \frac{2}{3} \right) = \boxed{\frac{8}{3}(\pi^3 - 2)}. \end{aligned}$$

30. For any piecewise smooth curve $C : \mathbf{r} = x(t) \mathbf{i} + y(t) \mathbf{j} + z(t) \mathbf{k}$, the work expended by gravity along that path is

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_C mg \mathbf{k} \cdot (dx \mathbf{i} + dy \mathbf{j} + dz \mathbf{k}) = \int_C mg dz = \int_{z_1}^{z_2} mg dz = mg(z_2 - z_1).$$

31. (a) The direction of the path at any given point is $\mathbf{r}'$, so saying that $\mathbf{F}$ is orthogonal to the path at each point is the same as saying that $\mathbf{F} \cdot \mathbf{r}' = 0$. Therefore the work done is

$$W = \int_C \mathbf{F} \cdot \mathbf{r}' = \int_C 0 dt = 0.$$

(b) Answers will vary.

32. Suppose that C_1 and C_2 are two paths in S from A to B . Consider the piecewise smooth path C consisting of C_1 followed by $-C_2$ (that is, C_1 followed by C_2 in the opposite direction). Then

$$0 = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot d\mathbf{r} + \int_{-C_2} \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot d\mathbf{r} - \int_{C_2} \mathbf{F} \cdot d\mathbf{r}.$$

Rearranging this equation gives

$$\int_{C_1} \mathbf{F} \cdot d\mathbf{r} = \int_{C_2} \mathbf{F} \cdot d\mathbf{r}.$$

Challenge Problem

33. (a) From Example 4 in Section 15.1, the gravitational field is defined by

$$\mathbf{F}(x, y, z) = -\frac{GmM}{x^2 + y^2 + z^2} \mathbf{u},$$

where an object of mass M is centered at the origin and an object of mass m is centered at (x, y, z) . Here G is the universal gravitational constant and $\mathbf{u}$ is a unit vector in the direction

of $\langle x, y, z \rangle$. Writing $\mathbf{r} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ and $r = \|\mathbf{r}\| = \sqrt{x^2 + y^2 + z^2}$, we can rewrite the above formula as

$$\mathbf{F}(x, y, z) = -\frac{GmM}{r^2} \cdot \frac{\mathbf{r}}{\|\mathbf{r}\|} = -\frac{GmM}{r^3} \mathbf{r}.$$

Problem 15.1.22 shows that $\mathbf{F}$ is conservative, with potential function $U(r) = -\frac{GmM}{r}$. The equation for $\mathbf{F}$ shows that the gravitational force acts arbitrarily far away from the object with mass M , but with a magnitude approaching zero. Since the kinetic energy is given by

$$K = \frac{m}{2} \|\mathbf{r}'(t)\|^2 = \frac{m}{2} \|\mathbf{v}\|^2,$$

and escape velocity is the velocity at which the object just escapes the gravitational force, we see that escape velocity is the velocity for which the kinetic energy approaches but never reaches zero as the object gets further away. But as the object gets further away, we also have

$$\lim_{r \rightarrow \infty} U(r) = \lim_{r \rightarrow \infty} \left(-\frac{GmM}{r} \right) = 0.$$

So both the kinetic and potential energies approach zero as the object gets further and further away when launched at escape velocity.

Now let $K(t)$ and $U(t)$ be the kinetic and potential energies at any time t , with $t = 0$ corresponding to launch. By Conservation of Energy, the sum of the kinetic and potential energies at any pair of times is the same, so that $K(0) + U(0) = \lim_{t \rightarrow \infty} (K(t) + U(t)) = 0$. If the initial speed is $\|\mathbf{v}_0\| = s$, then $K(0) = \frac{1}{2}ms^2$ by the discussion of Work and Kinetic Energy in the text. Also, by the discussion of Work and Potential Energy in the text, the initial potential energy is $U(0) = -\frac{GmM}{R}$, since the initial distance of the object is R . So we get

$$K(0) + U(0) = \frac{1}{2}ms^2 - \frac{GmM}{R} = 0.$$

Divide through by m and rearrange to get

$$\frac{1}{2}s^2 = \frac{GM}{R}, \text{ or } s = \sqrt{\frac{2GM}{R}}$$

- (b) $\sqrt{\frac{2GM}{R}} \approx 11173 \text{ m/s}$ $\approx 11.173 \text{ km/s}$.
- (c) $\sqrt{\frac{2GM}{R}} \approx 5019 \text{ m/s}$ $\approx 5.019 \text{ km/s}$.
- (d) $\sqrt{\frac{2GM}{R}} \approx 617589 \text{ m/s}$ $\approx 617.589 \text{ km/s}$.

15.5: Green's Theorem

Concepts and Vocabulary

- Green's Theorem relates the value of a *line* integral along a simple closed piecewise smooth curve C to the value of a *double* integral over the simply connected closed region R enclosed by C .
- $\oint_C (P(x, y) dx + Q(x, y) dy) = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy$.
- False. The direction of traversal is counterclockwise.
- It equals the *area* of R . See the discussion in Objective 2.

Skill Building

5. Here $P(x, y) = y$ and $Q(x, y) = 0$, so that

$$\begin{aligned}\oint_C y \, dx &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \iint_R (-1) \, dx \, dy = \int_0^3 \int_0^4 (-1) \, dx \, dy \\ &= \int_0^3 [-x]_0^4 \, dy = \int_0^3 (-4) \, dy = [-4y]_0^3 = \boxed{-12}.\end{aligned}$$

6. Here $P(x, y) = 0$ and $Q(x, y) = x$, so that

$$\oint_C x \, dy = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \iint_R 1 \, dx \, dy = \int_0^3 \int_0^4 1 \, dx \, dy = \int_0^3 [x]_0^4 \, dy = \int_0^3 4 \, dy = \boxed{12}.$$

7. Here $P(x, y) = xy$ and $Q(x, y) = x + y$, so that

$$\begin{aligned}\oint_C (xy \, dx + (x + y) \, dy) &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \iint_R (1 - x) \, dx \, dy = \int_0^3 \int_0^4 (1 - x) \, dx \, dy \\ &= \int_0^3 \left[x - \frac{1}{2}x^2 \right]_0^4 \, dy = \int_0^3 (-4) \, dy = \boxed{-12}.\end{aligned}$$

8. Here $P(x, y) = 3y$ and $Q(x, y) = -2x$, so that

$$\begin{aligned}\oint_C (3y \, dx - 2x \, dy) &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \iint_R (-2 - 3) \, dx \, dy \\ &= \int_0^3 \int_0^4 (-5) \, dx \, dy = \int_0^3 (-20) \, dy = \boxed{-60}.\end{aligned}$$

9. Here $P(x, y) = xy^2$ and $Q(x, y) = x^2y$, so that

$$\oint_C (xy^2 \, dx + x^2y \, dy) = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \iint_R (2xy - 2xy) \, dx \, dy = \iint_R 0 \, dx \, dy = \boxed{0}.$$

10. Here $P(x, y) = y \sin(xy)$ and $Q(x, y) = x \sin(xy)$, so that

$$\begin{aligned}\oint_C (y \sin(xy) \, dx + x \sin(xy) \, dy) &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy \\ &= \iint_R ((\sin(xy) + xy \cos(xy)) - (\sin(xy) + xy \cos(xy))) \, dx \, dy = \iint_R 0 \, dx \, dy = \boxed{0}.\end{aligned}$$

11. Here $P(x, y) = -x^2y$ and $Q(x, y) = y^2x$, so that

$$\oint_C (-x^2y \, dx + y^2x \, dy) = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \iint_R (y^2 + x^2) \, dx \, dy.$$

Convert to polar coordinates; the integral becomes

$$\iint_R (y^2 + x^2) \, dx \, dy = \int_0^1 \int_0^{2\pi} r^2 \cdot r \, d\theta \, dr = 2\pi \int_0^1 r^3 \, dr = 2\pi \left[\frac{1}{4}r^4 \right]_0^1 = \boxed{\frac{\pi}{2}}.$$

12. Here $P(x, y) = y(x^2 + y^2) = x^2y + y^3$ and $Q(x, y) = -x(x^2 + y^2) = -x^3 - xy^2$, so that

$$\begin{aligned}\oint_C [y(x^2 + y^2) dx - x(x^2 + y^2) dy] &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \iint_R ((-3x^2 - y^2) - (x^2 + 3y^2)) dx dy = -4 \iint_R (x^2 + y^2) dx dy.\end{aligned}$$

Using the integral from Problem 11, we get

$$-4 \iint_R (x^2 + y^2) dx dy = -4 \cdot \frac{\pi}{2} = \boxed{-2\pi}.$$

13. Here $P(x, y) = x^2 - y^3$ and $Q(x, y) = x^2 + y^2$, so that

$$\begin{aligned}\oint_C [(x^2 - y^3) dx + (x^2 + y^2) dy] &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \iint_R (2x - (-3y^2)) dx dy = \iint_R (2x + 3y^2) dx dy.\end{aligned}$$

Convert to polar coordinates; then $x = r \cos \theta$, $y^2 = r^2 \sin^2 \theta$, and the integral becomes

$$\begin{aligned}\iint_R (2x + 3y^2) dx dy &= \int_0^1 \int_0^{2\pi} (2r \cos \theta + 3r^2 \sin^2 \theta) \cdot r d\theta dr \\ &= \int_0^1 \int_0^{2\pi} \left(2r^2 \cos \theta + \frac{3}{2}r^3 - \frac{3}{2}r^3 \cos(2\theta) \right) d\theta dr \\ &= \int_0^1 \left[2r^2 \sin \theta + \frac{3}{2}r^3 \theta - \frac{3}{4}r^3 \sin(2\theta) \right]_0^{2\pi} dr \\ &= \int_0^1 \frac{3}{2}r^3 \cdot 2\pi dr \\ &= \int_0^1 3\pi r^3 dr \\ &= \left[\frac{3\pi}{4} r^4 \right]_0^1 = \boxed{\frac{3\pi}{4}}.\end{aligned}$$

14. Here $P(x, y) = xy^3 + \sin x$ and $Q(x, y) = x^2y^2 + 4x$, so that

$$\oint_C [(xy^3 + \sin x) dx + (x^2y^2 + 4x) dy] = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R (2xy + 4 - 3xy^2) dx dy.$$

Convert to polar coordinates; then $x = r \cos \theta$, $y = r \sin \theta$, and the integral becomes

$$\begin{aligned}\iint_R (2xy + 4 - 3xy^2) dx dy &= \int_0^1 \int_0^{2\pi} (2(r \cos \theta)(r \sin \theta) + 4 - 3(r \cos \theta)(r \sin \theta)^2) r d\theta dr \\ &= \int_0^1 \int_0^{2\pi} (2r^3 \cos \theta \sin \theta + 4r - 3r^4 \cos \theta \sin^2 \theta) d\theta dr \\ &= \int_0^1 [r^3 \sin^2 \theta + 4r\theta - r^4 \sin^3 \theta]_0^{2\pi} dr \\ &= \int_0^1 8\pi r dr \\ &= [4\pi r^2]_0^1 = \boxed{4\pi}.\end{aligned}$$

15. With $P(x, y) = x^2 + y$ and $Q(x, y) = x - y^2$, we get

$$\oint_C [(x^2 + y) dx + (x - y^2) dy] = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R (1 - 1) dx dy = \boxed{0}.$$

16. The region is

Since R is both x -simple and y -simple, we can choose the order of integration; integrate first with respect to y . With $P(x, y) = 4x^2 - 8y^2$ and $Q(x, y) = y - 6xy$, we get

$$\begin{aligned} \oint_C [(4x^2 - 8y^2) dx + (y - 6xy) dy] &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \iint_R (-6y - (-16y)) dx dy \\ &= \int_0^1 \int_{x^2}^{\sqrt{x}} 10y dy dx \\ &= \int_0^1 [5y^2]_{x^2}^{\sqrt{x}} dx \\ &= \int_0^1 (5x - 5x^4) dx \\ &= \left[\frac{5}{2}x^2 - x^5 \right]_0^1 = \boxed{\frac{3}{2}}. \end{aligned}$$

17. Note that $x = y^2$ is the same as $y = \pm\sqrt{x}$, so the region bounded by $y = x^2$ and $x = y^2$ is the same as that bounded by $y = x^2$ and $y = \sqrt{x}$, which is shown in Problem 16. Since R is both x -simple and y -simple, we can choose the order of integration; integrate first with respect to y . With

$P(x, y) = x^2 - x^2y$ and $Q(x, y) = xy^2$, we get

$$\begin{aligned}
 \oint_C [(x^2 - x^2y) dx + xy^2 dy] &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\
 &= \iint_R (y^2 - (-x^2)) dx dy \\
 &= \int_0^1 \int_{x^2}^{\sqrt{x}} (x^2 + y^2) dy dx \\
 &= \int_0^1 \left[x^2y + \frac{1}{3}y^3 \right]_{x^2}^{\sqrt{x}} dx \\
 &= \int_0^1 \left(\left(x^{5/2} + \frac{1}{3}x^{3/2} \right) - \left(x^4 + \frac{1}{3}x^6 \right) \right) dx \\
 &= \int_0^1 \left(x^{5/2} + \frac{1}{3}x^{3/2} - x^4 - \frac{1}{3}x^6 \right) dx \\
 &= \left[\frac{2}{7}x^{7/2} + \frac{2}{15}x^{5/2} - \frac{1}{5}x^5 - \frac{1}{21}x^7 \right]_0^1 \\
 &= \boxed{\frac{6}{35}}.
 \end{aligned}$$

18. The region is

Since R is y -simple, we integrate first with respect to x . With $P(x, y) = x^2 - y^2$ and $Q(x, y) = xy$, we get

$$\begin{aligned}
 \oint_C [(x^2 - y^2) dx + xy dy] &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\
 &= \iint_R (y - (-2y)) dx dy \\
 &= \int_{-1}^1 \int_{y^2}^1 3y dx dy \\
 &= \int_{-1}^1 [3xy]_{y^2}^1 dy \\
 &= \int_{-1}^1 (3y - 3y^3) dy \\
 &= \left[\frac{3}{2}y^2 - \frac{3}{4}y^4 \right]_{-1}^1 = \boxed{0}.
 \end{aligned}$$

19. The region is

The curve is more easily described as a function of y , namely $x = y^2$, so regard this as a y -simple region (it is x -simple as well) and integrate first with respect to x . With $P(x, y) = \frac{1}{y}$ and $Q(x, y) = \frac{1}{x}$, we get

$$\begin{aligned}
 \oint_C \left[\frac{1}{y} dx + \frac{1}{x} dy \right] &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\
 &= \iint_R \left(-\frac{1}{x^2} + \frac{1}{y^2} \right) dx dy \\
 &= \int_1^3 \int_{y^2}^9 \left(-\frac{1}{x^2} + \frac{1}{y^2} \right) dx dy \\
 &= \int_1^3 \left[\frac{1}{x} + \frac{x}{y^2} \right]_{y^2}^9 dy \\
 &= \int_1^3 \left(\frac{1}{9} + \frac{9}{y^2} - \frac{1}{y^2} - \frac{y^2}{y^2} \right) dy \\
 &= \int_1^3 \left(\frac{8}{y^2} - \frac{8}{9} \right) dy \\
 &= \left[-\frac{8}{y} - \frac{8}{9}y \right]_1^3 \\
 &= -\frac{8}{3} - \frac{8}{3} + 8 + \frac{8}{9} = \boxed{\frac{32}{9}}.
 \end{aligned}$$

20. The region is

With $P(x, y) = x^2y$ and $Q(x, y) = -y^2x$, we get

$$\oint_C [x^2y dx - y^2x dy] = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R (-y^2 - x^2) dx dy.$$

Convert to polar coordinates, giving

$$\begin{aligned}
 \iint_R (-y^2 - x^2) \, dx \, dy &= \int_0^a \int_0^\pi (-r^2) \cdot r \, d\theta \, dr \\
 &= \int_0^a [-r^3 \theta]_0^\pi \, dr \\
 &= \pi \int_0^a (-r^3) \, dr \\
 &= \pi \left[-\frac{1}{4} r^4 \right]_0^a = \boxed{-\frac{\pi}{4} a^4}.
 \end{aligned}$$

21. Since the region is the interior of a circle of radius 2 centered at the origin, and $P(x, y) = \frac{y}{x^2+y^2}$ and $Q(x, y) = -\frac{x}{x^2+y^2}$ are not defined at the origin, Green's Theorem does not apply, so we must compute the line integral. Parametrize the circle by $x(t) = 2 \cos t$, $y(t) = 2 \sin t$ for $0 \leq t \leq 2\pi$. Then

$$\begin{aligned}
 \oint_C (P(x, y) \, dx + Q(x, y) \, dy) &= \int_0^{2\pi} \left(\frac{2 \sin t}{(2 \sin t)^2 + (2 \cos t)^2} \cdot (-2 \sin t) - \frac{2 \cos t}{(2 \sin t)^2 + (2 \cos t)^2} \cdot (2 \cos t) \right) dt \\
 &= \int_0^{2\pi} \left(-\frac{4 \sin^2 t + 4 \cos^2 t}{4 \sin^2 t + 4 \cos^2 t} \right) dt \\
 &= \int_0^{2\pi} (-1) \, dt = \boxed{-2\pi}.
 \end{aligned}$$

22. The curve is a circle of radius 1 centered at $(2, -3)$, so it does not contain the origin (which is at a distance of $\sqrt{2^2 + 3^2} = \sqrt{13} > 1$ from $(2, -3)$). Therefore $P(x, y)$, $Q(x, y)$, and their derivatives are continuous on the interior of the circle. Since

$$\begin{aligned}
 \frac{\partial Q(x, y)}{\partial x} &= \frac{\partial}{\partial x} \left(-\frac{x}{x^2 + y^2} \right) = \frac{x^2 - y^2}{(x^2 + y^2)^2} \\
 \frac{\partial P(x, y)}{\partial y} &= \frac{\partial}{\partial y} \left(\frac{y}{x^2 + y^2} \right) = \frac{x^2 - y^2}{(x^2 + y^2)^2},
 \end{aligned}$$

the vector field is conservative by the converse of the Conservative Vector Field Theorem. Since the curve C is closed, the line integral is $\boxed{\text{zero}}$.

23. Since the region is the interior of an ellipse centered at the origin, and $P(x, y) = \frac{y}{x^2+y^2}$ and $Q(x, y) = -\frac{x}{x^2+y^2}$ are not defined at the origin, Green's Theorem does not apply. However, P , Q , and their derivatives are continuous away from the origin, and this ellipse can be continuously deformed to the circle of radius 2 centered at the origin by intermediate curves that do not contain the origin; see the following figure:

So by the theorem preceding Example 4, if D is the circle $x^2 + y^2 = 4$, then

$$\oint_C \frac{y \, dx - x \, dy}{x^2 + y^2} = \oint_D \frac{y \, dx - x \, dy}{x^2 + y^2}.$$

By Problem 21, the latter integral is $\boxed{-2\pi}$.

24. Since the region is the interior of an ellipse centered at the origin, and $P(x, y) = \frac{y}{x^2 + y^2}$ and $Q(x, y) = -\frac{x}{x^2 + y^2}$ are not defined at the origin, Green's Theorem does not apply. However, P , Q , and their derivatives are continuous away from the origin, and this ellipse can be continuously deformed to the circle of radius 2 centered at the origin by intermediate curves that do not contain the origin; see the following figure:

So by the theorem preceding Example 4, if D is the circle $x^2 + y^2 = 4$, then

$$\oint_C \frac{y \, dx - x \, dy}{x^2 + y^2} = \oint_D \frac{y \, dx - x \, dy}{x^2 + y^2}.$$

By Problem 21, the latter integral is $\boxed{-2\pi}$.

25. The region is

Treat this as an x -simple region. Then by Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_{-1}^2 \int_{x^2}^{x+2} 2 \, dy \, dx \\
 &= \frac{1}{2} \int_{-1}^2 [2y]_{x^2}^{x+2} dx \\
 &= \frac{1}{2} \int_{-1}^2 (2x + 4 - 2x^2) \, dx \\
 &= \frac{1}{2} \left[x^2 + 4x - \frac{2}{3}x^3 \right]_{-1}^2 \\
 &= \frac{1}{2} \left(\left(4 + 8 - \frac{16}{3} \right) - \left(1 - 4 + \frac{2}{3} \right) \right) \\
 &= \boxed{\frac{9}{2}}.
 \end{aligned}$$

26. The region is

Treat this as an x -simple region. Then by Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_{-1}^1 \int_{x^2-1}^0 2 \, dy \, dx \\
 &= \frac{1}{2} \int_{-1}^1 [2y]_{x^2-1}^0 \, dx \\
 &= \frac{1}{2} \int_{-1}^1 (2 - 2x^2) \, dx \\
 &= \frac{1}{2} \left[2x - \frac{2}{3}x^3 \right]_{-1}^1 \\
 &= \boxed{\frac{4}{3}}.
 \end{aligned}$$

27. The region is

Treat this as an x -simple region. Then by Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_0^1 \int_{x^3}^{x^2} 2 \, dy \, dx \\
 &= \frac{1}{2} \int_0^1 [2y]_{x^3}^{x^2} \, dx \\
 &= \frac{1}{2} \int_0^1 (2x^2 - 2x^3) \, dx \\
 &= \frac{1}{2} \left[\frac{2}{3}x^3 - \frac{1}{2}x^4 \right]_0^1 \\
 &= \boxed{\frac{1}{12}}.
 \end{aligned}$$

28. The region is

Treat this as an x -simple region. Then by Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_0^4 \int_{x^2/4}^{2\sqrt{x}} 2 \, dy \, dx \\
 &= \frac{1}{2} \int_0^4 [2y]_{x^2/4}^{2\sqrt{x}} dx \\
 &= \frac{1}{2} \int_0^4 \left(4\sqrt{x} - \frac{x^2}{2} \right) dx \\
 &= \frac{1}{2} \left[\frac{8}{3} x^{3/2} - \frac{1}{6} x^3 \right]_0^4 \\
 &= \boxed{\frac{16}{3}}.
 \end{aligned}$$

29. The region is

Treat this as an x -simple region. Then by Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_2^5 \int_0^{1/\sqrt{x-1}} 2 \, dy \, dx \\
 &= \frac{1}{2} \int_2^5 [2y]_0^{1/\sqrt{x-1}} dx \\
 &= \frac{1}{2} \int_2^5 \frac{2}{\sqrt{x-1}} dx \\
 &= \frac{1}{2} \int_2^5 2(x-1)^{-1/2} dx \\
 &= \frac{1}{2} \left[4(x-1)^{1/2} \right]_2^5 \\
 &= \boxed{2}.
 \end{aligned}$$

30. The region is

Treat this as an x -simple region. Then by Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_0^1 \int_{x^{3/2}}^x 2 \, dy \, dx \\
 &= \frac{1}{2} \int_0^1 [2y]_{x^{3/2}}^x dx \\
 &= \frac{1}{2} \int_0^1 (2x - 2x^{3/2}) dx \\
 &= \frac{1}{2} \left[x^2 - \frac{4}{5} x^{5/2} \right]_0^1 \\
 &= \boxed{\frac{1}{10}}.
 \end{aligned}$$

31. The region is

Treat this as an x -simple region; then $xy = 2$ is the curve $y = \frac{2}{x}$. By Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_1^2 \int_{2/x}^{3-x} 2 \, dy \, dx \\
 &= \frac{1}{2} \int_1^2 [2y]_{2/x}^{3-x} dx \\
 &= \frac{1}{2} \int_1^2 \left(6 - 2x - \frac{4}{x} \right) dx \\
 &= \frac{1}{2} [6x - x^2 - 4 \ln x]_1^2 \\
 &= \frac{1}{2} ((12 - 4 - 4 \ln 2) - (6 - 1 - 4 \ln 1)) \\
 &= \boxed{\frac{3}{2} - 2 \ln 2}.
 \end{aligned}$$

32. The region is

To find the points of intersection of the two curves, solve each for y , giving $y = \frac{\sqrt{3}}{x}$ and $y = \sqrt{4-x^2}$; these are equal when $\frac{\sqrt{3}}{x} = \sqrt{4-x^2}$. Squaring gives $\frac{3}{x^2} = 4-x^2$, so that $x^4-4x^2+3 = (x^2-3)(x^2-1) = 0$. Since we are working in the first quadrant only, the points of intersection are at $x = 1$ and $x = \sqrt{3}$, which correspond to $y = \sqrt{3}$ and $y = 1$. So the intersection points are $(1, \sqrt{3})$ and $(\sqrt{3}, 1)$. By Green's Theorem for Area, the area of the region is

$$\begin{aligned}
 A &= \frac{1}{2} \oint_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \iint_R \left(\frac{\partial x}{\partial x} - \frac{\partial(-y)}{\partial y} \right) dy \, dx \\
 &= \frac{1}{2} \int_1^{\sqrt{3}} \int_{\sqrt{3}/x}^{\sqrt{4-x^2}} 2 \, dy \, dx \\
 &= \frac{1}{2} \int_1^{\sqrt{3}} [2y]_{\sqrt{3}/x}^{\sqrt{4-x^2}} dx \\
 &= \frac{1}{2} \int_1^{\sqrt{3}} \left(2\sqrt{4-x^2} - \frac{2\sqrt{3}}{x} \right) dx \\
 &= \int_1^{\sqrt{3}} \sqrt{4-x^2} \, dx - \int_1^{\sqrt{3}} \frac{\sqrt{3}}{x} \, dx.
 \end{aligned}$$

To integrate the first term, use the trigonometric substitution $x = 2 \sin \theta$; then $4 - x^2 = 4 - 4 \sin^2 \theta = \cos^2 \theta$; since we are working in the first quadrant, we can take $\sqrt{4-x^2} = \cos \theta$. Further, $dx = 2 \cos \theta \, d\theta$. Also, $x = 1$ corresponds to $\theta = \frac{\pi}{6}$ and $x = \sqrt{3}$ to $\theta = \frac{\pi}{3}$. So the integral becomes

$$\begin{aligned}
 A &= \int_1^{\sqrt{3}} \sqrt{4-x^2} \, dx - \int_1^{\sqrt{3}} \frac{\sqrt{3}}{x} \, dx \\
 &= \int_{\pi/6}^{\pi/3} 2 \cos \theta \cdot 2 \cos \theta \, d\theta - \int_1^{\sqrt{3}} \frac{\sqrt{3}}{x} \, dx \\
 &= \int_{\pi/6}^{\pi/3} 4 \cos^2 \theta \, d\theta - \left[\sqrt{3} \ln x \right]_1^{\sqrt{3}} \\
 &= \int_{\pi/6}^{\pi/3} 4 \left(\frac{1}{2} + \frac{1}{2} \cos(2\theta) \right) d\theta - \sqrt{3} \ln \sqrt{3} \\
 &= \int_{\pi/6}^{\pi/3} (2 + 2 \cos(2\theta)) \, d\theta - \frac{\sqrt{3}}{2} \ln 3 \\
 &= [2\theta + \sin(2\theta)]_{\pi/6}^{\pi/3} - \frac{\sqrt{3}}{2} \ln 3 \\
 &= \left(\frac{2\pi}{3} + \sin \frac{2\pi}{3} \right) - \left(\frac{\pi}{3} + \sin \frac{\pi}{3} \right) - \frac{\sqrt{3}}{2} \ln 3 \\
 &= \boxed{\frac{\pi}{3} - \frac{\sqrt{3}}{2} \ln 3}.
 \end{aligned}$$

Applications and Extensions

33. We are given a parametrization of the cycloid. In order to use Green's formula for the area, we want a parametrization of the boundary of that area under the cycloid; a plot of the cycloid is

While the area is given by a counterclockwise parametrization, the parametrization we are given for the curve is clockwise (left to right). So we will parametrize the line along the bottom clockwise as well, by

$$C_1 : x(t) = 2\pi(1 - t), \quad y(t) = 0, \quad 0 \leq t \leq 1,$$

and negate the sum of the two line integrals to get the area. Note that

$$C_1 : x'(t) = -2\pi, \quad y'(t) = 0, \quad C_2 : x'(t) = 2\pi - 2\pi \cos(2\pi t), \quad y'(t) = 2\pi \sin(2\pi t).$$

Then the area is

$$\begin{aligned} A &= -\frac{1}{2} \left(\int_{C_1} (-y \, dx + x \, dy) + \int_{C_2} (-y \, dx + x \, dy) \right) \\ &= -\frac{1}{2} \int_0^1 (-0 \cdot (-2\pi) - 2\pi(1 - t) \cdot 0) \, dt \\ &\quad - \frac{1}{2} \int_0^1 [-(1 - \cos(2\pi t)) \cdot (2\pi - 2\pi \cos(2\pi t)) + (2\pi t - \sin(2\pi t)) \cdot (2\pi \sin(2\pi t))] \, dt \\ &= -\frac{1}{2} \int_0^1 [-2\pi + 2\pi \cos(2\pi t) + 2\pi \cos(2\pi t) - 2\pi \cos^2(2\pi t) + 4\pi^2 t \sin(2\pi t) - 2\pi \sin^2(2\pi t)] \, dt \\ &= -\frac{1}{2} \int_0^1 [-2\pi + 4\pi \cos(2\pi t) + 4\pi^2 t \sin(2\pi t) - 2\pi] \, dt \\ &= \int_0^1 [2\pi - 2\pi \cos(2\pi t) - 2\pi^2 t \sin(2\pi t)] \, dt. \end{aligned}$$

Integrate $t \sin(2\pi t)$ using integration by parts with $u = t$ and $dv = \sin(2\pi t) \, dt$, so that $du = dt$ and $v = -\frac{1}{2\pi} \cos(2\pi t)$. Then

$$\begin{aligned} A &= \int_0^1 [2\pi - 2\pi \cos(2\pi t) - 2\pi^2 t \sin(2\pi t)] \, dt \\ &= [2\pi t - \sin(2\pi t)]_0^1 - 2\pi^2 \left[\left[-\frac{1}{2\pi} t \cos(2\pi t) \right]_0^1 + \frac{1}{2\pi} \int_0^1 \cos(2\pi t) \, dt \right] \\ &= 2\pi - 2\pi^2 \left[-\frac{1}{2\pi} + \frac{1}{2\pi} \left[\frac{1}{2\pi} \sin(2\pi t) \right]_0^1 \right] \\ &= 2\pi - \pi \left[-1 + \left[\frac{1}{2\pi} \sin(2\pi t) \right]_0^1 \right] \\ &= \boxed{3\pi}. \end{aligned}$$

34. A diagram of the hypocycloid is given in the text. Using the given parametrization for $0 \leq t \leq 2\pi$, we have

$$x'(t) = -3 \cos^2 t \sin t, \quad y'(t) = 3 \sin^2 t \cos t.$$

Then the area enclosed by the hypocycloid is

$$\begin{aligned}
 A &= \frac{1}{2} \int_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \int_0^{2\pi} (-\sin^3 t \cdot (-3 \cos^2 t \sin t) + \cos^3 t \cdot 3 \sin^2 t \cos t) \, dt \\
 &= \frac{3}{2} \int_0^{2\pi} (\sin^4 t \cos^2 t + \sin^2 t \cos^4 t) \, dt \\
 &= \frac{3}{2} \int_0^{2\pi} ((\sin^2 t + \cos^2 t) \sin^2 t \cos^2 t) \, dt \\
 &= \frac{3}{2} \int_0^{2\pi} \sin^2 t \cos^2 t \, dt \\
 &= \frac{3}{2} \int_0^{2\pi} \frac{1}{4} \sin^2(2t) \, dt \\
 &= \frac{3}{8} \int_0^{2\pi} \left(\frac{1}{2} - \frac{1}{2} \cos(4t) \right) \, dt \\
 &= \frac{3}{16} \int_0^{2\pi} (1 - \cos(4t)) \, dt \\
 &= \frac{3}{16} \left[t - \frac{1}{4} \sin(4t) \right]_0^{2\pi} \\
 &= \boxed{\frac{3}{8}\pi}.
 \end{aligned}$$

35. The loop of the Folium of Descartes is

With the given parametrization,

$$x'(t) = \frac{6(1 - 2t^3)}{(1 + t^3)^2}, \quad y'(t) = \frac{6(2t - t^4)}{(1 + t^3)^2}.$$

Note that $(x(t), y(t)) \rightarrow (0, 0)$ as $t \rightarrow \infty$, so the area is

$$\begin{aligned}
 A &= \frac{1}{2} \int_C (-y \, dx + x \, dy) \\
 &= \frac{1}{2} \int_0^\infty \left(-\frac{6t^2}{1+t^3} \cdot \frac{6(1-2t^3)}{(1+t^3)^2} + \frac{6t}{1+t^3} \cdot \frac{6(2t-t^4)}{(1+t^3)^2} \right) dt \\
 &= \frac{1}{2} \int_0^\infty \frac{-36t^2(1-2t^3) + 36t(2t-t^4)}{(1+t^3)^3} dt \\
 &= 36 \cdot \frac{1}{2} \int_0^\infty \frac{-t^2 + 2t^5 + 2t^2 - t^5}{(1+t^3)^3} dt \\
 &= 18 \int_0^\infty \frac{t^5 + t^2}{(1+t^3)^3} dt \\
 &= 18 \int_0^\infty \frac{t^2}{(1+t^3)^2} dt.
 \end{aligned}$$

Now make the substitution $u = 1 + t^3$, so that $du = 3t^2 \, dt$. $t = 0$ corresponds to $u = 1$, and the upper bound remains ∞ . Then we get

$$\begin{aligned}
 A &= 18 \int_0^\infty \frac{t^2}{(1+t^3)^2} dt \\
 &= 18 \cdot \frac{1}{3} \int_1^\infty u^{-2} du \\
 &= 6 \lim_{b \rightarrow \infty} \int_1^b u^{-2} du \\
 &= 6 \lim_{b \rightarrow \infty} [-u^{-1}]_1^b \\
 &= 6 \lim_{b \rightarrow \infty} \left(-\frac{1}{b} + 1 \right) \\
 &= \boxed{6}.
 \end{aligned}$$

36. The region is

Since this is a semicircle of radius 2, its area is $A = \frac{1}{2} \cdot \pi \cdot 2^2 = 2\pi$. We wish to compute

$$\bar{x} = \frac{1}{4\pi} \oint_C x^2 \, dy, \quad \bar{y} = -\frac{1}{4\pi} \oint_C y^2 \, dx.$$

For the first integral, using Green's Theorem with $P(x, y) = 0$ and $Q(x, y) = x^2$, we get

$$\bar{x} = \frac{1}{4\pi} \oint_C x^2 \, dy = \frac{1}{4\pi} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx \, dy = \frac{1}{4\pi} \iint_R 2x \, dx \, dy.$$

Convert to polar coordinates, giving

$$\bar{x} = \frac{1}{4\pi} \iint_R 2x \, dx \, dy = \frac{1}{4\pi} \int_0^2 \int_0^\pi 2r \cos \theta \cdot r \, d\theta \, dr = \frac{1}{4\pi} \int_0^2 [2r^2 \sin \theta]_0^\pi \, dr = 0.$$

(Note that this is what one would expect from symmetry.) For the second integral, again use Green's Theorem, now with $P(x, y) = y^2$ and $Q(x, y) = 0$, to get

$$\begin{aligned} \bar{y} &= -\frac{1}{4\pi} \oint_C y^2 \, dx = -\frac{1}{4\pi} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \, dx \, dy \\ &= -\frac{1}{4\pi} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \, dx \, dy \\ &= -\frac{1}{4\pi} \iint_R (-2y) \, dx \, dy \\ &= \frac{1}{4\pi} \int_{-2}^2 \int_0^{\sqrt{4-x^2}} 2y \, dy \, dx \\ &= \frac{1}{4\pi} \int_{-2}^2 [y^2]_0^{\sqrt{4-x^2}} \, dx \\ &= \frac{1}{4\pi} \int_{-2}^2 (4 - x^2) \, dx \\ &= \frac{1}{4\pi} \left[4x - \frac{x^3}{3} \right]_{-2}^2 = \frac{8}{3\pi}. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \boxed{\left(0, \frac{8}{3\pi} \right)}.$$

37. The region is

To compute its area, we integrate

$$A = \int_{-1}^1 (1 - x^2) \, dx = \left[x - \frac{x^3}{3} \right]_{-1}^1 = \frac{4}{3}.$$

Then $\frac{1}{2A} = \frac{3}{8}$, and we wish to compute

$$\bar{x} = \frac{3}{8} \oint_C x^2 \, dy, \quad \bar{y} = -\frac{3}{8} \oint_C y^2 \, dx.$$

For the first integral, using Green's Theorem with $P(x, y) = 0$ and $Q(x, y) = x^2$, we get

$$\begin{aligned}
 \bar{x} &= \frac{3}{8} \oint_C x^2 dy = \frac{3}{8} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\
 &= \frac{3}{8} \iint_R 2x dx dy \\
 &= \frac{3}{8} \int_{-1}^1 \int_{x^2}^1 2x dy dx \\
 &= \frac{3}{8} \int_{-1}^1 [2xy]_{x^2}^1 dx \\
 &= \frac{3}{8} \int_{-1}^1 (2x - 2x^3) dx \\
 &= \frac{3}{8} \left[x^2 - \frac{1}{2} x^4 \right]_{-1}^1 = 0.
 \end{aligned}$$

(Note that this is what one would expect from symmetry.) For the second integral, again use Green's Theorem, now with $P(x, y) = y^2$ and $Q(x, y) = 0$, to get

$$\begin{aligned}
 \bar{y} &= -\frac{3}{8} \oint_C y^2 dx = -\frac{3}{8} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\
 &= -\frac{3}{8} \iint_R (-2y) dx dy \\
 &= \frac{3}{8} \int_{-1}^1 \int_{x^2}^1 2y dy dx \\
 &= \frac{3}{8} \int_{-1}^1 [y^2]_{x^2}^1 dx \\
 &= \frac{3}{8} \int_{-1}^1 (1 - x^4) dx \\
 &= \frac{3}{8} \left[x - \frac{1}{5} x^5 \right]_{-1}^1 = \frac{3}{5}.
 \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \boxed{\left(0, \frac{3}{5} \right)}.$$

38. The region is

The figure is a triangle with base and height each equal to 1, so its area is $A = \frac{1}{2}$, so that $\frac{1}{2A} = 1$. Note that the region is defined by $0 \leq x \leq 1$ and $0 \leq y \leq 1 - x$. We wish to compute

$$\bar{x} = \oint_C x^2 dy, \quad \bar{y} = - \oint_C y^2 dx.$$

For the first integral, using Green's Theorem with $P(x, y) = 0$ and $Q(x, y) = x^2$, we get

$$\begin{aligned} \bar{x} &= \oint_C x^2 dy = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \iint_R 2x dx dy \\ &= \int_0^1 \int_0^{1-x} 2x dy dx \\ &= \int_0^1 [2xy]_0^{1-x} dx \\ &= \int_0^1 2x(1-x) dx \\ &= \int_0^1 (2x - 2x^2) dx \\ &= \left[x^2 - \frac{2}{3}x^3 \right]_0^1 = \frac{1}{3}. \end{aligned}$$

For the second integral, again use Green's Theorem, now with $P(x, y) = y^2$ and $Q(x, y) = 0$, to get

$$\begin{aligned} \bar{y} &= - \oint_C y^2 dx = - \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= - \iint_R (-2y) dx dy \\ &= \int_0^1 \int_0^{1-x} 2y dy dx \\ &= \int_0^1 [y^2]_0^{1-x} dx \\ &= \int_0^1 (1-x)^2 dx \\ &= \left[-\frac{1}{3}(1-x)^3 \right]_0^1 = \frac{1}{3}. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{1}{3}, \frac{1}{3} \right).$$

39. The region is

The figure is a trapezoid with bases 1 and 2 and height 1, so its area is $A = \frac{1}{2}(1+2) \cdot 1 = \frac{3}{2}$, and therefore $\frac{1}{2A} = \frac{1}{3}$. Note that the region is defined by $0 \leq x \leq 1$ and $0 \leq y \leq 1+x$. We wish to compute

$$\bar{x} = \frac{1}{2A} \oint_C x^2 dy, \quad \bar{y} = -\frac{1}{2A} \oint_C y^2 dx.$$

For the first integral, using Green's Theorem with $P(x, y) = 0$ and $Q(x, y) = x^2$, we get

$$\begin{aligned} \bar{x} &= \frac{1}{3} \oint_C x^2 dy = \frac{1}{3} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \frac{1}{3} \iint_R 2x dx dy \\ &= \frac{1}{3} \int_0^1 \int_0^{1+x} 2x dy dx \\ &= \frac{1}{3} \int_0^1 [2xy]_0^{1+x} dx \\ &= \frac{1}{3} \int_0^1 2x(1+x) dx \\ &= \frac{1}{3} \int_0^1 (2x + 2x^2) dx \\ &= \frac{1}{3} \left[x^2 + \frac{2}{3}x^3 \right]_0^1 = \frac{5}{9}. \end{aligned}$$

For the second integral, again use Green's Theorem, now with $P(x, y) = y^2$ and $Q(x, y) = 0$, to get

$$\begin{aligned} \bar{y} &= -\frac{1}{3} \oint_C y^2 dx = -\frac{1}{3} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= -\frac{1}{3} \iint_R (-2y) dx dy \\ &= \frac{1}{3} \int_0^1 \int_0^{1+x} 2y dy dx \\ &= \frac{1}{3} \int_0^1 [y^2]_0^{1+x} dx \\ &= \frac{1}{3} \int_0^1 (1+x)^2 dx \\ &= \frac{1}{3} \left[\frac{1}{3}(1+x)^3 \right]_0^1 = \frac{7}{9}. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{5}{9}, \frac{7}{9} \right).$$

40. A diagram of the hypocycloid is in the text. Using the given parametrization for $0 \leq t \leq \frac{\pi}{2}$, we have

$$x'(t) = -3a \cos^2 t \sin t, \quad y'(t) = 3a \sin^2 t \cos t.$$

Parametrize the boundary of the first-quadrant region in question as

$$C_1 : x(t) = at, \quad y(t) = 0, \quad 0 \leq t \leq 1 \quad x'(t) = a, \quad y'(t) = 0$$

$$C_2 : x(t) = a \cos^3 t, \quad y(t) = a \sin^3 t, \quad 0 \leq t \leq \frac{\pi}{2} \quad x'(t) = -3a \cos^2 t \sin t, \quad y'(t) = 3a \sin^2 t \cos t$$

$$C_3 : x(t) = 0, \quad y(t) = a(1-t), \quad 0 \leq t \leq 1 \quad x'(t) = 0, \quad y'(t) = -a.$$

Then the area enclosed by the hypocycloid in the first quadrant is

$$A = \frac{1}{2} \oint_C (-y dx + x dy) = \frac{1}{2} \int_{C_1} (-y dx + x dy) + \frac{1}{2} \int_{C_2} (-y dx + x dy) + \frac{1}{2} \int_{C_3} (-y dx + x dy).$$

The first and third integrals are each zero, since in the first integral $-y dx + x dy = -0 \cdot a + at \cdot 0 = 0$ and in the third, $-y dx + x dy = -a(1-t) \cdot 0 + 0 \cdot (-a) = 0$. So the area is determined by the second integral:

$$\begin{aligned} A &= \frac{1}{2} \int_{C_2} (-y dx + x dy) = \frac{1}{2} \int_0^{\pi/2} (-a \sin^3 t \cdot (-3a \cos^2 t \sin t) + a \cos^3 t \cdot 3a \sin^2 t \cos t) dt \\ &= \frac{3}{2} a^2 \int_0^{\pi/2} (\sin^4 t \cos^2 t + \sin^2 t \cos^4 t) dt \\ &= \frac{3}{2} a^2 \int_0^{\pi/2} ((\sin^2 t + \cos^2 t) \sin^2 t \cos^2 t) dt \\ &= \frac{3}{2} a^2 \int_0^{\pi/2} \sin^2 t \cos^2 t dt \\ &= \frac{3}{2} a^2 \int_0^{\pi/2} \frac{1}{4} \sin^2(2t) dt \\ &= \frac{3}{8} a^2 \int_0^{\pi/2} \left(\frac{1}{2} - \frac{1}{2} \cos(4t) \right) dt \\ &= \frac{3}{16} a^2 \int_0^{\pi/2} (1 - \cos(4t)) dt \\ &= \frac{3}{16} a^2 \left[t - \frac{1}{4} \sin(4t) \right]_0^{\pi/2} = \frac{3}{32} \pi a^2. \end{aligned}$$

Then $\frac{1}{2A} = \frac{16}{3\pi a^2}$. We wish to compute

$$\bar{x} = \frac{1}{2A} \oint_C x^2 dy, \quad \bar{y} = -\frac{1}{2A} \oint_C y^2 dx,$$

As before, C consists of C_1 , C_2 , and C_3 , and both integrals are zero along both C_1 and C_3 , since along C_1

$$x^2 dy = (at)^2 \cdot 0 = 0, \quad y^2 dx = 0^2 \cdot a = 0,$$

and along C_3

$$x^2 dy = 0^2 \cdot (-a), \quad y^2 dx = (a(1-t))^2 \cdot 0 = 0.$$

So the coordinates of the center of mass are determined by C_2 . For the first integral, we get

$$\begin{aligned} \bar{x} &= \frac{16}{3\pi a^2} \int_{C_2} x^2 dy = \frac{16}{3\pi a^2} \int_0^{\pi/2} (a \cos^3 t)^2 \cdot 3a \sin^2 t \cos t dt \\ &= \frac{16}{3\pi a^2} \cdot 3a^3 \int_0^{\pi/2} \sin^2 t \cos^7 t dt \\ &= \frac{16}{\pi} a \int_0^{\pi/2} \sin^2 t (1 - \sin^2 t)^3 \cos t dt \\ &= \frac{16}{\pi} a \int_0^{\pi/2} (\sin^2 t - 3\sin^4 t + 3\sin^6 t - \sin^8 t) \cos t dt \\ &= \frac{16}{\pi} a \left[\frac{1}{3} \sin^2 t - \frac{3}{5} \sin^5 t + \frac{3}{7} \sin^7 t - \frac{1}{9} \sin^9 t \right]_0^{\pi/2} \\ &= \frac{256a}{315\pi}. \end{aligned}$$

For the second integral, again use Green's Theorem, now with $P(x, y) = y^2$ and $Q(x, y) = 0$, to get

$$\begin{aligned}
 \bar{y} &= -\frac{16}{3\pi a^2} \int_{C_2} y^2 dx = -\frac{16}{3\pi a^2} \int_0^{\pi/2} (a \sin^3 t)^2 \cdot (-3a \cos^2 t \sin t) dt \\
 &= \frac{16}{3\pi a^2} \cdot 3a^3 \int_0^{\pi/2} \cos^2 t \sin^7 t dt \\
 &= \frac{16}{\pi} a \int_0^{\pi/2} \cos^2 t (1 - \cos^2 t)^3 \sin t dt \\
 &= \frac{16}{\pi} a \int_0^{\pi/2} (\cos^2 t - 3\cos^4 t + 3\cos^6 t - \cos^8 t) \sin t dt \\
 &= \frac{16}{\pi} a \left[-\frac{1}{3} \cos^3 t + \frac{3}{5} \cos^5 t - \frac{3}{7} \cos^7 t + \frac{1}{9} \cos^9 t \right]_0^{\pi/2} \\
 &= \frac{256a}{315\pi}.
 \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{256a}{315\pi}, \frac{256a}{315\pi} \right).$$

41. Since the two curves form a closed path C , both components of $\mathbf{F}$ as well as their derivatives are continuous everywhere, and

$$\frac{\partial Q}{\partial x} = 0 = \frac{\partial P}{\partial y},$$

Green's Theorem tells us that

$$\oint_C \mathbf{F} \cdot \mathbf{r} = \oint_C (P dx + Q dy) = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R 0 dx dy = \boxed{0}.$$

Therefore no work is done.

42. This path is a circle C of radius 3 centered at the origin. We have $P(x, y) = e^x + 2y$ and $Q(x, y) = e^y - x$, so the work done is

$$W = \oint_C P(x, y) dx + Q(x, y) dy = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R (-1 - 2) dx dy = -3 \iint_R 1 dx dy.$$

But this integral is -3 times the area of the circle, which is $\pi \cdot 3^2 = 9\pi$, so the work done is $\boxed{-27\pi}$.

43. The region is

We have

$$P(x, y) = \ln(1 + x^2) - x^2 \cos y, \quad Q(x, y) = \frac{x^3}{3} \cos y - e^{\cos y},$$

$$\frac{\partial P}{\partial y} = x^2 \sin y, \quad \frac{\partial Q}{\partial x} = x^2 \cos y.$$

Then by Green's Theorem,

$$\begin{aligned} \oint_C \left\{ [\ln(1 + x^2) - x^2 \cos y] dx + \left(\frac{x^3}{3} \cos y - e^{\cos y} \right) dy \right\} &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \iint_R x^2 (\cos y - \sin y) dx dy \\ &= \int_0^1 \int_0^{x^3} x^2 (\cos y - \sin y) dy dx \\ &= \int_0^1 [x^2 (\sin y + \cos y)]_0^{x^3} dx \\ &= \int_0^1 (x^2 \sin x^3 + x^2 \cos x^3 - x^2) dx \\ &= \left[-\frac{1}{3} \cos x^3 + \frac{1}{3} \sin x^3 - \frac{1}{3} x^3 \right]_0^1 \\ &= \boxed{\frac{1}{3} (\sin 1 - \cos 1)}. \end{aligned}$$

44. The region R is the area between circles centered at the origin of radii 1 and 3:

Let C_3 be the circle of radius 3, and R_3 be the region inside that circle; let C_1 be the circle of radius 1, and R_1 be the region inside that circle. Denote by C the properly oriented boundary of the region in question. We have $P(x, y) = y^3$ and $Q(x, y) = -x^3$, so that $\frac{\partial P}{\partial y} = 3y^2$ and $\frac{\partial Q}{\partial x} = -3x^2$. Then by Green's Theorem for Multiply Connected Regions

$$\begin{aligned} \oint_C [y^3 dx - x^3 dy] &= \oint_{C_3} [y^3 dx - x^3 dy] - \oint_{C_1} [y^3 dx - x^3 dy] \\ &= \iint_{R_3} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy - \iint_{R_1} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \iint_{R_3} (-3x^2 - 3y^2) dx dy - \iint_{R_1} (-3x^2 - 3y^2) dx dy \\ &= -3 \left(\iint_{R_3} (x^2 + y^2) dx dy - \iint_{R_1} (x^2 + y^2) dx dy \right). \end{aligned}$$

To compute these integrals, convert to polar coordinates:

$$\begin{aligned}
 & -3 \left(\iint_{R_3} (x^2 + y^2) \, dx \, dy - \iint_{R_1} (x^2 + y^2) \, dx \, dy \right) \\
 &= -3 \left(\int_0^3 \int_0^{2\pi} r^2 \cdot r \, d\theta \, dr - \int_0^1 \int_0^{2\pi} r^2 \cdot r \, d\theta \, dr \right) \\
 &= -3 \left(\int_0^3 [r^3 \theta]_0^{2\pi} \, dr - \int_0^1 [r^3 \theta]_0^{2\pi} \, dr \right) \\
 &= -6\pi \left(\int_0^3 r^3 \, dr - \int_0^1 r^3 \, dr \right) \\
 &= -6\pi \left(\left[\frac{1}{4} r^4 \right]_0^3 - \left[\frac{1}{4} r^4 \right]_0^1 \right) \\
 &= \boxed{-120\pi}.
 \end{aligned}$$

48. Answers will vary.

49. Since R is y -simple, suppose that the boundary of R consists of two smooth curves, $C_1 : x = h_1(y)$ and $C_2 : x = h_2(y)$, where $h_1(y) \leq h_2(y)$ for $c \leq y \leq d$. The situation is:

Then

$$\iint_R \frac{\partial Q}{\partial x} \, dx \, dy = \int_c^d \left[\int_{h_1(y)}^{h_2(y)} \frac{\partial Q}{\partial x} \, dx \right] dy = \int_c^d [Q(x, y)]_{h_1(y)}^{h_2(y)} \, dy = \int_c^d [Q(h_2(y), y) - Q(h_1(y), y)] \, dy.$$

Convert this to two separate integrals by reversing the integration bounds:

$$\int_c^d [Q(h_2(y), y) - Q(h_1(y), y)] \, dy = \int_c^d Q(h_2(y), y) \, dy + \int_d^c Q(h_1(y), y) \, dy.$$

By definition of the line integral, this is equal to

$$\int_{C_2} Q(x, y) \, dy + \int_{C_1} Q(x, y) \, dy = \oint_C Q(x, y) \, dy,$$

as desired.

50. Using Green's Theorem for Area, we know that

$$A = \frac{1}{2} \oint_C (-y \, dx + x \, dy).$$

Here $P(x, y) = -y$ and $Q(x, y) = x$, so applying Green's Theorem gives

$$A = \frac{1}{2} \oint_C (-y dx + x dy) = \frac{1}{2} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \frac{1}{2} \iint_R 2 dx dy = \iint_R 1 dx dy.$$

Similarly, we get

$$\begin{aligned} \oint_C x dy &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R (1 - 0) dx dy = \iint_R 1 dx dy \\ \oint_C (-y) dx &= \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \iint_R (0 - (-1)) dx dy = \iint_R 1 dx dy. \end{aligned}$$

So each of these integrals is equal to the area integral and we are done.

51. In order to apply Green's Theorem to convert the line integral to a double integral, P and Q must be continuous on the interior of the curve, and their first derivatives must be as well. Here,

$$P(x, y) = \frac{y}{(x^2 + y^2)^{3/2}} = y(x^2 + y^2)^{-3/2}, \quad Q(x, y) = -\frac{x}{(x^2 + y^2)^{3/2}} = -x(x^2 + y^2)^{-3/2},$$

so that P and Q are continuous everywhere except at the origin. Their derivatives are

$$\begin{aligned} \frac{\partial P}{\partial x} &= -\frac{3}{2}y(x^2 + y^2)^{-5/2} \cdot 2x = -3xy(x^2 + y^2)^{-5/2} \\ \frac{\partial P}{\partial y} &= (x^2 + y^2)^{-3/2} + y \cdot \left(-\frac{3}{2}(x^2 + y^2)^{-5/2} \cdot 2y \right) \\ &= (x^2 + y^2)^{-3/2} - 3y^2(x^2 + y^2)^{-5/2} \\ &= ((x^2 + y^2) - 3y^2)(x^2 + y^2)^{-5/2} = (x^2 - 2y^2)(x^2 + y^2)^{-5/2} \\ \frac{\partial Q}{\partial x} &= -(x^2 + y^2)^{-3/2} - x \cdot \left(-\frac{3}{2}(x^2 + y^2)^{-5/2} \cdot 2x \right) \\ &= -(x^2 + y^2)^{-3/2} + 3x^2(x^2 + y^2)^{-5/2} \\ &= (-(x^2 + y^2) + 3x^2)(x^2 + y^2)^{-5/2} = (2x^2 - y^2)(x^2 + y^2)^{-5/2} \\ \frac{\partial Q}{\partial y} &= -\left(-\frac{3}{2}x(x^2 + y^2)^{-5/2} \cdot 2y \right) = 3xy(x^2 + y^2)^{-5/2}. \end{aligned}$$

All of these are continuous everywhere except at the origin. Therefore Green's Theorem can be applied as long as neither the curve C nor its interior contains the origin.

Challenge Problems

52. Assume that the mass density of the lamina is 1 (otherwise, we would need to replace A by M , the mass, in the formula). With $P(x, y) = 0$ and $Q(x, y) = x^2$ we have, using Green's Theorem,

$$\frac{1}{2A} \oint_C x^2 dy = \frac{1}{2A} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \frac{1}{2A} \iint_R 2x dx dy = \frac{\iint_R x dx dy}{A}.$$

By the Mass of a Lamina Theorem in Section 14.4, this is the x -coordinate of the center of mass, $\bar{x}$. Next, with $P(x, y) = y^2$ and $Q(x, y) = 0$, we again have, using Green's Theorem,

$$-\frac{1}{2A} \oint_C y^2 dx = -\frac{1}{2A} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = -\frac{1}{2A} \iint_R (-2y) dx dy = \frac{\iint_R y dx dy}{A}.$$

Using the same theorem, we see that this is the y -coordinate of the center of mass, $\bar{y}$.

53. With $P(x, y) = -y^3$ and $Q(x, y) = x^3$, we have, using Green's Theorem,

$$\begin{aligned} \frac{1}{3} \oint_C (x^3 dy - y^3 dx) &= \frac{1}{3} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy \\ &= \frac{1}{3} \iint_R (3x^2 - (-3y^2)) dx dy \\ &= \iint_R (x^2 + y^2) dx dy. \end{aligned}$$

Using the formula for moments of inertia in Objective 2 of Section 4.4, we see that this is the moment of inertia I_O about the origin.

54. $\iint_R dx dy$ is the area of R . From Green's Formula for Area, we know that this integral is equal to

$$\iint_R dx dy = \frac{1}{2} \oint_C (x dy - y dx).$$

Now parametrize x and y as given in the exercise: $x = x(s, t)$ and $y = y(s, t)$. Then

$$dx = x_s ds + x_t dt, \quad dy = y_s ds + y_t dt,$$

so we get

$$\begin{aligned} \frac{1}{2} \oint_C (x dy - y dx) &= \frac{1}{2} \oint_{C'} (x(s, t) (y_s ds + y_t dt) - y(s, t) (x_s ds + x_t dt)) \\ &= \frac{1}{2} \oint_{C'} ((x(s, t)y_s - y(s, t)x_s) ds + (x(s, t)y_t - y(s, t)x_t) dt). \end{aligned} \quad (1)$$

Let

$$P(s, t) = x(s, t)y_s - y(s, t)x_s, \quad Q(s, t) = x(s, t)y_t - y(s, t)x_t.$$

Then

$$\begin{aligned} \frac{\partial P}{\partial t} &= x_t y_s + x(s, t)y_{st} - y_t x_s - y(s, t)x_{st} \\ \frac{\partial Q}{\partial s} &= x_s y_t + x(s, t)y_{ts} - y_s x_t - y(s, t)x_{ts}, \end{aligned}$$

so that (since the mixed partial derivatives are equal)

$$\frac{\partial Q}{\partial s} - \frac{\partial P}{\partial t} = x_s y_t - y_s x_t - x_t y_s + y_t x_s = 2(x_s y_t - x_t y_s).$$

Then applying Green's Theorem to (1), we get

$$\begin{aligned} \frac{1}{2} \oint_{C'} ((x(s, t)y_s - y(s, t)x_s) ds + (x(s, t)y_t - y(s, t)x_t) dt) &= \frac{1}{2} \iint_{R'} \left(\frac{\partial Q}{\partial s} - \frac{\partial P}{\partial t} \right) ds dt \\ &= \iint_{R'} (x_s y_t - x_t y_s) ds dt. \end{aligned}$$

Note that care should be taken that both regions are traversed in a counterclockwise direction.

55. By the Fundamental Theorem of Calculus, we have

$$\frac{\partial P}{\partial y} = \frac{\partial}{\partial y} \left(- \int \phi(x, y) dy \right) = -\phi(x, y), \quad \frac{\partial Q}{\partial x} = \frac{\partial}{\partial x} \left(\int \phi(x, y) dx \right) = \phi(x, y),$$

so that using Green's Theorem

$$\iint_R \phi(x, y) dx dy = \frac{1}{2} \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dx dy = \frac{1}{2} \oint_C (P dx + Q dy).$$

Now, using the Chain Rule,

$$dx = x_s ds + x_t dt, \quad dy = y_s ds + y_t dt,$$

so in the st -plane, the above integral is equal to

$$\frac{1}{2} \oint_{C'} (P(x_s ds + x_t dt) + Q(y_s ds + y_t dt)) = \frac{1}{2} \oint_{C'} ((Px_s + Qy_s) ds + (Px_t + Qy_t) dt).$$

Apply Green's Theorem again, in the st -plane, to get

$$\frac{1}{2} \iint_{R'} \left(\frac{\partial}{\partial s}(Px_t + Qy_t) - \frac{\partial}{\partial t}(Px_s + Qy_s) \right) ds dt. \quad (1)$$

Now expand each of these derivatives using the product rule together with the Chain Rule:

$$\begin{aligned} \frac{\partial}{\partial s}(Px_t + Qy_t) &= \frac{\partial P}{\partial s}x_t + Px_{ts} + \frac{\partial Q}{\partial s}y_t + Qy_{ts} \\ &= \left(\frac{\partial P}{\partial x}x_s + \frac{\partial P}{\partial y}y_s \right)x_t + Px_{ts} + \left(\frac{\partial Q}{\partial x}x_s + \frac{\partial Q}{\partial y}y_s \right)y_t + Qy_{ts} \\ &= \frac{\partial P}{\partial x}x_sx_t + \frac{\partial P}{\partial y}x_t y_s + Px_{ts} + \frac{\partial Q}{\partial x}x_s y_t + \frac{\partial Q}{\partial y}y_s y_t + Qy_{ts} \\ \frac{\partial}{\partial t}(Px_s + Qy_s) &= \frac{\partial P}{\partial t}x_s + Px_{st} + \frac{\partial Q}{\partial t}y_s + Qy_{st} \\ &= \left(\frac{\partial P}{\partial x}x_t + \frac{\partial P}{\partial y}y_t \right)x_s + Px_{st} + \left(\frac{\partial Q}{\partial x}x_t + \frac{\partial Q}{\partial y}y_t \right)y_s + Qy_{st} \\ &= \frac{\partial P}{\partial x}x_sx_t + \frac{\partial P}{\partial y}x_s y_t + Px_{st} + \frac{\partial Q}{\partial x}x_t y_s + \frac{\partial Q}{\partial y}y_s y_t + Qy_{st}. \end{aligned}$$

Subtract the second equation from the first. Note that mixed partials are equal, so we get

$$\begin{aligned} \frac{\partial}{\partial s}(Px_t + Qy_t) - \frac{\partial}{\partial t}(Px_s + Qy_s) &= \frac{\partial P}{\partial y}x_t y_s - \frac{\partial P}{\partial y}x_s y_t + \frac{\partial Q}{\partial x}x_s y_t - \frac{\partial Q}{\partial x}x_t y_s \\ &= \frac{\partial Q}{\partial x}(x_s y_t - x_t y_s) - \frac{\partial P}{\partial y}(x_s y_t - x_t y_s) \\ &= \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right)(x_s y_t - x_t y_s) \\ &= 2\phi(x(s, t), y(s, t))(x_s y_t - x_t y_s). \end{aligned}$$

Substitute into (1) to get

$$\begin{aligned} \frac{1}{2} \iint_{R'} \left(\frac{\partial}{\partial s}(Px_t + Qy_t) - \frac{\partial}{\partial t}(Px_s + Qy_s) \right) ds dt &= \frac{1}{2} \iint_{R'} 2\phi(x(s, t), y(s, t))(x_s y_t - x_t y_s) ds dt \\ &= \iint_{R'} \phi(x(s, t), y(s, t))(x_s y_t - x_t y_s) ds dt, \end{aligned}$$

as required.

15.6: Parametric Surfaces

Concepts and Vocabulary

1. (b), *tangent plane*, is correct. See the discussion following the definition of a smooth parametrization.
2. (c), *parametric surface*, is correct. See the definition at the start of the section.

3. (c), *sphere*, is correct. These are the parametric equations in spherical coordinates for a sphere of radius 5. See Example 4.
4. Since

$$\mathbf{r}(u, v) = (1 - u + 2v)\mathbf{i} + 4u\mathbf{j} + (2u + 3v - 7)\mathbf{k} = \langle 1, 0, -7 \rangle + \langle -1, 4, 2 \rangle u + \langle 2, 0, 3 \rangle v,$$

this is a plane through the point $(1, 0, -7)$ containing the two direction vectors $\langle -1, 4, 2 \rangle$ and $\langle 2, 0, 3 \rangle$.
 (a), *plane*, is correct.

Skill Building

5. (a) When $u = 0$, we get

$$\mathbf{r}(0, v) = (0 - 5v)\mathbf{i} + 2 \cdot 0\mathbf{j} + (-0 + v + 1)\mathbf{k} = \boxed{-5v\mathbf{i} + (v + 1)\mathbf{k}}.$$

This is a line through $(0, 0, 1)$ with direction vector $\langle -5, 0, 1 \rangle$. When $v = 0$, we get

$$\mathbf{r}(u, 0) = (u - 5 \cdot 0)\mathbf{i} + 2u\mathbf{j} + (-u + 0 + 1)\mathbf{k} = \boxed{u\mathbf{i} + 2u\mathbf{j} + (1 - u)\mathbf{k}}.$$

This is a line through $(0, 0, 1)$ with direction vector $\langle 1, 2, -1 \rangle$.

- (b) We start with the given system of equations:

$$\begin{aligned} x &= u - 5v \\ y &= 2u \\ z &= -u + v + 1. \end{aligned}$$

Add five times the third equation to the first to eliminate v , giving the system

$$\begin{aligned} x + 5z &= -4u + 5 \\ y &= 2u. \end{aligned}$$

Now add twice the second equation to the first, giving $\boxed{x + 2y + 5z = 5}$.

6. (a) When $u = 0$, we get

$$\mathbf{r}(0, v) = 0\mathbf{i} + v\mathbf{j} + (9 - 0^2 - v^2)\mathbf{k} = \boxed{v\mathbf{j} + (9 - v^2)\mathbf{k}}.$$

This is the parabola $z = 9 - y^2$ in the yz -plane. When $v = 0$, we get

$$\mathbf{r}(u, 0) = u\mathbf{i} + 0\mathbf{j} + (9 - u^2 - 0^2)\mathbf{k} = \boxed{u\mathbf{i} + (9 - u^2)\mathbf{k}}.$$

This is the parabola $z = 9 - x^2$ in the xz -plane.

- (b) We start with the given system of equations:

$$\begin{aligned} x &= u \\ y &= v \\ z &= 9 - u^2 - v^2. \end{aligned}$$

Square each of the first two equations and add them to the third, giving $z + x^2 + y^2 = 9$, or $\boxed{z = 9 - x^2 - y^2}$. This is a paraboloid.

7. (a) When $u = 0$, we get

$$\mathbf{r}(0, v) = 0 \cos v \mathbf{i} + 0 \sin v \mathbf{j} + 0 \mathbf{k} = \boxed{\mathbf{0}}.$$

This is a single point, the origin. When $v = 0$, we get

$$\mathbf{r}(u, 0) = u \cos 0 \mathbf{i} + u \sin 0 \mathbf{j} + u \mathbf{k} = \boxed{u \mathbf{i} + u \mathbf{k}}.$$

This is the line through the origin with direction vector $\langle 1, 0, 1 \rangle$.

- (b) We start with the given system of equations:

$$x = u \cos v$$

$$y = u \sin v$$

$$z = u.$$

Square all three equations and subtract the first two from the third, giving

$$z^2 - x^2 - y^2 = u^2 - u^2 \cos^2 v - u^2 \sin^2 v = u^2 - u^2 = 0.$$

This is the portion of the cone $\boxed{z^2 = x^2 + y^2}$ lying between the planes $z = 0$ and $z = 2$ (since $0 \leq u \leq 2$) and having positive y -coordinates (since $0 \leq v \leq \pi$).

8. (a) When $u = 0$, we get

$$\mathbf{r}(0, v) = \cos 0 \sin v \mathbf{i} + \sin 0 \sin v \mathbf{j} + \cos v \mathbf{k} = \boxed{\sin v \mathbf{i} + \cos v \mathbf{k}}.$$

When $v = 0$, we get

$$\mathbf{r}(u, 0) = \cos u \sin 0 \mathbf{i} + \sin u \sin 0 \mathbf{j} + \cos 0 \mathbf{k} = \boxed{\mathbf{k}}.$$

- (b) We start with the given system of equations:

$$x = \cos u \sin v$$

$$y = \sin u \sin v$$

$$z = \cos v.$$

Square all three equations and add them together, giving

$$x^2 + y^2 + z^2 = \cos^2 u \sin^2 v + \sin^2 u \sin^2 v + \cos^2 v = \sin^2 v + \cos^2 v = 1.$$

This is the hemisphere of radius 1 centered at the origin lying above the xy -plane (since $0 \leq v \leq \frac{\pi}{2}$), having equation $\boxed{x^2 + y^2 + z^2 = 1}$.

9. Let $x = u$ and $y = v$; then $z = 4 - u - 2v$. Since we want the portion in the first octant, we restrict $x = u \geq 0$ and $y = v \geq 0$. We also want $z \geq 0$, so that $4 - u - 2v \geq 0$ and therefore $0 \leq u \leq 4$ and $0 \leq v \leq 2 - \frac{1}{2}u$. So the parametrization is

$$\boxed{\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + (4 - u - 2v) \mathbf{k}, \quad 0 \leq u \leq 4, \quad 0 \leq v \leq 2 - \frac{1}{2}u.}$$

10. Let $x = u$ and $y = v$; then $z = e^{-u^2+v^2}$. Since we want the portion of this surface inside the cylinder $x^2 + y^2 = 4$, we want $x^2 + y^2 = u^2 + v^2 < 4$. So the parametrization is

$$\boxed{\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + e^{-u^2+v^2} \mathbf{k}, \quad u^2 + v^2 < 4.}$$

11. Let $x = u$ and $y = v$; then $z = \sin(u^2v)$. The curves $y = x + 2$ and $y = x^2$ are

Since we want the portion of this surface lying over the shaded region, we want $-1 \leq x \leq 2$, so that $-1 \leq u \leq 2$, and $u^2 \leq y = v \leq u + 2$. So the parametrization is

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + \sin(u^2v) \mathbf{k}, \quad -1 \leq u \leq 2, \quad u^2 \leq v \leq u + 2.$$

12. Let $x = u$ and $z = v$; then $y = 5 - e^{uv}$. Since we want the portion of this surface inside the cylinder $x^2 + z^2 = 1$, we want $0 \leq x^2 + z^2 = u^2 + v^2 < 1$. So the parametrization is

$$\mathbf{r}(u, v) = u \mathbf{i} + (5 - e^{uv}) \mathbf{j} + v \mathbf{k}, \quad u^2 + v^2 < 1.$$

13. (a) At $(7, 5, 4)$, the values of the parameters are determined by solving the equations

$$\begin{aligned} 3u + 2v &= 7 \\ 5u^3 &= 5 \\ v^2 &= 4. \end{aligned}$$

The second equation gives $u = 1$; substituting this into the first equation gives $v = 2$, which satisfies the third equation, so this point is indeed on the surface. Now,

$$\begin{aligned} \mathbf{r}_u &= \frac{\partial}{\partial u}(3u + 2v) \mathbf{i} + \frac{\partial}{\partial u}(5u^3) \mathbf{j} + \frac{\partial}{\partial u}(v^2) \mathbf{k} = 3 \mathbf{i} + 15u^2 \mathbf{j} \\ \mathbf{r}_v &= \frac{\partial}{\partial v}(3u + 2v) \mathbf{i} + \frac{\partial}{\partial v}(5u^3) \mathbf{j} + \frac{\partial}{\partial v}(v^2) \mathbf{k} = 2 \mathbf{i} + 2v \mathbf{k}. \end{aligned}$$

Then when $u = 1$ and $v = 2$ we have

$$\mathbf{r}_u(1, 2) = 3 \mathbf{i} + 15 \mathbf{j}, \quad \mathbf{r}_v(1, 2) = 2 \mathbf{i} + 4 \mathbf{k}.$$

Therefore a normal to the tangent plane at $(7, 5, 4)$ is given by

$$\langle 3, 15, 0 \rangle \times \langle 2, 0, 4 \rangle = \langle 60, -12, -30 \rangle,$$

so that the equation of the tangent plane is $60(x - 7) - 12(y - 5) - 30(z - 4) = 0$. Simplifying by dividing through by 6 and expanding the terms gives $10x - 2y - 5z = 40$.

- (b) The normal line to the tangent plane at the given point is the line whose direction vector is $\langle 60, -12, -30 \rangle$ through the point $(7, 5, 4)$. Divide the direction vector through by 6 to simplify, giving $\langle 10, -2, -5 \rangle$. A parametrization of the normal line is then

$$\mathbf{r}(t) = (7 + 10t) \mathbf{i} + (5 - 2t) \mathbf{j} + (4 - 5t) \mathbf{k}.$$

14. (a) At $(11, 1, -5)$, the values of the parameters are determined by solving the equations

$$\begin{aligned} 3u - v &= 11 \\ 2 - u - v &= 1 \\ 1 + 3v &= -5. \end{aligned}$$

The third equation gives $v = -2$; substituting that into the first equation gives $u = 3$. Those two values satisfy the remaining equation, so this point is indeed on the surface. Now,

$$\begin{aligned} \mathbf{r}_u &= \frac{\partial}{\partial u}(3u - v)\mathbf{i} + \frac{\partial}{\partial u}(2 - u - v)\mathbf{j} + \frac{\partial}{\partial u}(1 + 3v)\mathbf{k} = 3\mathbf{i} - \mathbf{j} \\ \mathbf{r}_v &= \frac{\partial}{\partial v}(3u - v)\mathbf{i} + \frac{\partial}{\partial v}(2 - u - v)\mathbf{j} + \frac{\partial}{\partial v}(1 + 3v)\mathbf{k} = -\mathbf{i} - \mathbf{j} + 3\mathbf{k}. \end{aligned}$$

Then when $u = 3$ and $v = -2$ we have

$$\mathbf{r}_u(3, -2) = 3\mathbf{i} - \mathbf{j}, \quad \mathbf{r}_v(3, -2) = -\mathbf{i} - \mathbf{j} + 3\mathbf{k}.$$

Therefore a normal to the tangent plane at $(11, 1, -5)$ is given by

$$\langle 3, -1, 0 \rangle \times \langle -1, -1, 3 \rangle = \langle -3, -9, -4 \rangle.$$

We can instead negate this vector, giving a normal of $\langle 3, 9, 4 \rangle$. Then the equation of the tangent plane is $3(x - 11) + 9(y - 1) + 4(z + 5) = 0$. Simplifying gives $\boxed{3x + 9y + 4z = 22}$. (Note that the given parametric surface is a plane, and that this equation is the equation of the plane in rectangular coordinates.)

- (b) The normal line to the tangent plane at the given point is the line with direction vector $\langle 3, 9, 4 \rangle$ through the point $(11, 1, -5)$; a parametrization of this line is

$$\boxed{\mathbf{r}(t) = (11 + 3t)\mathbf{i} + (1 + 9t)\mathbf{j} + (-5 + 4t)\mathbf{k}}.$$

15. (a) At $\left(5, \frac{5\sqrt{2}}{2}, \frac{5\sqrt{2}}{2}\right)$, the values of the parameters are determined by solving the equations

$$\begin{aligned} u &= 5 \\ u \cos v &= \frac{5\sqrt{2}}{2} \\ u \sin v &= \frac{5\sqrt{2}}{2}. \end{aligned}$$

The first equation gives $u = 5$; then the other two equations give $v = \frac{\pi}{4}$. Now,

$$\begin{aligned} \mathbf{r}_u &= \frac{\partial}{\partial u}(u)\mathbf{i} + \frac{\partial}{\partial u}(u \cos v)\mathbf{j} + \frac{\partial}{\partial u}(u \sin v)\mathbf{k} = \mathbf{i} + \cos v \mathbf{j} + \sin v \mathbf{k} \\ \mathbf{r}_v &= \frac{\partial}{\partial v}(u)\mathbf{i} + \frac{\partial}{\partial v}(u \cos v)\mathbf{j} + \frac{\partial}{\partial v}(u \sin v)\mathbf{k} = -u \sin v \mathbf{j} + u \cos v \mathbf{k}. \end{aligned}$$

Then when $u = 5$ and $v = \frac{\pi}{4}$ we have

$$\mathbf{r}_u\left(5, \frac{\pi}{4}\right) = \mathbf{i} + \frac{\sqrt{2}}{2}\mathbf{j} + \frac{\sqrt{2}}{2}\mathbf{k}, \quad \mathbf{r}_v\left(5, \frac{\pi}{4}\right) = -\frac{5\sqrt{2}}{2}\mathbf{j} + \frac{5\sqrt{2}}{2}\mathbf{k}$$

Therefore a normal to the tangent plane at $\left(5, \frac{5\sqrt{2}}{2}, \frac{5\sqrt{2}}{2}\right)$ is given by

$$\left\langle 1, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle \times \left\langle 0, -\frac{5\sqrt{2}}{2}, \frac{5\sqrt{2}}{2} \right\rangle = \left\langle 5, -\frac{5\sqrt{2}}{2}, -\frac{5\sqrt{2}}{2} \right\rangle.$$

Therefore the equation of the tangent plane is

$$5(x-5) - \frac{5\sqrt{2}}{2} \left(y - \frac{5\sqrt{2}}{2} \right) - \frac{5\sqrt{2}}{2} \left(z - \frac{5\sqrt{2}}{2} \right) = 0, \text{ or}$$

$$5x - \frac{5\sqrt{2}}{2}y - \frac{5\sqrt{2}}{2}z = 25 - \frac{25}{2} - \frac{25}{2} = 0.$$

Multiply through by 2 to clear fractions and divide through by $5\sqrt{2}$ to simplify, giving

$$\boxed{\sqrt{2}x - y - z = 0}.$$

- (b) We determine a normal vector to the tangent plane at the given point from the equation above; it is $\langle \sqrt{2}, -1, -1 \rangle$. The line with this direction vector through the point $\left(5, \frac{5\sqrt{2}}{2}, \frac{5\sqrt{2}}{2} \right)$ may be parametrized as

$$\boxed{\mathbf{r}(t) = (5 + \sqrt{2}t)\mathbf{i} + \left(\frac{5\sqrt{2}}{2} - t \right)\mathbf{j} + \left(\frac{5\sqrt{2}}{2} - t \right)\mathbf{k}}.$$

16. (a) At $\left(1, 0, \frac{\sqrt{3}}{2} \right)$, the values of the parameters are determined by solving the equations

$$\begin{aligned} 3 \cos u \sin v + 1 &= 1 \\ 2 \sin u \sin v - 1 &= 0 \\ \cos v &= \frac{\sqrt{3}}{2}. \end{aligned}$$

From $2 \sin u \sin v = 1$, we conclude that $\sin v \neq 0$. The first equation simplifies to $3 \cos u \sin v = 0$, so that since $\sin v \neq 0$, we must have $\cos u = 0$, so that $\sin u = \pm 1$. If $\sin u = 1$, then from the second equation $\sin v = \frac{1}{2}$; together with $\cos v = \frac{\sqrt{3}}{2}$ we get $v = \frac{\pi}{6}$ and $u = \frac{\pi}{2}$. If $\sin u = -1$, then the second equation gives $\sin v = -\frac{1}{2}$, so that $v = -\frac{\pi}{6}$ and $u = -\frac{\pi}{2}$. So the point actually has two possible values for u and v in the range $-\pi \leq u, v \leq \pi$; we use the first one, so that $u = \frac{\pi}{2}$ and $v = \frac{\pi}{6}$. Now,

$$\begin{aligned} \mathbf{r}_u &= \frac{\partial}{\partial u}(3 \cos u \sin v + 1)\mathbf{i} + \frac{\partial}{\partial u}(2 \sin u \sin v - 1)\mathbf{j} + \frac{\partial}{\partial u}(\cos v)\mathbf{k} = -3 \sin u \sin v \mathbf{i} + 2 \cos u \sin v \mathbf{j} \\ \mathbf{r}_v &= \frac{\partial}{\partial v}(3 \cos u \sin v + 1)\mathbf{i} + \frac{\partial}{\partial v}(2 \sin u \sin v - 1)\mathbf{j} + \frac{\partial}{\partial v}(\cos v)\mathbf{k} \\ &= 3 \cos u \cos v \mathbf{i} + 2 \sin u \cos v \mathbf{j} - \sin v \mathbf{k}. \end{aligned}$$

Then when $u = \frac{\pi}{2}$ and $v = \frac{\pi}{6}$ we have

$$\mathbf{r}_u \left(\frac{\pi}{2}, \frac{\pi}{6} \right) = -\frac{3}{2} \mathbf{i} \quad \mathbf{r}_v \left(\frac{\pi}{2}, \frac{\pi}{6} \right) = \sqrt{3} \mathbf{j} - \frac{1}{2} \mathbf{k}.$$

Therefore a normal to the tangent plane at $\left(1, 0, \frac{\sqrt{3}}{2} \right)$ is given by

$$\left\langle -\frac{3}{2}, 0, 0 \right\rangle \times \left\langle 0, \sqrt{3}, -\frac{1}{2} \right\rangle = \left\langle 0, -\frac{3}{4}, -\frac{3\sqrt{3}}{2} \right\rangle,$$

and so the equation of the tangent plane is

$$\begin{aligned} -\frac{3}{4}(y-0) - \frac{3\sqrt{3}}{2} \left(z - \frac{\sqrt{3}}{2} \right) &= 0, \text{ or} \\ 3y + 6\sqrt{3}z &= 9. \end{aligned}$$

Divide through by 3 to simplify, giving

$$\boxed{y + 2\sqrt{3}z = 3}.$$

- (b) The normal line to the tangent plane at the given point is the line whose direction vector is $\left\langle 0, -\frac{3}{4}, -\frac{3\sqrt{3}}{2} \right\rangle$ through the point $\left(1, 0, \frac{\sqrt{3}}{2}\right)$; a parametrization of this line is

$$\boxed{\mathbf{r}(t) = \mathbf{i} - \frac{3}{4}t\mathbf{j} + \left(\frac{\sqrt{3}}{2} - \frac{3\sqrt{3}}{2}t\right)\mathbf{k}}.$$

17. Start by finding the partial derivatives of $\mathbf{r}$:

$$\mathbf{r}_u(u, v) = \cos v \mathbf{i} + 3u^2 \mathbf{j} + \sin v \mathbf{k}$$

$$\mathbf{r}_v(u, v) = -u \sin v \mathbf{i} + u \cos v \mathbf{k}.$$

Then

$$\begin{aligned} \mathbf{r}_u \times \mathbf{r}_v &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos v & 3u^2 & \sin v \\ -u \sin v & 0 & u \cos v \end{vmatrix} \\ &= 3u^3 \cos v \mathbf{i} - (u \cos^2 v + u \sin^2 v) \mathbf{j} + 3u^3 \sin v \mathbf{k} \\ &= 3u^3 \cos v \mathbf{i} - u \mathbf{j} + 3u^3 \sin v \mathbf{k}. \end{aligned}$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{(3u^3 \cos v)^2 + u^2 + (3u^3 \sin v)^2} = \sqrt{9u^6 + u^2} = u\sqrt{9u^4 + 1}.$$

Then the surface area is

$$\int_0^1 \int_{-\pi}^{\pi} u\sqrt{9u^4 + 1} dv du = \int_0^1 \left[uv\sqrt{9u^4 + 1} \right]_{-\pi}^{\pi} du = 2\pi \int_0^1 u\sqrt{9u^4 + 1} du.$$

Now make the substitution $t = 3u^2$, so that $dt = 6u du$, or $du = \frac{1}{6u} dt = \frac{\sqrt{3}}{6\sqrt{t}} dt$. Then $u = 0$ corresponds to $t = 0$ and $u = 1$ to $t = 3$, and we get

$$2\pi \int_0^1 u\sqrt{9u^4 + 1} du = 2\pi \int_0^3 \frac{\sqrt{t}}{\sqrt{3}} \cdot \sqrt{t^2 + 1} \cdot \frac{\sqrt{3}}{6\sqrt{t}} dt = \frac{\pi}{3} \int_0^3 \sqrt{t^2 + 1} dt.$$

From Formula 49 in the tables in the Endnotes, this integral is

$$\begin{aligned} \frac{\pi}{3} \left[\frac{t}{2} \sqrt{t^2 + 1} + \frac{1}{2} \ln |t + \sqrt{t^2 + 1}| \right]_0^3 &= \frac{\pi}{3} \left(\frac{3}{2} \sqrt{10} + \frac{1}{2} \ln(3 + \sqrt{10}) \right) \\ &= \boxed{\pi \left(\frac{\sqrt{10}}{2} + \frac{1}{6} \ln(3 + \sqrt{10}) \right)}. \end{aligned}$$

18. Start by finding the partial derivatives of $\mathbf{r}$:

$$\mathbf{r}_u(u, v) = 6u \mathbf{i} + 2u \mathbf{j} - 2u \mathbf{k}$$

$$\mathbf{r}_v(u, v) = \mathbf{i} + \mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 6u & 2u & -2u \\ 1 & 0 & 1 \end{vmatrix} = 2u \mathbf{i} - 8u \mathbf{j} - 2u \mathbf{k}.$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{4u^2 + 64u^2 + 4u^2} = u\sqrt{72} = 6u\sqrt{2}.$$

Then the surface area is

$$\int_0^2 \int_{-1}^1 6u\sqrt{2} \, du \, dv = 6\sqrt{2} \int_0^2 [uv]_{-1}^1 \, du = 6\sqrt{2} \int_0^2 2u \, du = 6\sqrt{2} [u^2]_0^2 = \boxed{24\sqrt{2}}.$$

19. Solve the equation of the plane for z , giving $z = -\frac{1}{2}x + \frac{1}{4}y + \frac{3}{4}$. Parametrize the plane by

$$x = u, \quad y = v, \quad z = -\frac{1}{2}u + \frac{1}{4}v + \frac{3}{4},$$

so that $\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + (-\frac{1}{2}u + \frac{1}{4}v + \frac{3}{4})\mathbf{k}$. The bounds on u and v are given by the fact that $(x-2)^2 + y^2$ must lie inside the given cylinder, so we get $(u-2)^2 + v^2 \leq 4$. Let $0 \leq u \leq 4$; then $-\sqrt{4-(u-2)^2} \leq v \leq \sqrt{4-(u-2)^2}$. Next find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= \mathbf{i} - \frac{1}{2}\mathbf{k} \\ \mathbf{r}_v(u, v) &= \mathbf{j} + \frac{1}{4}\mathbf{k}.\end{aligned}$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -\frac{1}{2} \\ 0 & 1 & \frac{1}{4} \end{vmatrix} = \frac{1}{2}\mathbf{i} - \frac{1}{4}\mathbf{j} + \mathbf{k}.$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\left(\frac{1}{2}\right)^2 + \left(\frac{1}{4}\right)^2 + 1} = \frac{\sqrt{21}}{4}.$$

Then the surface area is

$$\begin{aligned}\int_0^4 \int_{-\sqrt{4-(u-2)^2}}^{\sqrt{4-(u-2)^2}} \frac{\sqrt{21}}{4} \, dv \, du &= \frac{\sqrt{21}}{4} \int_0^4 [v]_{-\sqrt{4-(u-2)^2}}^{\sqrt{4-(u-2)^2}} \, du \\ &= \frac{\sqrt{21}}{2} \int_0^4 \sqrt{4-(u-2)^2} \, du \\ &= \frac{\sqrt{21}}{2} \int_0^4 \sqrt{4u-u^2} \, du.\end{aligned}$$

By Formula 71 in the tables in the Endnotes, this is

$$\frac{\sqrt{21}}{2} \left[\frac{u-2}{2} \sqrt{4u-u^2} + 2 \cos^{-1} \left(\frac{2-x}{2} \right) \right]_0^4 = \frac{\sqrt{21}}{2} \cdot (2\pi) = \boxed{\pi\sqrt{21}}.$$

20. The paraboloid is

The paraboloid intersects $z = 0$ (the xy -plane) when $0 = 4 - x^2 - y^2$, so along the circle $x^2 + y^2 = 4$. Parametrize the paraboloid by

$$x = u, \quad y = v, \quad z = 4 - u^2 - v^2,$$

so that $\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + (4 - u^2 - v^2)\mathbf{k}$. The bounds on u and v are given by the fact that $x^2 + y^2$ must lie inside the circle of intersection, so we get $u^2 + v^2 \leq 4$. Let $-2 \leq u \leq 2$; then $-\sqrt{4 - u^2} \leq v \leq \sqrt{4 - u^2}$. Next find the partial derivatives of $\mathbf{r}$:

$$\mathbf{r}_u(u, v) = \mathbf{i} - 2u\mathbf{k}$$

$$\mathbf{r}_v(u, v) = \mathbf{j} - 2v\mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -2u \\ 0 & 1 & -2v \end{vmatrix} = 2u\mathbf{i} + 2v\mathbf{j} + \mathbf{k}.$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{4u^2 + 4v^2 + 1} = \sqrt{4(u^2 + v^2) + 1}$$

Then the surface area is

$$\iint_R \sqrt{4(u^2 + v^2) + 1} \, dA,$$

where R is a circle of radius 2 centered at the origin. Convert to polar coordinates, giving

$$\iint_R \sqrt{4(u^2 + v^2) + 1} \, dA = \int_0^2 \int_0^{2\pi} \sqrt{4r^2 + 1} \cdot r \, d\theta \, dr = 2\pi \int_0^2 r \sqrt{4r^2 + 1} \, dr.$$

Now make the substitution $t = 4r^2 + 1$, so that $dt = 8r \, dr$; then $r = 0$ corresponds to $t = 1$ and $r = 2$ to $t = 17$, and we get

$$2\pi \int_0^2 r \sqrt{4r^2 + 1} \, dr = \frac{\pi}{4} \int_1^{17} \sqrt{t} \, dt = \frac{\pi}{4} \left[\frac{2}{3} t^{3/2} \right]_1^{17} = \boxed{\frac{\pi}{6} (17\sqrt{17} - 1)}.$$

21. The given sphere intersects the plane $z = 2$ then $x^2 + y^2 + 4 = 16$, so when $x^2 + y^2 = 12$. Parametrize the sphere by

$$x = u, \quad y = v, \quad z = \sqrt{16 - u^2 - v^2},$$

so that $\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + \sqrt{16 - u^2 - v^2}\mathbf{k}$. The bounds on u and v are given by the fact that $x^2 + y^2$ must lie inside the circle of intersection, so we get $u^2 + v^2 \leq 12$. Let $-\sqrt{12} \leq u \leq \sqrt{12}$; then $-\sqrt{12 - u^2} \leq v \leq \sqrt{12 - u^2}$. Next find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= \mathbf{i} - \frac{u}{\sqrt{16 - u^2 - v^2}}\mathbf{k} \\ \mathbf{r}_v(u, v) &= \mathbf{j} - \frac{v}{\sqrt{16 - u^2 - v^2}}\mathbf{k}.\end{aligned}$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -\frac{u}{\sqrt{16 - u^2 - v^2}} \\ 0 & 1 & -\frac{v}{\sqrt{16 - u^2 - v^2}} \end{vmatrix} = \frac{u}{\sqrt{16 - u^2 - v^2}}\mathbf{i} + \frac{v}{\sqrt{16 - u^2 - v^2}}\mathbf{j} + \mathbf{k}.$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\left(\frac{u}{\sqrt{16 - u^2 - v^2}}\right)^2 + \left(\frac{v}{\sqrt{16 - u^2 - v^2}}\right)^2 + 1} = \sqrt{\frac{16}{16 - u^2 - v^2}} = \frac{4}{\sqrt{16 - u^2 - v^2}}.$$

Then the surface area is

$$\iint_R \frac{4}{\sqrt{16 - u^2 - v^2}} dA,$$

where R is a circle of radius $\sqrt{12}$ centered at the origin. Convert to polar coordinates, giving

$$\iint_R \frac{4}{\sqrt{16 - u^2 - v^2}} dA = \int_0^{\sqrt{12}} \int_0^{2\pi} \frac{4r}{\sqrt{16 - r^2}} d\theta dr = 2\pi \int_0^{\sqrt{12}} \frac{4r}{\sqrt{16 - r^2}} dr.$$

Now make the substitution $t = 16 - r^2$, so that $dt = -2r dr$; then $r = 0$ corresponds to $t = 16$ and $r = \sqrt{12}$ to $t = 4$, and we get

$$2\pi \int_0^{\sqrt{12}} \frac{4r}{\sqrt{16 - r^2}} dr = -4\pi \int_{16}^4 \frac{1}{\sqrt{t}} dt = -4\pi \left[2t^{1/2} \right]_{16}^4 = \boxed{16\pi}.$$

22. The cone is

The cone intersects $z = 3$ when $3 = 3\sqrt{x^2 + y^2}$, so when $x^2 + y^2 = 1$, and intersects $z = 6$ when $6 = 3\sqrt{x^2 + y^2}$, so when $x^2 + y^2 = 4$. Parametrize the cone by

$$x = u, \quad y = v, \quad z = 3\sqrt{u^2 + v^2},$$

so that $\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + 3\sqrt{u^2 + v^2}\mathbf{k}$. The bounds on u and v are given by the fact that $x^2 + y^2$ must lie between the two circles of intersection, so we get $1 \leq u^2 + v^2 \leq 4$. Next find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= \mathbf{i} + \frac{3u}{\sqrt{u^2 + v^2}}\mathbf{k} \\ \mathbf{r}_v(u, v) &= \mathbf{j} + \frac{3v}{\sqrt{u^2 + v^2}}\mathbf{k}.\end{aligned}$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & \frac{3u}{\sqrt{u^2 + v^2}} \\ 0 & 1 & \frac{3v}{\sqrt{u^2 + v^2}} \end{vmatrix} = -\frac{3u}{\sqrt{u^2 + v^2}}\mathbf{i} - \frac{3v}{\sqrt{u^2 + v^2}}\mathbf{j} + \mathbf{k}.$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\left(\frac{3u}{\sqrt{u^2 + v^2}}\right)^2 + \left(\frac{3v}{\sqrt{u^2 + v^2}}\right)^2 + 1} = \sqrt{10}.$$

Then the surface area is

$$\iint_R \sqrt{10} dA,$$

where R is the area between the circle of radius 1 centered at the origin and the circle of radius 2 centered at the origin. Convert to polar coordinates, giving

$$\iint_R \sqrt{10} dA = \int_1^2 \int_0^{2\pi} \sqrt{10} \cdot r d\theta dr = 2\pi\sqrt{10} \int_1^2 r dr = 2\pi\sqrt{10} \left[\frac{1}{2}r^2\right]_1^2 = \boxed{3\pi\sqrt{10}}.$$

23. This surface extends from $u = 0$ to $u = 4$, so from $z = 0$ to $z = -4$. The coordinate curve for $u = a$ is parametrized as $a \cos v \mathbf{i} + a \sin v \mathbf{j} - a \mathbf{k}$, so each cross-section parallel to the xy -plane is a circle. This fits surfaces **(D)** and **(E)**. The rectangular equation for this curve is determined by eliminating u and v from the equations $x = u \cos v$, $y = u \sin v$, $z = -u$. Squaring the first two equations gives $x^2 + y^2 = u^2$, so the rectangular equation is $z = -\sqrt{x^2 + y^2}$. This is a downward pointing cone, so **(E)** is correct.
24. Since the x -coordinate is parametrized by u^3 , it extends from $x = 0$ to $x = 64$. At $u = a$, the coordinate curve is parametrized as $a^3 \mathbf{i} + a \sin v \mathbf{j} + a \cos v \mathbf{k}$, which is a circle of radius a , so each cross-section parallel to the yz -plane is a circle. This fits surface **(C)**.
25. This surface extends from $u = z = 0$ to $u = z = 4$. The coordinate curve for $u = a$ is parametrized as $a \cos v \mathbf{i} + a \sin v \mathbf{j} + a \mathbf{k}$, so each cross-section parallel to the xy -plane is a circle. This fits surface **(B)**.
26. For each coordinate $x = u$, $0 \leq u \leq 4$, the coordinate curve is a circle of radius 2, since the y and z -coordinates are $(4 \sin v, 4 \cos v)$. So this surface is a cylinder, which is **(A)**.
27. Find the rectangular equation for this surface by eliminating u and v . Square $x = u \cos v$ and $y = u \sin v$ to get $x^2 + y^2 = u^2$; then

$$z = -u^3 = -(x^2 + y^2)^{3/2}.$$

This matches only surface **(D)**.

28. The coordinate curve at any value of u is given by $\mathbf{r}(u, v)$; since the y -coordinate is the cube of the x -coordinate, the curve has equation $y = x^3$ at $z = u$. This matches **(F)**.

Applications and Extensions

29. Using cylindrical coordinates, the cylinder $x^2 + y^2 = 16$ is parametrized as $r = \sqrt{x^2 + y^2} = 4$ and $0 \leq \theta \leq 2\pi$; the restriction that we have $0 \leq z \leq 3$ provides the third constraint. So the parametrization is

$$x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + z \mathbf{k} = \boxed{4 \cos \theta \mathbf{i} + 4 \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq 3}.$$

30. Using spherical coordinates, the sphere is parametrized as

$$\mathbf{r}(\theta, \phi) = 5 \cos \theta \sin \phi \mathbf{i} + 5 \sin \theta \sin \phi \mathbf{j} + 5 \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

See Example 4.

31. The two surfaces are

- (a) Using rectangular coordinates, since the surface lies above a disk in the xy -plane of radius 1 centered at $(1,0)$, we let $x = u$ for $0 \leq u \leq 2$ and $y = v$ for $-\sqrt{1-u^2} \leq v \leq \sqrt{1-u^2}$. These are a parametrization of the disk. Then the surface lying above that circle is given by $z = 9 - x^2 - y^2 = 9 - u^2 - v^2$. Therefore a parametrization of this portion of the paraboloid is

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + (9 - u^2 - v^2) \mathbf{k}, \quad 0 \leq u \leq 2, \quad -\sqrt{1-u^2} \leq v \leq \sqrt{1-u^2}.$$

- (b) The disk above which the surface lies is

The point shown, which is on a line at an angle of θ with the x -axis from the center, has coordinates $(\cos \theta, \sin \theta)$ with respect to the center, so its coordinates in the xy -plane are $(1 + \cos \theta, \sin \theta)$. The line from $(1, 0)$ to this point is the line $(1, 0) + r(\cos \theta, \sin \theta) = (1 + r \cos \theta, r \sin \theta)$ for $0 \leq r \leq 1$. As θ ranges from 0 to 2π , these lines sweep out the entire disk. If $x = 1 + r \cos \theta$ and $y = r \sin \theta$, then $z = 9 - x^2 - y^2 = 8 - r^2 - 2r \cos \theta$, so we can parametrize the surface as

$$\mathbf{r}(r, \theta) = (1 + r \cos \theta) \mathbf{i} + r \sin \theta \mathbf{j} + (8 - r^2 - 2r \cos \theta) \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

32. Converting the given equation to spherical coordinates gives $r^2 = 3r + r \cos \phi$, or $r(r - (3 + \cos \phi)) = 0$. Therefore $r = 3 + \cos \phi$. Then use the spherical coordinate transformations

$$x = r \cos \theta \sin \phi, \quad y = r \sin \theta \sin \phi, \quad z = r \cos \phi, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi$$

and substitute $3 + \cos \phi$ for r to get

$$\mathbf{r}(\theta, \phi) = (3 + \cos \phi) \cos \theta \sin \phi \mathbf{i} + (3 + \cos \phi) \sin \theta \sin \phi \mathbf{j} + (3 + \cos \phi) \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

33. (a) Considering only first octant points, we want $0 \leq x = u \leq 2$ and $0 \leq y = v \leq \sqrt{4 - x^2}$; then $z = \sqrt{4 - x^2 - y^2} = \sqrt{4 - u^2 - v^2}$. So the parametrization is

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + \sqrt{4 - u^2 - v^2} \mathbf{k}, \quad 0 \leq u \leq 2, \quad 0 \leq v \leq \sqrt{4 - u^2}.$$

- (b) Using cylindrical coordinates, the surface lies over the quarter-circle of radius 2 in the first quadrant, which is parametrized by $x = r \cos \theta$, $y = r \sin \theta$, $0 \leq r \leq 2$, $0 \leq \theta \leq \frac{\pi}{2}$; then $z = \sqrt{4 - x^2 - y^2} = \sqrt{4 - r^2}$. So the parametrization is

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + \sqrt{4 - r^2} \mathbf{k}, \quad 0 \leq r \leq 2, \quad 0 \leq \theta \leq \frac{\pi}{2}.$$

- (c) The full sphere is parametrized using spherical coordinates by

$$\mathbf{r}(\theta, \phi) = 2 \cos \theta \sin \phi \mathbf{i} + 2 \sin \theta \sin \phi \mathbf{j} + 2 \cos \phi, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

Referring to the definition of spherical coordinates, we see that the first octant corresponds to $0 \leq \theta \leq \frac{\pi}{2}$ and $0 \leq \phi \leq \frac{\pi}{2}$, so the desired parametrization is

$$\mathbf{r}(\theta, \phi) = 2 \cos \theta \sin \phi \mathbf{i} + 2 \sin \theta \sin \phi \mathbf{j} + 2 \cos \phi, \quad 0 \leq \theta \leq \frac{\pi}{2}, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

34. The surface is

- (a) Since z is a free variable, let $z = v$. Let $x = u$; then $y = \sqrt{3}u$; since $x \geq 0$ and $y \geq 0$ we want $u \geq 0$, but v is unrestricted. So the parametrization is

$$\mathbf{r}(u, v) = u\mathbf{i} + \sqrt{3}u\mathbf{j} + v\mathbf{k}, \quad u \geq 0.$$

- (b) Using cylindrical coordinates, z is again unrestricted, so let $z = v$. Since $\frac{y}{x} = \tan \theta = \frac{1}{\sqrt{3}}$, we have $\theta = \frac{\pi}{6}$. Finally, r is unrestricted since the graph is unbounded with increasing r . Therefore the desired parametrization is

$$\mathbf{r}(r, z) = r \cos \frac{\pi}{6} \mathbf{i} + r \sin \frac{\pi}{6} \mathbf{j} + z \mathbf{k} = \frac{\sqrt{3}}{2}r \mathbf{i} + \frac{1}{2}r \mathbf{j} + z \mathbf{k}.$$

- (c) As in the cylindrical case, $\frac{y}{x} = \tan \theta = \frac{1}{\sqrt{3}}$, so that $\theta = \frac{\pi}{6}$. Since z is unrestricted, we take $0 \leq \phi \leq \pi$. Finally, r is unrestricted since the graph is unbounded with increasing r . Therefore the desired parametrization is

$$\mathbf{r}(r, \phi) = r \cos \frac{\pi}{6} \sin \phi \mathbf{i} + r \sin \frac{\pi}{6} \sin \phi \mathbf{j} + r \cos \phi \mathbf{k} = \frac{\sqrt{3}}{2}r \sin \phi \mathbf{i} + \frac{1}{2}r \sin \phi \mathbf{j} + r \cos \phi \mathbf{k}.$$

35. (a) The values of u and v that give the point $\left(\frac{3\sqrt{2}}{2}, \frac{3\sqrt{2}}{2}, 1\right)$ are found by solving the three equations

$$\begin{aligned} \cos u(3 + \cos v) &= \frac{3\sqrt{2}}{2} \\ \sin u(3 + \cos v) &= \frac{3\sqrt{2}}{2} \\ \sin v &= 1. \end{aligned}$$

So $v = \frac{\pi}{2}$, and then $\cos v = 0$, so the first two equations become $3 \cos u = \frac{3\sqrt{2}}{2}$ and $3 \sin u = \frac{3\sqrt{2}}{2}$, so that $u = \frac{\pi}{4}$. Next, find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned} \mathbf{r}_u(u, v) &= -\sin u(3 + \cos v)\mathbf{i} + \cos u(3 + \cos v)\mathbf{j} \\ \mathbf{r}_v(u, v) &= -\cos u \sin v \mathbf{i} - \sin u \sin v \mathbf{j} + \cos v \mathbf{k}. \end{aligned}$$

When $u = \frac{\pi}{4}$ and $v = \frac{\pi}{2}$, these are

$$\begin{aligned}\mathbf{r}_u\left(\frac{\pi}{4}, \frac{\pi}{2}\right) &= -\sin\frac{\pi}{4}\left(3 + \cos\frac{\pi}{2}\right)\mathbf{i} + \cos\frac{\pi}{4}\left(3 + \cos\frac{\pi}{2}\right)\mathbf{j} = -\frac{3\sqrt{2}}{2}\mathbf{i} + \frac{3\sqrt{2}}{2}\mathbf{j} \\ \mathbf{r}_v\left(\frac{\pi}{4}, \frac{\pi}{2}\right) &= -\cos\frac{\pi}{4}\sin\frac{\pi}{2}\mathbf{i} - \sin\frac{\pi}{4}\sin\frac{\pi}{2}\mathbf{j} + \cos\frac{\pi}{2}\mathbf{k} = -\frac{\sqrt{2}}{2}\mathbf{i} - \frac{\sqrt{2}}{2}\mathbf{j}.\end{aligned}$$

Therefore a normal vector to the surface at the given point is

$$\left\langle -\frac{3\sqrt{2}}{2}, \frac{3\sqrt{2}}{2}, 0 \right\rangle \times \left\langle -\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, 0 \right\rangle = \langle 0, 0, 3 \rangle.$$

So the equation of the tangent plane at $\left(\frac{3\sqrt{2}}{2}, \frac{3\sqrt{2}}{2}, 1\right)$ is $3(z - 1) = 0$, or $\boxed{z = 1}$.

(b) The normal line has direction vector $\langle 0, 0, 3 \rangle$, so it has the parametrization

$$\boxed{\mathbf{r}(t) = \frac{3\sqrt{2}}{2}\mathbf{i} + \frac{3\sqrt{2}}{2}\mathbf{j} + (1 + 3t)\mathbf{k}.$$

36. Start by finding the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= -\sin u(2 + \cos v)\mathbf{i} + \cos u(2 + \cos v)\mathbf{j} \\ \mathbf{r}_v(u, v) &= -\cos u \sin v \mathbf{i} - \sin u \sin v \mathbf{j} + \cos v \mathbf{k}.\end{aligned}$$

Then

$$\begin{aligned}\mathbf{r}_u \times \mathbf{r}_v &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin u(2 + \cos v) & \cos u(2 + \cos v) & 0 \\ -\cos u \sin v & -\sin u \sin v & \cos v \end{vmatrix} \\ &= \cos u \cos v(2 + \cos v)\mathbf{i} + \sin u \cos v(2 + \cos v)\mathbf{j} + \sin v(2 + \cos v)\mathbf{k}.\end{aligned}$$

Next,

$$\begin{aligned}\|\mathbf{r}_u \times \mathbf{r}_v\| &= \sqrt{\cos^2 u \cos^2 v(2 + \cos v)^2 + \sin^2 u \cos^2 v(2 + \cos v)^2 + \sin^2 v(2 + \cos v)^2} \\ &= (2 + \cos v)\sqrt{(\cos^2 u + \sin^2 u) \cos^2 v + \sin^2 v} = 2 + \cos v.\end{aligned}$$

Then the surface area is

$$\int_0^{2\pi} \int_0^{2\pi} (2 + \cos v) dv du = \int_0^{2\pi} [2v + \sin v]_0^{2\pi} du = \int_0^{2\pi} 4\pi du = \boxed{8\pi^2}.$$

37. Start by finding the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= \cos(2v)\mathbf{i} + \sin(2v)\mathbf{j} \\ \mathbf{r}_v(u, v) &= -2u \sin(2v)\mathbf{i} + 2u \cos(2v)\mathbf{j} + \mathbf{k}.\end{aligned}$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos(2v) & \sin(2v) & 0 \\ -2u \sin(2v) & 2u \cos(2v) & 1 \end{vmatrix} = \sin(2v)\mathbf{i} - \cos(2v)\mathbf{j} + 2u\mathbf{k}.$$

Next,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\sin^2(2v) + \cos^2(2v) + 4u^2} = \sqrt{4u^2 + 1}.$$

Then the surface area is

$$\int_0^1 \int_0^{2\pi} \sqrt{4u^2 + 1} \, dv \, du = 2\pi \int_0^1 \sqrt{4u^2 + 1} \, du = 4\pi \int_0^1 \sqrt{u^2 + \frac{1}{4}} \, du.$$

Evaluate this integral using Formula 49 in the tables in the Endnotes, giving

$$\begin{aligned} 4\pi \int_0^1 \sqrt{u^2 + \frac{1}{4}} \, du &= 4\pi \left[\frac{u}{2} \sqrt{u^2 + \frac{1}{4}} + \frac{1}{8} \ln \left(u + \sqrt{u^2 + \frac{1}{4}} \right) \right]_0^1 \\ &= 4\pi \left(\frac{1}{2} \sqrt{\frac{5}{4}} + \frac{1}{8} \ln \left(1 + \sqrt{\frac{5}{4}} \right) - 0 - \frac{1}{8} \ln \left(0 + \sqrt{\frac{1}{4}} \right) \right) \\ &= 4\pi \left(\frac{\sqrt{5}}{4} + \frac{1}{8} \ln \left(1 + \frac{\sqrt{5}}{2} \right) - \frac{1}{8} \ln \frac{1}{2} \right) \\ &= \pi\sqrt{5} + \frac{\pi}{2} \ln \left(\frac{2 + \sqrt{5}}{2} \cdot 2 \right) = \boxed{\pi\sqrt{5} + \frac{\pi}{2} \ln(2 + \sqrt{5})}. \end{aligned}$$

38. Start by finding the partial derivatives of $\mathbf{r}$:

$$\begin{aligned} \mathbf{r}_u(u, v) &= \left(-2 \sin u - \frac{1}{2}v \sin \frac{u}{2} \right) \mathbf{i} + \left(2 \cos u - \frac{1}{2}v \sin \frac{u}{2} \right) \mathbf{j} - \frac{1}{2}v \cos \frac{u}{2} \mathbf{k} \\ \mathbf{r}_v(u, v) &= \cos \frac{u}{2} \mathbf{i} + \cos \frac{u}{2} \mathbf{j} - \sin \frac{u}{2} \mathbf{k}. \end{aligned}$$

Then (using a CAS to simplify)

$$\begin{aligned} \mathbf{r}_u \times \mathbf{r}_v &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 \sin u - \frac{1}{2}v \sin \frac{u}{2} & 2 \cos u - \frac{1}{2}v \sin \frac{u}{2} & -\frac{1}{2}v \cos \frac{u}{2} \\ \cos \frac{u}{2} & \cos \frac{u}{2} & -\sin \frac{u}{2} \end{vmatrix} \\ &= \left(\frac{v}{2} + \sin \frac{u}{2} - \sin \frac{3u}{2} \right) \mathbf{i} + \left(-\frac{v}{2} - \cos \frac{u}{2} + \cos \frac{3u}{2} \right) \mathbf{j} + \left(-2 \cos \frac{u}{2} (\cos u + \sin u) \right) \mathbf{k}. \end{aligned}$$

Next, again using technology,

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = 4 + \frac{v^2}{2} + v \cos \frac{u}{2} - v \cos \frac{3u}{2} + v \sin \frac{u}{2} + \sin u - v \sin \frac{3u}{2} + 2 \sin(2u) + \sin(3u).$$

Then the surface area is (using technology)

$$\int_0^{2\pi} \int_{-0.5}^{0.5} \|\mathbf{r}_u \times \mathbf{r}_v\| \, dv \, du \approx 12.236.$$

39. (a) Let $y' = \frac{y}{3}$ and $z' = \frac{z}{2}$; then the equation of the ellipsoid becomes

$$x^2 + (y')^2 + (z')^2 = 1.$$

This is a unit sphere in (x, y', z') coordinates. Using the standard parametrization for spherical coordinates, we have

$$x = \cos \theta \sin \phi, \quad y' = \sin \theta \sin \phi, \quad z' = \cos \phi, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

Now convert back to the original coordinate system by substituting $\frac{y}{3}$ for y' and multiplying that equation through by 3, and substituting $\frac{z}{2}$ for z' and multiplying that equation through by 2. This gives the parametrization

$$\mathbf{r}(\theta, \phi) = \boxed{\cos \theta \sin \phi \mathbf{i} + 3 \sin \theta \sin \phi \mathbf{j} + 2 \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi}.$$

(b) The ellipsoid is

(c) Differentiating the parametrization from part (a) gives

$$\begin{aligned}\mathbf{r}_\theta(\theta, \phi) &= -\sin \theta \sin \phi \mathbf{i} + 3 \cos \theta \sin \phi \mathbf{j} \\ \mathbf{r}_\phi(\theta, \phi) &= \cos \theta \cos \phi \mathbf{i} + 3 \sin \theta \cos \phi \mathbf{j} - 2 \sin \phi \mathbf{k},\end{aligned}$$

so that

$$\begin{aligned}\mathbf{r}_\theta \times \mathbf{r}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta \sin \phi & 3 \cos \theta \sin \phi & 0 \\ \cos \theta \cos \phi & 3 \sin \theta \cos \phi & -2 \sin \phi \end{vmatrix} \\ &= -6 \cos \theta \sin^2 \phi \mathbf{i} - 2 \sin \theta \sin^2 \phi \mathbf{j} - 3 \sin \phi \cos \phi \mathbf{k}.\end{aligned}$$

It follows that

$$\|\mathbf{r}_\theta \times \mathbf{r}_\phi\| = \sqrt{36 \cos^2 \theta \sin^4 \phi + 4 \sin^2 \theta \sin^4 \phi + 9 \sin^2 \phi \cos^2 \phi},$$

so that the surface area is

$$S = \int_0^{2\pi} \int_0^\pi \sqrt{36 \cos^2 \theta \sin^4 \phi + 4 \sin^2 \theta \sin^4 \phi + 9 \sin^2 \phi \cos^2 \phi} d\phi d\theta.$$

40. (a) The helicoid is

(b) A parametrization is given in the problem statement for part (a); that is the one we shall use. We have

$$\mathbf{r}(u, v) = u \cos(2v)\mathbf{i} + u \sin(2v)\mathbf{j} + v \mathbf{k}, \quad 0 \leq u \leq 3, \quad 0 \leq v \leq 2\pi.$$

(c) Find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= \cos(2v)\mathbf{i} + \sin(2v)\mathbf{j} \\ \mathbf{r}_v(u, v) &= -2u \sin(2v)\mathbf{i} + 2u \cos(2v)\mathbf{j} + \mathbf{k}.\end{aligned}$$

When $u = \frac{1}{3}$ and $v = \pi$, these are

$$\begin{aligned}\mathbf{r}_u\left(\frac{1}{3}, \pi\right) &= \cos(2\pi)\mathbf{i} + \sin(2\pi)\mathbf{j} = \mathbf{i} \\ \mathbf{r}_v\left(\frac{1}{3}, \pi\right) &= -\frac{2}{3}\sin(2\pi)\mathbf{i} + \frac{2}{3}\cos(2\pi)\mathbf{j} + \mathbf{k} = \frac{2}{3}\mathbf{j} + \mathbf{k}.\end{aligned}$$

Therefore a normal vector to the surface at the given point is

$$\langle 1, 0, 0 \rangle \times \left\langle 0, \frac{2}{3}, 1 \right\rangle = \left\langle 0, -1, \frac{2}{3} \right\rangle.$$

When $(u, v) = (\frac{1}{3}, \pi)$, the corresponding point on the helicoid is

$$\left(\frac{1}{3}\cos(2\pi), \frac{1}{3}\sin(2\pi), \pi\right) = \left(\frac{1}{3}, 0, \pi\right).$$

The equation of the tangent plane at that point is

$$0\left(x - \frac{1}{3}\right) - 1(y - 0) + \frac{2}{3}(z - \pi) = 0, \text{ or } -y + \frac{2}{3}z = \frac{2}{3}\pi, \text{ or } 3y - 2z = -2\pi.$$

(d) The normal line has direction vector $\langle 0, -1, \frac{2}{3} \rangle$ and passes through $(\frac{1}{3}, 0, \pi)$, so its parametric equations are

$$\boxed{\frac{1}{3}\mathbf{i} - t\mathbf{j} + \left(\pi + \frac{2}{3}t\right)\mathbf{k}}.$$

41. (a) Dini's surface is

(b) With the given parametrization, we have

$$\mathbf{r}(u, v) = 6 \cos u \sin v \mathbf{i} + 6 \sin u \sin v \mathbf{j} + \left(6 \left[\cos v + \ln \left(\tan \frac{v}{2} \right) \right] + u \right) \mathbf{k}.$$

Find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned} \mathbf{r}_u(u, v) &= -6 \sin u \sin v \mathbf{i} + 6 \cos u \sin v \mathbf{j} + \mathbf{k} \\ \mathbf{r}_v(u, v) &= 6 \cos u \cos v \mathbf{i} + 6 \sin u \cos v \mathbf{j} + 6 \left(-\sin v + \frac{1}{2} \frac{\sec^2 \frac{v}{2}}{\tan \frac{v}{2}} \right) \mathbf{k} \\ &= 6 \cos u \cos v \mathbf{i} + 6 \sin u \cos v \mathbf{j} + 6 \left(-\sin v + \frac{1}{2} \csc \frac{v}{2} \sec \frac{v}{2} \right) \mathbf{k} \\ &= 6 \cos u \cos v \mathbf{i} + 6 \sin u \cos v \mathbf{j} + 6 \left(-\sin v + \frac{1}{2 \sin \frac{v}{2} \cos \frac{v}{2}} \right) \mathbf{k} \\ &= 6 \cos u \cos v \mathbf{i} + 6 \sin u \cos v \mathbf{j} + 6 \left(-\sin v + \frac{1}{\sin v} \right) \mathbf{k} \\ &= 6 \cos u \cos v \mathbf{i} + 6 \sin u \cos v \mathbf{j} + 6(-\sin v + \csc v) \mathbf{k}. \end{aligned}$$

When $u = \frac{\pi}{3}$ and $v = \frac{\pi}{4}$, these are

$$\begin{aligned} \mathbf{r}_u \left(\frac{\pi}{3}, \frac{\pi}{4} \right) &= -6 \sin \frac{\pi}{3} \sin \frac{\pi}{4} \mathbf{i} + 6 \cos \frac{\pi}{3} \sin \frac{\pi}{4} \mathbf{j} + \mathbf{k} \\ &= -\frac{3\sqrt{6}}{2} \mathbf{i} + \frac{3\sqrt{2}}{2} \mathbf{j} + \mathbf{k} \\ \mathbf{r}_v \left(\frac{\pi}{3}, \frac{\pi}{4} \right) &= 6 \cos \frac{\pi}{3} \cos \frac{\pi}{4} \mathbf{i} + 6 \sin \frac{\pi}{3} \cos \frac{\pi}{4} \mathbf{j} + 6 \left(-\sin \frac{\pi}{4} + \csc \frac{\pi}{4} \right) \mathbf{k} \\ &= \frac{3\sqrt{2}}{2} \mathbf{i} + \frac{3\sqrt{6}}{2} \mathbf{j} + 6 \left(-\frac{\sqrt{2}}{2} + \sqrt{2} \right) \mathbf{k} \\ &= \frac{3\sqrt{2}}{2} \mathbf{i} + \frac{3\sqrt{6}}{2} \mathbf{j} + 3\sqrt{2} \mathbf{k}. \end{aligned}$$

Therefore a normal vector to the surface at the given point is

$$\left\langle -\frac{3\sqrt{6}}{2}, \frac{3\sqrt{2}}{2}, 1 \right\rangle \times \left\langle \frac{3\sqrt{2}}{2}, \frac{3\sqrt{6}}{2}, 3\sqrt{2} \right\rangle = \left\langle 9 - \frac{3\sqrt{6}}{2}, 9\sqrt{3} + \frac{3\sqrt{2}}{2}, -18 \right\rangle.$$

When $(u, v) = \left(\frac{\pi}{3}, \frac{\pi}{4} \right)$, the corresponding point on the helicoid is

$$\begin{aligned} &\left(6 \cos \frac{\pi}{3} \sin \frac{\pi}{4}, 6 \sin \frac{\pi}{3} \sin \frac{\pi}{4}, 6 \left[\cos \frac{\pi}{4} + \ln \left(\tan \frac{\pi}{8} \right) \right] + \frac{\pi}{3} \right) \\ &= \left(\frac{3\sqrt{2}}{2}, \frac{3\sqrt{6}}{2}, \frac{\pi}{3} + 6 \left[\frac{\sqrt{2}}{2} + \ln \left(\tan \frac{\pi}{8} \right) \right] \right). \end{aligned}$$

The equation of the tangent plane at that point is then

$$\left(9 - \frac{3\sqrt{6}}{2}\right)\left(x - \frac{3\sqrt{2}}{2}\right) + \left(9\sqrt{3} + \frac{3\sqrt{2}}{2}\right)\left(y - \frac{3\sqrt{6}}{2}\right) - 18\left(z - \left(\frac{\pi}{3} + 6\left[\frac{\sqrt{2}}{2} + \ln\left(\tan\frac{\pi}{8}\right)\right]\right)\right) = 0.$$

Using technology, that equation “simplifies” to

$$(6 - \sqrt{6})x + (\sqrt{2} + 6\sqrt{3})y - 12z = -4\pi - 72\ln(\tan(\sqrt{2} - 1)).$$

(c) The normal line has direction vector $\left\langle 9 - \frac{3\sqrt{6}}{2}, 9\sqrt{3} + \frac{3\sqrt{2}}{2}, -18 \right\rangle$ and passes through

$$\left(\frac{3\sqrt{2}}{2}, \frac{3\sqrt{6}}{2}, \frac{\pi}{3} + 6\left[\frac{\sqrt{2}}{2} + \ln(\tan(\sqrt{2} - 1))\right]\right),$$

so it has the parametrization

$$\begin{aligned} \mathbf{r}(t) = & \left(\frac{3\sqrt{2}}{2} + \left(9 - \frac{3\sqrt{6}}{2}\right)t\right) \mathbf{i} + \left(\frac{3\sqrt{6}}{2} + \left(9\sqrt{3} + \frac{3\sqrt{2}}{2}\right)t\right) \mathbf{j} \\ & + \left(\frac{\pi}{3} + 6\left[\frac{\sqrt{2}}{2} + \ln(\tan(\sqrt{2} - 1))\right] - 18t\right) \mathbf{k}. \end{aligned}$$

Challenge Problems

42. An annotated diagram of the triangle is

The line segment from B to C can be parametrized by

$$\mathbf{r}_1(t) = \langle b_1, b_2, b_3 \rangle + t \langle c_1 - b_1, c_2 - b_2, c_3 - b_3 \rangle, \quad 0 \leq t \leq 1.$$

Then if D is the point $\mathbf{r}(t_d)$, the line segment from A to D can be parametrized as

$$\begin{aligned} \mathbf{r}_2(u) &= \langle a_1, a_2, a_3 \rangle + u(\mathbf{r}_1(t_d) - \langle a_1, a_2, a_3 \rangle) \\ &= \langle a_1, a_2, a_3 \rangle + u(\langle b_1, b_2, b_3 \rangle + t_d \langle c_1 - b_1, c_2 - b_2, c_3 - b_3 \rangle - \langle a_1, a_2, a_3 \rangle) \\ &= (1 - u) \langle a_1, a_2, a_3 \rangle + u \langle b_1, b_2, b_3 \rangle + ut_d \langle c_1 - b_1, c_2 - b_2, c_3 - b_3 \rangle, \quad 0 \leq u \leq 1. \end{aligned}$$

Letting t range over all its values $0 \leq t \leq 1$, these line segments sweep out the triangle, so a parametrization is

$$\mathbf{r}(t, u) = (1 - u) \langle a_1, a_2, a_3 \rangle + u \langle b_1, b_2, b_3 \rangle + ut \langle c_1 - b_1, c_2 - b_2, c_3 - b_3 \rangle, \quad 0 \leq t \leq 1, \quad 0 \leq u \leq 1.$$

43. (a) Consider a circle of radius a and center $(b, 0, 0)$ lying in the xz -plane. Rotating that circle about the z -axis generates the required torus. Points on the circle are $(b + a \cos u, 0, a \sin u)$ for $0 \leq u \leq 2\pi$, so in cylindrical coordinates, the points on the circle are of the form

$$r = \sqrt{(b + a \cos u)^2 + 0^2} = b + a \cos u, \quad z = a \sin u, \quad \theta = 0, \quad 0 \leq u \leq 2\pi.$$

When the circle is rotated about the y -axis, the r and z coordinates of a given point on the circle remain constant, so a parametrization of the torus in cylindrical coordinates is

$$r = b + a \cos u, \quad z = a \sin u, \quad \theta = v, \quad 0 \leq u \leq 2\pi, \quad 0 \leq v \leq 2\pi.$$

In rectangular coordinates, this gives

$$\begin{aligned} x &= r \cos \theta = (b + a \cos u) \cos v \\ y &= r \sin \theta = (b + a \cos u) \sin v \\ z &= a \sin u, \end{aligned}$$

so that a parametrization of the torus in rectangular coordinates is

$$\mathbf{r}(u, v) = (b + a \cos u) \cos v \mathbf{i} + (b + a \cos u) \sin v \mathbf{j} + a \sin u \mathbf{k}.$$

- (b) To eliminate v , square and add the first two equations, giving

$$x^2 + y^2 = (b + a \cos u)^2 \cos^2 v + (b + a \cos u)^2 \sin^2 v = (b + a \cos u)^2.$$

To eliminate u , we need to get $a \cos u$ by itself so we can square this equation and the third and add them. So rewrite the above equation as

$$a \cos u = \sqrt{x^2 + y^2} - b;$$

then squaring this equation and adding it to the square of $z = a \sin u$ gives

$$a^2 \cos^2 u + a^2 \sin^2 u = z^2 + \left(\sqrt{x^2 + y^2} - b \right)^2, \quad \text{or}$$

$$z^2 + \left(\sqrt{x^2 + y^2} - b \right)^2 = a^2.$$

44. The surfaces involved are

The surface whose area we wish to find is the portion of the cylinder visible between the planes $z = 0$ and $z = 1$ on the right hand side of the diagram. To simplify things, note that this region is symmetric about the xz -plane, so we will compute the area for $y \geq 0$ and double it. Since the rectangular equation of the sphere is $x^2 + y^2 + z^2 = 4$, converting to cylindrical coordinates gives $r^2 + z^2 = 4$, or $z = \sqrt{4 - r^2}$. The cylinder lies above the circle $(x - 1)^2 + y^2 = 1$, which can be rewritten as $x^2 + y^2 - 2x = 0$. In cylindrical coordinates, this becomes $r^2 - 2r \cos \theta = 0$, or $r = 2 \cos \theta$ for $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. We want the portion of the cylinder lying outside (above) the sphere, so we require that $\sqrt{4 - r^2} \leq z \leq 1$. Substituting $2 \cos \theta$ for r gives the constraint $\sqrt{4 - 4 \cos^2 \theta} \leq z \leq 1$, or $|2 \sin \theta| \leq z \leq 1$. Since $\theta \geq 0$ when $y \geq 0$, we can write this as $2 \sin \theta \leq z \leq 1$, which implies that $0 \leq \theta \leq \frac{\pi}{6}$. We now have the bounds for the integration; next we must find the integrand. To do this, we find a rectangular parametrization of the circle $(x - 1)^2 + y^2 = 1$. From the above, we have $r^2 = x^2 + y^2 = 4 \cos^2 \theta$, so that

$$(x - 1)^2 + y^2 - 1 = x^2 + y^2 - 2x = 4 \cos^2 \theta - 2x = 0.$$

It follows that $x = 2 \cos^2 \theta = 1 + \cos(2\theta)$, so that

$$(x - 1)^2 + y^2 = \cos^2(2\theta) + y^2 = 1,$$

and therefore $y = \sin(2\theta)$. So a parametrization of the cylinder in rectangular coordinates is

$$\mathbf{r}(\theta, z) = \langle 1 + \cos(2\theta), \sin(2\theta), z \rangle.$$

Then

$$\mathbf{r}_\theta = \langle -2 \sin(2\theta), 2 \cos(2\theta), 0 \rangle, \quad \mathbf{r}_z = \langle 0, 0, 1 \rangle,$$

so that

$$\mathbf{r}_\theta \times \mathbf{r}_z = \langle -2 \sin(2\theta), 2 \cos(2\theta), 0 \rangle \times \langle 0, 0, 1 \rangle = \langle 2 \cos(2\theta), 2 \sin(2\theta), 0 \rangle.$$

Then $\|\mathbf{r}_\theta \times \mathbf{r}_z\| = \sqrt{4 \cos^2(2\theta) + 4 \sin^2(2\theta)} = 2$. Therefore the area of the region is (converting to cylindrical coordinates)

$$\begin{aligned} 2 \int_0^{\pi/6} \int_{2 \sin \theta}^1 2r \, dz \, d\theta &= 2 \int_0^{\pi/6} \int_{2 \sin \theta}^1 4 \cos \theta \, dz \, d\theta \\ &= 2 \int_0^{\pi/6} [4z \cos \theta]_{2 \sin \theta}^1 \, d\theta \\ &= 2 \int_0^{\pi/6} (4 \cos \theta - 8 \sin \theta \cos \theta) \, d\theta \\ &= 2 [4 \sin \theta - 4 \sin^2 \theta]_0^{\pi/6} \\ &= 2(2 - 1) = 2. \end{aligned}$$

45. The three surfaces are

The cone has rectangular equation $z = \sqrt{x^2 + y^2}$, since a cross-section at height $z = r$ gives $\sqrt{x^2 + y^2} = r$, so that $x^2 + y^2 = r^2$ and the cross-section is a circle of radius r . Using rectangular coordinates, we have

$$\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + \sqrt{u^2 + v^2}\mathbf{k}, \quad -r \leq u \leq r, \quad -\sqrt{1 - u^2} \leq v \leq \sqrt{1 - u^2}.$$

Then

$$\mathbf{r}_u = \mathbf{i} + u(u^2 + v^2)^{-1/2}\mathbf{k}, \quad \mathbf{r}_v = \mathbf{j} + v(u^2 + v^2)^{-1/2}\mathbf{k},$$

so that

$$\mathbf{r}_u \times \mathbf{r}_v = \langle 1, 0, u(u^2 + v^2)^{-1/2} \rangle \times \langle 0, 1, v(u^2 + v^2)^{-1/2} \rangle = \langle -u(u^2 + v^2)^{-1/2}, -v(u^2 + v^2)^{-1/2}, 1 \rangle,$$

and then

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\frac{u^2}{u^2 + v^2} + \frac{v^2}{u^2 + v^2} + 1} = \sqrt{\frac{2u^2 + 2v^2}{u^2 + v^2}} = \sqrt{2}.$$

Integrate using polar coordinates (ρ, θ) ; then $0 \leq \rho \leq r$ and $0 \leq \theta \leq 2\pi$, and we get for the surface area

$$\iint_R \|\mathbf{r}_u \times \mathbf{r}_v\| \, dA = \int_0^r \int_0^{2\pi} \rho\sqrt{2} \, d\theta \, dR = \int_0^r 2\pi\rho\sqrt{2} \, dR = \left[\pi\sqrt{2}\frac{\rho^2}{2} \right]_0^r = \pi r^2\sqrt{2}.$$

Parametrize the sphere using spherical coordinates, so that

$$\mathbf{r}(\theta, \phi) = r \cos \theta \sin \phi \mathbf{i} + r \sin \theta \sin \phi \mathbf{j} + r \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

Then

$$\mathbf{r}_\theta = -r \sin \theta \sin \phi \mathbf{i} + r \cos \theta \sin \phi \mathbf{j}, \quad \mathbf{r}_\phi = r \cos \theta \cos \phi \mathbf{i} + r \sin \theta \cos \phi \mathbf{j} - r \sin \phi \mathbf{k},$$

so that

$$\begin{aligned} \mathbf{r}_\theta \times \mathbf{r}_\phi &= \langle -r \sin \theta \sin \phi, r \cos \theta \sin \phi, 0 \rangle \times \langle r \cos \theta \cos \phi, r \sin \theta \cos \phi, -r \sin \phi \rangle \\ &= \langle -r^2 \cos \theta \cos^2 \phi, -r^2 \sin \theta \sin^2 \phi, -r^2 \sin \phi \cos \phi \rangle, \end{aligned}$$

and then

$$\|\mathbf{r}_\theta \times \mathbf{r}_\phi\| = r^2 \sin \phi.$$

Then the surface area is

$$\iint_R \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| \, dA = \int_0^{2\pi} \int_0^{\pi/2} r^2 \sin \phi \, d\phi \, d\theta = \int_0^{2\pi} [-r^2 \cos \phi]_0^{\pi/2} \, d\theta = \int_0^{2\pi} r^2 \, d\theta = 2\pi r^2.$$

Finally, parametrize the cylinder using cylindrical coordinates:

$$\mathbf{r}(\theta, z) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq r,$$

so that

$$\begin{aligned} \mathbf{r}_\theta \times \mathbf{r}_z &= \langle -r \sin \theta \sin \phi, r \cos \theta \cos \phi, 0 \rangle \times \langle 0, 0, 1 \rangle \\ &= \langle r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} \rangle, \end{aligned}$$

and then

$$\|\mathbf{r}_\theta \times \mathbf{r}_z\| = r.$$

Then the surface area is

$$\iint_R \|\mathbf{r}_\theta \times \mathbf{r}_z\| \, dA = \int_0^{2\pi} \int_0^r r \, dz \, d\theta = \int_0^{2\pi} [rz]_0^r \, d\theta = \int_0^{2\pi} r^2 \, d\theta = 2\pi r^2.$$

The ratios of the three surface areas are $\pi r^2\sqrt{2} : 2\pi r^2 : 2\pi r^2$, or $\sqrt{2} : 2 : 2$, as desired.

46. (a) The identity $\cosh^2 u - \sinh^2 u = 1$ is the key identity for this parametrization. We want $x^2 + y^2 - z^2 = c$, so we want to try to get $x^2 + y^2$ to equal $c \cosh^2 u$ and z^2 to equal $c \sinh^2 u$. The most natural way to do this is to let $z = \sqrt{c} \sinh u$ and then to introduce a new parameter v , with $x = \sqrt{c} \cosh u \cos v$ and $y = \sqrt{c} \cosh u \sin v$. Note that in the diagram in part (b), for a fixed value of z (that is, a fixed value of u), the cross-sections are circles, which is consistent with the parametrization of x and y above. With this parametrization, we have

$$\begin{aligned} x^2 + y^2 - z^2 &= (\sqrt{c} \cosh u \cos v)^2 + (\sqrt{c} \cosh u \sin v)^2 - (\sqrt{c} \sinh u)^2 \\ &= c (\cosh^2 u (\cos^2 v + \sin^2 v) - \sinh^2 u) \\ &= c (\cosh^2 u - \sinh^2 u) = c, \end{aligned}$$

as desired. So the parametrization is

$$\mathbf{r}(u, v) = \sqrt{c} \cosh u \cos v \mathbf{i} + \sqrt{c} \cosh u \sin v \mathbf{j} + \sqrt{c} \sinh u \mathbf{k}.$$

The bounds of the parameters are $-\infty < u < \infty$ and $0 \leq v \leq 2\pi$.

- (b) The one-sheeted hyperboloid from part (a) with $c = 1$ is

47. (a) First change variables, setting $x = ax'$, $y = by'$, and $z = cz'$. The hyperboloid then has the equation $(x')^2 - (y')^2 - (z')^2 = 1$ in the (x', y', z') coordinate system. The identity $\cosh^2 u - \sinh^2 u = 1$ is the key identity for this parametrization, as it was in Problem 46. We want $(x')^2 - (y')^2 - (z')^2 = 1$, so we want to try to get $(x')^2$ to equal $\cosh^2 u$ and $(y')^2 + (z')^2$ to equal $\sinh^2 u$. The most natural way to do this is to let $x' = \cosh u$ and then to introduce a new parameter v , with $y' = \sinh u \cos v$ and $z' = \sinh u \sin v$. With this parametrization, we have

$$\begin{aligned} (x')^2 - (y')^2 - (z')^2 &= \cosh^2 u - \sinh^2 u \cos^2 v - \sinh^2 u \sin^2 v \\ &= \cosh^2 u - \sinh^2 u (\cos^2 v + \sin^2 v) \\ &= \cosh^2 u - \sinh^2 u = 1, \end{aligned}$$

as desired. Substituting back in $\frac{x}{a}$ for x' , $\frac{y}{b}$ for y' , and $\frac{z}{c}$ for z' , we get

$$\begin{aligned} \frac{x}{a} &= \cosh u, & \frac{y}{b} &= \sinh u \cos v, & \frac{z}{c} &= \sinh u \sin v, \text{ or} \\ x &= a \cosh u, & y &= b \sinh u \cos v, & z &= c \sinh u \sin v. \end{aligned}$$

So the parametrization is

$$\mathbf{r}(u, v) = \boxed{a \cosh u \mathbf{i} + b \sinh u \cos v \mathbf{j} + c \sinh u \sin v \mathbf{k}}.$$

The bounds of the parameters are $-\infty < u < \infty$ and $0 \leq v \leq 2\pi$.

(b) The two-sheeted hyperboloid from part (a) with $a = 1$, $b = 2$, and $c = 3$ is

15.7: Surface and Flux Integrals

Concepts and Vocabulary

1. (c), *orientable*, is correct. See Objective 2.
2. (b), *flux*, is correct. See Objective 3.

Skill Building

3. Parametrize the surface by $x = u$ and $y = v$, so that

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + (2u + 3v + 5) \mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 2 \\ 0 & 1 & 3 \end{vmatrix} = -2 \mathbf{i} - 3 \mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{14}$, so the surface integral is

$$\begin{aligned} \iint_S (x^2 + y^2) dS &= \int_0^1 \int_0^1 (u^2 + v^2) \cdot \sqrt{14} du dv = \sqrt{14} \int_0^1 \left[\frac{1}{3} u^3 + uv^2 \right]_0^1 dv \\ &= \sqrt{14} \int_0^1 \left(\frac{1}{3} + v^2 \right) dv = \sqrt{14} \left[\frac{1}{3} v + \frac{1}{3} v^3 \right]_0^1 = \boxed{\frac{2}{3} \sqrt{14}}. \end{aligned}$$

4. Parametrize the surface by $x = u$ and $y = v$, so that

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + (3u + 4v + 8) \mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 3 \\ 0 & 1 & 4 \end{vmatrix} = -3\mathbf{i} - 4\mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{26}$, so the surface integral is

$$\begin{aligned} \iint_S x^2 y^2 dS &= \int_0^1 \int_0^1 u^2 v^2 \sqrt{26} du dv = \sqrt{26} \int_0^1 \left[\frac{1}{3} u^3 v^2 \right]_0^1 dv = \sqrt{26} \int_0^1 \left(\frac{1}{3} v^2 \right) dv \\ &= \sqrt{26} \left[\frac{1}{9} v^3 \right]_0^1 = \boxed{\frac{1}{9} \sqrt{26}}. \end{aligned}$$

5. Parametrize the surface by $x = u$ and $y = v$, so that

$$\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + (u + 5v^2)\mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 1 \\ 0 & 1 & 10v \end{vmatrix} = -1\mathbf{i} - 10v\mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{100v^2 + 2}$, so the surface integral is

$$\iint_S y dS = \int_0^1 \int_0^2 v \sqrt{100v^2 + 2} du dv = \int_0^1 \left[uv \sqrt{100v^2 + 2} \right]_0^2 dv = \int_0^1 2v \sqrt{100v^2 + 2} dv.$$

Use the substitution $t = 100v^2 + 2$, so that $dt = 200v dv$:

$$\int_0^1 2v \sqrt{100v^2 + 2} dv = \frac{1}{100} \int_2^{102} \sqrt{t} dt = \frac{1}{100} \left[\frac{2}{3} t^{3/2} \right]_2^{102} = \boxed{\frac{17}{25} \sqrt{102} - \frac{1}{75} \sqrt{2}}.$$

6. Parametrize the surface by $x = u$ and $y = v$, so that

$$\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + (2u^2 + v)\mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 4u \\ 0 & 1 & 1 \end{vmatrix} = -4u\mathbf{i} - 1\mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{16u^2 + 2}$, so the surface integral is

$$\iint_S 4x dS = \int_0^1 \int_0^2 4u \sqrt{16u^2 + 2} dv du = \int_0^1 \left[4uv \sqrt{16u^2 + 2} \right]_0^2 du = \int_0^1 8u \sqrt{u^2 + 2} du.$$

Use the substitution $t = 16u^2 + 2$, so that $dt = 32u du$:

$$\int_0^1 8u \sqrt{16u^2 + 2} du = \frac{1}{4} \int_2^{18} \sqrt{t} dt = \frac{1}{4} \left[\frac{2}{3} t^{3/2} \right]_2^{18} = \frac{1}{6} (18\sqrt{18} - 2\sqrt{2}) = \boxed{\frac{26}{3} \sqrt{2}}.$$

7. The region of interest in the xy -plane is

Parametrize the surface by $x = u$ and $y = v$, so that

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + (u - 3v) \mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 1 \\ 0 & 1 & -3 \end{vmatrix} = -1 \mathbf{i} + 3 \mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{11}$, so the surface integral is

$$\begin{aligned} \iint_S (x + y + z) dS &= \int_0^1 \int_0^{u/3} (u + v + u - 3v) \sqrt{11} dv du \\ &= \sqrt{11} \int_0^1 \int_0^{u/3} (2u - 2v) dv du \\ &= \sqrt{11} \int_0^1 [2uv - v^2]_0^{u/3} du \\ &= \sqrt{11} \int_0^1 \left(\frac{2}{3}u^2 - \frac{1}{9}u^2 \right) du \\ &= \sqrt{11} \int_0^1 \frac{5}{9}u^2 du \\ &= \sqrt{11} \left[\frac{5}{27}u^3 \right]_0^1 = \boxed{\frac{5}{27}\sqrt{11}}. \end{aligned}$$

8. The region in the xy -plane is a square of side 1 whose lower left corner is at the origin. Solve for z , giving $z = 2 - \frac{1}{2}x - \frac{1}{2}y$; then parametrize the surface by $x = u$ and $y = v$, so that

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + \left(2 - \frac{1}{2}u - \frac{1}{2}v \right) \mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -\frac{1}{2} \\ 0 & 1 & -\frac{1}{2} \end{vmatrix} = -\frac{1}{2} \mathbf{i} + \frac{1}{2} \mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\frac{1}{4} + \frac{1}{4} + 1} = \frac{\sqrt{6}}{2}$, so the surface integral is

$$\begin{aligned} \iint_S x dS &= \int_0^1 \int_0^1 u \cdot \frac{\sqrt{6}}{2} dv du \\ &= \frac{\sqrt{6}}{2} \int_0^1 [uv]_0^1 du \\ &= \frac{\sqrt{6}}{2} \int_0^1 u du \\ &= \frac{\sqrt{6}}{2} \left[\frac{1}{2}u^2 \right]_0^1 \\ &= \boxed{\frac{\sqrt{6}}{4}}. \end{aligned}$$

9. The region in the xy -plane is the disk of radius 1 inside the given cylinder. This suggests cylindrical coordinates, so parametrize the surface by $x = r \cos \theta$ and $y = r \sin \theta$, so that $z = 2 - r \cos \theta - r \sin \theta$. Therefore

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (2 - r \cos \theta - r \sin \theta) \mathbf{k}.$$

Then

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -\cos \theta - \sin \theta \\ -r \sin \theta & r \cos \theta & r \sin \theta - r \cos \theta \end{vmatrix} = r \mathbf{i} + r \mathbf{j} + r \mathbf{k}.$$

Therefore $\|\mathbf{r}_r \times \mathbf{r}_\theta\| = r\sqrt{3}$. The region of integration is over the unit circle, so that $0 \leq r \leq 1$ and $0 \leq \theta \leq 2\pi$. Then the surface integral is

$$\begin{aligned} \iint_S y \, dS &= \int_0^1 \int_0^{2\pi} r \sin \theta \cdot r\sqrt{3} \, d\theta \, dr \\ &= \sqrt{3} \int_0^1 \int_0^{2\pi} r^2 \sin \theta \, d\theta \, dr \\ &= \sqrt{3} \int_0^1 [-r^2 \cos \theta]_0^{2\pi} \, dr \\ &= \sqrt{3} \int_0^1 0 \, dr = \boxed{0}. \end{aligned}$$

10. The plane $x + 2y + 3z = 6$ intersects the xy -plane when $z = 0$, so along the line $x + 2y = 6$. The region in the xy -plane is therefore the region bounded by this line and the two coordinate axes:

Parametrize the surface by $x = u$, $y = v$, $z = \frac{1}{3}(6 - u - 2v) = 2 - \frac{1}{3}u - \frac{2}{3}v$, so that

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + \left(2 - \frac{1}{3}u - \frac{2}{3}v\right) \mathbf{k}.$$

Then

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -\frac{1}{3} \\ 0 & 1 & -\frac{2}{3} \end{vmatrix} = \frac{1}{3} \mathbf{i} + \frac{2}{3} \mathbf{j} + \mathbf{k}.$$

Therefore $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{\frac{1}{9} + \frac{4}{9} + 1} = \frac{\sqrt{14}}{3}$. The region is determined by $0 \leq y \leq 3$ and $0 \leq x \leq 6 - 2y$,

so the surface integral is

$$\begin{aligned}
 \iint_S yz \, dS &= \int_0^3 \int_0^{6-2v} v \left(2 - \frac{1}{3}u - \frac{2}{3}v \right) \cdot \frac{\sqrt{14}}{3} \, du \, dv \\
 &= \frac{\sqrt{14}}{3} \int_0^3 \int_0^{6-2v} \left(2v - \frac{1}{3}uv - \frac{2}{3}v^2 \right) \, du \, dv \\
 &= \frac{\sqrt{14}}{3} \int_0^3 \left[2uv - \frac{1}{6}u^2v - \frac{2}{3}uv^2 \right]_0^{6-2v} \\
 &= \frac{\sqrt{14}}{3} \int_0^3 \left(2(6-2v)v - \frac{1}{6}(6-2v)^2v - \frac{2}{3}(6-2v)v^2 \right) \, dv \\
 &= \frac{\sqrt{14}}{3} \int_0^3 \left(\frac{2}{3}v^3 - 4v^2 + 6v \right) \, dv \\
 &= \frac{\sqrt{14}}{3} \left[\frac{1}{6}v^4 - \frac{4}{3}v^3 + 3v^2 \right]_0^3 \\
 &= \frac{\sqrt{14}}{3} \left(\frac{27}{2} - 36 + 27 \right) = \boxed{\frac{3}{2}\sqrt{14}}.
 \end{aligned}$$

11. The surface is a cylinder of radius 1 and height 1. Parametrize the surface using cylindrical coordinates: $x = \cos \theta$, $y = \sin \theta$, $z = z$. Therefore

$$\mathbf{r}(\theta, z) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + z \mathbf{k}.$$

Then

$$\mathbf{r}_\theta \times \mathbf{r}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}.$$

Therefore $\|\mathbf{r}_\theta \times \mathbf{r}_z\| = \sqrt{\cos^2 \theta + \sin^2 \theta} = 1$. The region of integration is $0 \leq \theta \leq 2\pi$ and $0 \leq z \leq 1$, so that the surface integral is

$$\begin{aligned}
 \iint_S x^2 z \, dS &= \int_0^1 \int_0^{2\pi} \cos^2 \theta \cdot z \cdot 1 \, d\theta \, dz \\
 &= \int_0^1 \int_0^{2\pi} \left(\frac{1}{2} + \frac{1}{2} \cos 2\theta \right) z \, d\theta \, dz \\
 &= \int_0^1 \left[\left(\frac{1}{2}\theta + \frac{1}{4} \sin 2\theta \right) z \right]_0^{2\pi} \, dz \\
 &= \int_0^1 \pi z \, dz \\
 &= \left[\frac{1}{2} \pi z^2 \right]_0^1 = \boxed{\frac{\pi}{2}}.
 \end{aligned}$$

12. The surface is a cylinder of radius 3 and height 2. Parametrize the surface using cylindrical coordinates: $x = 3 \cos \theta$, $y = 3 \sin \theta$, $z = z$. Therefore

$$\mathbf{r}(\theta, z) = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j} + z \mathbf{k}.$$

Then

$$\mathbf{r}_\theta \times \mathbf{r}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3 \sin \theta & 3 \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j}.$$

Therefore $\|\mathbf{r}_\theta \times \mathbf{r}_z\| = \sqrt{9 \cos^2 \theta + 9 \sin^2 \theta} = 3$. The region of integration is $0 \leq \theta \leq 2\pi$ and $1 \leq z \leq 3$, so that the surface integral is

$$\begin{aligned} \iint_S (x+y)z \, dS &= \int_0^1 \int_0^{2\pi} (3 \cos \theta + 3 \sin \theta)z \, d\theta \, dz \\ &= 3 \int_0^1 [(\sin \theta - \cos \theta)z]_0^{2\pi} \, dz \\ &= 3 \int_0^1 0 \, dz = \boxed{0}. \end{aligned}$$

13. Since the surface is defined as $z = f(x, y) = \sqrt{16 - x^2 - y^2}$, the outer unit normal is the normal with a positive $\mathbf{k}$ component, which (see Objective 2) will be

$$\mathbf{n} = \frac{-f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k}}{\sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}}.$$

Here we have

$$\begin{aligned} f_x(x, y) &= \frac{1}{2} (16 - x^2 - y^2)^{-1/2} \cdot (-2x) = -\frac{x}{\sqrt{16 - x^2 - y^2}} \\ f_y(x, y) &= \frac{1}{2} (16 - x^2 - y^2)^{-1/2} \cdot (-2y) = -\frac{y}{\sqrt{16 - x^2 - y^2}}, \end{aligned}$$

so that

$$\begin{aligned} \mathbf{n} &= \frac{1}{\sqrt{\frac{x^2}{16 - x^2 - y^2} + \frac{y^2}{16 - x^2 - y^2} + 1}} \left(\frac{x}{\sqrt{16 - x^2 - y^2}} \mathbf{i} + \frac{y}{\sqrt{16 - x^2 - y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \frac{\sqrt{16 - x^2 - y^2}}{4} \left(\frac{x}{\sqrt{16 - x^2 - y^2}} \mathbf{i} + \frac{y}{\sqrt{16 - x^2 - y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \boxed{\frac{x}{4} \mathbf{i} + \frac{y}{4} \mathbf{j} + \frac{\sqrt{16 - x^2 - y^2}}{4} \mathbf{k}}. \end{aligned}$$

14. Since the surface is defined as $z = f(x, y) = \sqrt{1 - x^2 - y^2}$, the outer unit normal is the normal with a positive $\mathbf{k}$ component, which (see Objective 2) will be

$$\mathbf{n} = \frac{-f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k}}{\sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}}.$$

Here we have

$$\begin{aligned} f_x(x, y) &= \frac{1}{2} (1 - x^2 - y^2)^{-1/2} \cdot (-2x) = -\frac{x}{\sqrt{1 - x^2 - y^2}} \\ f_y(x, y) &= \frac{1}{2} (1 - x^2 - y^2)^{-1/2} \cdot (-2y) = -\frac{y}{\sqrt{1 - x^2 - y^2}}, \end{aligned}$$

so that

$$\begin{aligned} \mathbf{n} &= \frac{1}{\sqrt{\frac{x^2}{1 - x^2 - y^2} + \frac{y^2}{1 - x^2 - y^2} + 1}} \left(\frac{x}{\sqrt{1 - x^2 - y^2}} \mathbf{i} + \frac{y}{\sqrt{1 - x^2 - y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \sqrt{1 - x^2 - y^2} \left(\frac{x}{\sqrt{1 - x^2 - y^2}} \mathbf{i} + \frac{y}{\sqrt{1 - x^2 - y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \boxed{x \mathbf{i} + y \mathbf{j} + \sqrt{1 - x^2 - y^2} \mathbf{k}}. \end{aligned}$$

15. Since the surface is defined as $z = f(x, y) = \sqrt{36 - 9x^2 - 4y^2}$, the outer unit normal is the normal with a positive $\mathbf{k}$ component, which (see Objective 2) will be

$$\mathbf{n} = \frac{-f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k}}{\sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}}.$$

Here we have

$$\begin{aligned} f_x(x, y) &= \frac{1}{2} (36 - 9x^2 - 4y^2)^{-1/2} \cdot (-18x) = -\frac{9x}{\sqrt{36 - 9x^2 - 4y^2}} \\ f_y(x, y) &= \frac{1}{2} (36 - 9x^2 - 4y^2)^{-1/2} \cdot (-8y) = -\frac{4y}{\sqrt{36 - 9x^2 - 4y^2}}, \end{aligned}$$

so that

$$\begin{aligned} \mathbf{n} &= \frac{1}{\sqrt{\frac{81x^2}{36-9x^2-4y^2} + \frac{16y^2}{36-9x^2-4y^2} + 1}} \left(\frac{9x}{\sqrt{36-9x^2-4y^2}} \mathbf{i} + \frac{4y}{\sqrt{36-9x^2-4y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \frac{\sqrt{36-9x^2-4y^2}}{\sqrt{36+72x^2+12y^2}} \left(\frac{9x}{\sqrt{36-9x^2-4y^2}} \mathbf{i} + \frac{4y}{\sqrt{36-9x^2-4y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \frac{\sqrt{36-9x^2-4y^2}}{2\sqrt{9+18x^2+3y^2}} \left(\frac{9x}{\sqrt{36-9x^2-4y^2}} \mathbf{i} + \frac{4y}{\sqrt{36-9x^2-4y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \boxed{\frac{9x}{2\sqrt{9+18x^2+3y^2}} \mathbf{i} + \frac{4y}{2\sqrt{9+18x^2+3y^2}} \mathbf{j} + \frac{\sqrt{36-9x^2-4y^2}}{2\sqrt{9+18x^2+3y^2}} \mathbf{k}}. \end{aligned}$$

16. Since the surface is defined as $z = f(x, y) = \sqrt{4 - x^2 - 4y^2}$, the outer unit normal is the normal with a positive $\mathbf{k}$ component, which (see Objective 2) will be

$$\mathbf{n} = \frac{-f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k}}{\sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}}.$$

Here we have

$$\begin{aligned} f_x(x, y) &= \frac{1}{2} (4 - x^2 - 4y^2)^{-1/2} \cdot (-2x) = -\frac{x}{\sqrt{4 - x^2 - 4y^2}} \\ f_y(x, y) &= \frac{1}{2} (4 - x^2 - 4y^2)^{-1/2} \cdot (-8y) = -\frac{4y}{\sqrt{4 - x^2 - 4y^2}}, \end{aligned}$$

so that

$$\begin{aligned} \mathbf{n} &= \frac{1}{\sqrt{\frac{x^2}{4-x^2-4y^2} + \frac{16y^2}{4-x^2-4y^2} + 1}} \left(\frac{x}{\sqrt{4-x^2-4y^2}} \mathbf{i} + \frac{4y}{\sqrt{4-x^2-4y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \frac{\sqrt{4-x^2-4y^2}}{\sqrt{4+12y^2}} \left(\frac{x}{\sqrt{4-x^2-4y^2}} \mathbf{i} + \frac{4y}{\sqrt{4-x^2-4y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \frac{\sqrt{4-x^2-4y^2}}{2\sqrt{1+3y^2}} \left(\frac{x}{\sqrt{4-x^2-4y^2}} \mathbf{i} + \frac{4y}{\sqrt{4-x^2-4y^2}} \mathbf{j} + \mathbf{k} \right) \\ &= \boxed{\frac{x}{2\sqrt{1+3y^2}} \mathbf{i} + \frac{4y}{2\sqrt{1+3y^2}} \mathbf{j} + \frac{\sqrt{4-x^2-4y^2}}{2\sqrt{1+3y^2}} \mathbf{k}}. \end{aligned}$$

17. A normal vector is

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2u & 0 \\ 1 & 0 & 2v \end{vmatrix} = 4uv \mathbf{i} - 2v \mathbf{j} - 2u \mathbf{k}.$$

Then

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{(4uv)^2 + (-2v)^2 + (-2u)^2} = 2\sqrt{u^2 + 4uv + v^2},$$

so that the two unit normals are

$$\begin{aligned} \mathbf{n} &= \frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{4uv}{2\sqrt{u^2 + 4uv + v^2}} \mathbf{i} + \frac{-2v}{2\sqrt{u^2 + 4uv + v^2}} \mathbf{j} + \frac{-2u}{2\sqrt{u^2 + 4uv + v^2}} \mathbf{k} \\ -\mathbf{n} &= -\frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{-4uv}{2\sqrt{u^2 + 4uv + v^2}} \mathbf{i} + \frac{2v}{2\sqrt{u^2 + 4uv + v^2}} \mathbf{j} + \frac{2u}{2\sqrt{u^2 + 4uv + v^2}} \mathbf{k} \end{aligned}$$

18. A normal vector is

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ v & 0 & e^u \\ u & 1 & 0 \end{vmatrix} = -e^u \mathbf{i} + ue^u \mathbf{j} + v \mathbf{k}.$$

Then

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{(-e^u)^2 + (ue^u)^2 + v^2} = \sqrt{(u^2 + 1)e^{2u} + v^2},$$

so that the two unit normals are

$$\begin{aligned} \mathbf{n} &= \frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{1}{\sqrt{(u^2 + 1)e^{2u} + v^2}} (-e^u \mathbf{i} + ue^u \mathbf{j} + v \mathbf{k}) \\ -\mathbf{n} &= -\frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{1}{\sqrt{(u^2 + 1)e^{2u} + v^2}} (e^u \mathbf{i} - ue^u \mathbf{j} - v \mathbf{k}). \end{aligned}$$

19. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = x \mathbf{i}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$x \mathbf{i}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$x \mathbf{i}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$\mathbf{0}$	0	0
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$1 \mathbf{i}$	1	ρ
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$x \mathbf{i}$	0	0
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$x \mathbf{i}$	0	0

The only integral that has a nonzero integrand is S_4 ; for that integral, we get

$$\iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS = \rho \int_0^1 \int_0^1 dy dz = \rho.$$

So the total flux across the surface is $\boxed{\rho}$.

20. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = y \mathbf{i}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$y \mathbf{i}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$\mathbf{0}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$y \mathbf{i}$	$-y$	$-\frac{1}{2}\rho$
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$y \mathbf{i}$	y	$\frac{1}{2}\rho$
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$1 \mathbf{i}$	0	0
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$y \mathbf{i}$	0	0

Only S_3 and S_4 have nonzero integrands, and

$$\begin{aligned}\iint_{S_3} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 (-y) dy dz = \rho \int_0^1 \left[-\frac{1}{2}y^2 \right]_0^1 dz = -\frac{1}{2}\rho \int_0^1 1 dz = -\frac{1}{2}\rho \\ \iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 y dy dz = \rho \int_0^1 \left[\frac{1}{2}y^2 \right]_0^1 dz = \frac{1}{2}\rho \int_0^1 1 dz = \frac{1}{2}\rho.\end{aligned}$$

So the total flux across the surface is $\boxed{0}$.

21. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = z \mathbf{i}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$\mathbf{0}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$z \mathbf{i}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$z \mathbf{i}$	$-z$	$-\frac{1}{2}\rho$
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$z \mathbf{i}$	z	$\frac{1}{2}\rho$
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$z \mathbf{i}$	0	0
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$\mathbf{i}$	0	0

Only S_3 and S_4 have nonzero integrands, and

$$\begin{aligned}\iint_{S_3} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 (-z) dz dy = \rho \int_0^1 \left[-\frac{1}{2}z^2 \right]_0^1 dy = -\frac{1}{2}\rho \int_0^1 1 dy = -\frac{1}{2}\rho \\ \iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 z dz dy = \rho \int_0^1 \left[\frac{1}{2}z^2 \right]_0^1 dy = \frac{1}{2}\rho \int_0^1 1 dy = \frac{1}{2}\rho.\end{aligned}$$

So the total flux across the surface is $\boxed{0}$.

22. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = x \mathbf{i} + y \mathbf{j}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$x \mathbf{i} + y \mathbf{j}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$x \mathbf{i}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$y \mathbf{j}$	0	0
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$\mathbf{i} + y \mathbf{j}$	1	ρ
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$x \mathbf{i} + \mathbf{j}$	1	ρ
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$x \mathbf{i} + y \mathbf{j}$	0	0

Only S_4 and S_5 have nonzero integrands, so

$$\begin{aligned}\iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dy = \rho \int_0^1 [z]_0^1 dy = \rho \int_0^1 1 dy = \rho \\ \iint_{S_5} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dx = \rho \int_0^1 [z]_0^1 dx = \rho \int_0^1 1 dx = \rho.\end{aligned}$$

So the total flux across the surface is $\boxed{2\rho}$.

23. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = x \mathbf{i} + y \mathbf{j} + z \mathbf{k}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$x \mathbf{i} + y \mathbf{j}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$x \mathbf{i} + z \mathbf{k}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$y \mathbf{j} + z \mathbf{k}$	0	0
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$\mathbf{i} + y \mathbf{j} + z \mathbf{k}$	1	ρ
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$x \mathbf{i} + \mathbf{j} + z \mathbf{k}$	1	ρ
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$x \mathbf{i} + y \mathbf{j} + \mathbf{k}$	1	ρ

The values for S_4 , S_5 , and S_6 are determined as follows:

$$\begin{aligned}\iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dy = \rho \int_0^1 [z]_0^1 dy = \rho \int_0^1 1 dy = \rho \\ \iint_{S_5} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dx = \rho \int_0^1 [z]_0^1 dx = \rho \int_0^1 1 dx = \rho \\ \iint_{S_6} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dy dx = \rho \int_0^1 [y]_0^1 dx = \rho \int_0^1 1 dx = \rho.\end{aligned}$$

So the total flux across the surface is $\boxed{3\rho}$.

24. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = z^2 \mathbf{i}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$\mathbf{0}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$z^2 \mathbf{i}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$z^2 \mathbf{i}$	$-z^2$	$-\frac{1}{3}\rho$
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$z^2 \mathbf{i}$	z^2	$\frac{1}{3}\rho$
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$z^2 \mathbf{i}$	0	0
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$\mathbf{i}$	0	0

The values for S_3 and S_4 are determined as follows:

$$\begin{aligned}\iint_{S_3} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 (-z^2) dz dy = \rho \int_0^1 \left[-\frac{1}{3}z^3\right]_0^1 dy = \rho \int_0^1 \left(-\frac{1}{3}\right) dy = -\frac{1}{3}\rho \\ \iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 z^2 dz dx = \rho \int_0^1 \left[\frac{1}{3}z^3\right]_0^1 dx = \rho \int_0^1 \frac{1}{3} dx = \frac{1}{3}\rho.\end{aligned}$$

So the total flux across the surface is $\boxed{0}$.

25. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = x^2 \mathbf{i} + y^2 \mathbf{j} + z^2 \mathbf{k}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$x^2 \mathbf{i} + y^2 \mathbf{j}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$x^2 \mathbf{i} + z^2 \mathbf{k}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$y^2 \mathbf{j} + z^2 \mathbf{k}$	0	0
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$\mathbf{i} + y^2 \mathbf{j} + z^2 \mathbf{k}$	1	ρ
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$x^2 \mathbf{i} + \mathbf{j} + z^2 \mathbf{k}$	1	ρ
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$x^2 \mathbf{i} + y^2 \mathbf{j} + \mathbf{k}$	1	ρ

The values for S_4 , S_5 , and S_6 are determined as follows:

$$\begin{aligned}\iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dy = \rho \int_0^1 [z]_0^1 dy = \rho \int_0^1 1 dy = \rho \\ \iint_{S_5} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dx = \rho \int_0^1 [z]_0^1 dx = \rho \int_0^1 1 dx = \rho \\ \iint_{S_6} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dy dx = \rho \int_0^1 [y]_0^1 dx = \rho \int_0^1 1 dx = \rho.\end{aligned}$$

So the total flux across the surface is $\boxed{3\rho}$.

26. Using the notation in Example 8 and Figure 66, we construct a similar table, with $\mathbf{F}(x, y, z) = x^2 \mathbf{i} + y^2 \mathbf{j}$:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$	$\rho \iint_S \mathbf{F} \cdot \mathbf{n} dS$
$S_1 = ABCO$ $z = 0$	$-\mathbf{k}$	$x^2 \mathbf{i} + y^2 \mathbf{j}$	0	0
$S_2 = OAEG$ $y = 0$	$-\mathbf{j}$	$x^2 \mathbf{i}$	0	0
$S_3 = OCDG$ $x = 0$	$-\mathbf{i}$	$y^2 \mathbf{j}$	0	0
$S_4 = ABFE$ $x = 1$	$\mathbf{i}$	$\mathbf{i} + y^2 \mathbf{j}$	1	ρ
$S_5 = BCDF$ $y = 1$	$\mathbf{j}$	$x^2 \mathbf{i} + \mathbf{j}$	1	ρ
$S_6 = DFEG$ $z = 1$	$\mathbf{k}$	$x^2 \mathbf{i} + y^2 \mathbf{j}$	0	0

The values for S_4 and S_5 are determined as follows:

$$\begin{aligned} \iint_{S_4} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dy = \rho \int_0^1 [z]_0^1 dy = \rho \int_0^1 1 dy = \rho \\ \iint_{S_5} \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^1 \int_0^1 1 dz dx = \rho \int_0^1 [z]_0^1 dx = \rho \int_0^1 1 dx = \rho. \end{aligned}$$

So the total flux across the surface is $\boxed{2\rho}$.

Applications and Extensions

27. The surface is the upper hemisphere of the unit sphere. Parametrizing using spherical coordinates, we get

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

Then

$$\mathbf{r}_\theta \times \mathbf{r}_\phi = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \end{vmatrix} = -\cos \theta \sin^2 \phi \mathbf{i} - \sin \theta \sin^2 \phi \mathbf{j} - \cos \phi \sin \phi \mathbf{k}.$$

We want the outward normal, so we use instead

$$-(\mathbf{r}_\theta \times \mathbf{r}_\phi) = \cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \cos \phi \sin \phi \mathbf{k}.$$

Then with $\mathbf{F} = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}$ the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} dS &= \int_0^{2\pi} \int_0^{\pi/2} \mathbf{F} \cdot \frac{\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \cos \phi \sin \phi \mathbf{k}}{\|\mathbf{r}_\theta \times \mathbf{r}_\phi\|} \cdot \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (\cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}) \cdot (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \cos \phi \sin \phi \mathbf{k}) d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (\cos^2 \theta \sin^3 \phi + \sin^2 \theta \sin^3 \phi + \sin \phi \cos^2 \phi) d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (\sin^3 \phi + \sin \phi \cos^2 \phi) d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (\sin \phi (\sin^2 \phi + \cos^2 \phi)) d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} \sin \phi d\phi d\theta \\ &= \int_0^{2\pi} [-\cos \phi]_0^{\pi/2} d\theta = \int_0^{2\pi} 1 d\theta = \boxed{2\pi}. \end{aligned}$$

28. The surface is the upper hemisphere of the unit sphere. Parametrizing using spherical coordinates, we get

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

Then

$$\mathbf{r}_\theta \times \mathbf{r}_\phi = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \end{vmatrix} = -\cos \theta \sin^2 \phi \mathbf{i} - \sin \theta \sin^2 \phi \mathbf{j} - \cos \phi \sin \phi \mathbf{k}.$$

We want the outward normal, so we use instead

$$-(\mathbf{r}_\theta \times \mathbf{r}_\phi) = \cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \cos \phi \sin \phi \mathbf{k}.$$

Then with $\mathbf{F} = -y \mathbf{i} + x \mathbf{j} + z \mathbf{k} = -\sin \theta \sin \phi \mathbf{i} + \cos \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}$ the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} dS &= \int_0^{2\pi} \int_0^{\pi/2} \mathbf{F} \cdot \frac{\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \cos \phi \sin \phi \mathbf{k}}{\|\mathbf{r}_\theta \times \mathbf{r}_\phi\|} \cdot \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (-\sin \theta \sin \phi \mathbf{i} + \cos \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}) \cdot (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \cos \phi \sin \phi \mathbf{k}) d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (-\sin \theta \cos \theta \sin^3 \phi + \sin \theta \cos \theta \sin^3 \phi + \sin \phi \cos^2 \phi) d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} \sin \phi \cos^2 \phi d\phi d\theta \\ &= \int_0^{2\pi} \left[-\frac{1}{3} \cos^3 \phi \right]_0^{\pi/2} d\theta = \boxed{\frac{2}{3}\pi}. \end{aligned}$$

29. The region in the xy -plane over which this surface lies is determined by setting $z = 0$ in the equation, giving $2x + 2y = 8$, or $y = 4 - x$; this line, together with the x and y -axes, bounds the region:

Therefore the region of integration will be $0 \leq x \leq 4$, $0 \leq y \leq 4 - x$. Parametrize the surface by $x = u$, $y = v$, $z = 8 - 2u - 2v$. Then

$$\mathbf{r}(u, v) = u \mathbf{i} + v \mathbf{j} + (8 - 2u - 2v) \mathbf{k},$$

so that

$$\mathbf{r}_u = \mathbf{i} - 2\mathbf{k}, \quad \mathbf{r}_v = \mathbf{j} - 2\mathbf{k}.$$

Therefore

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -2 \\ 0 & 1 & -2 \end{vmatrix} = 2\mathbf{i} + 2\mathbf{j} + \mathbf{k}.$$

Then $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{2^2 + 2^2 + 1^2} = 3$; since the $\mathbf{k}$ -component of the cross product is positive, this is the normal we want. So the unit normal is

$$\mathbf{n} = \frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{1}{3}(2\mathbf{i} + 2\mathbf{j} + \mathbf{k}).$$

The vector field is

$$\mathbf{F} = (x+y)\mathbf{i} + (2x-z)\mathbf{j} + y\mathbf{k} = (u+v)\mathbf{i} + (2u - (8-2u-2v))\mathbf{j} + v\mathbf{k} = (u+v)\mathbf{i} + (4u+2v-8)\mathbf{j} + v\mathbf{k}.$$

It follows that the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^4 \int_0^{4-u} ((u+v)\mathbf{i} + (4u+2v-8)\mathbf{j} + v\mathbf{k}) \cdot \left(\frac{1}{3}(2\mathbf{i} + 2\mathbf{j} + \mathbf{k})\right) \cdot 3 \, dv \, du \\ &= \int_0^4 \int_0^{4-u} ((u+v)\mathbf{i} + (4u+2v-8)\mathbf{j} + v\mathbf{k}) \cdot (2\mathbf{i} + 2\mathbf{j} + \mathbf{k}) \, dv \, du \\ &= \int_0^4 \int_0^{4-u} (2(u+v) + 2(4u+2v-8) + v) \, dv \, du \\ &= \int_0^4 \int_0^{4-u} (10u + 7v - 16) \, dv \, du \\ &= \int_0^4 \left[10uv + \frac{7}{2}v^2 - 16v \right]_0^{4-u} \, du \\ &= \int_0^4 \left(10u(4-u) + \frac{7}{2}(4-u)^2 - 16(4-u) \right) \, du \\ &= \int_0^4 \left(-\frac{13}{2}u^2 + 28u - 8 \right) \, du \\ &= \left[-\frac{13}{6}u^3 + 14u^2 - 8u \right]_0^4 = \boxed{\frac{160}{3}}. \end{aligned}$$

30. The region in the xy -plane over which this surface lies is determined by setting $z = 0$ in the equation, giving $2x + 2y = 6$, or $y = 3 - x$; this line, together with the x and y -axes, bounds the region:

Therefore the region of integration will be $0 \leq x \leq 3$, $0 \leq y \leq 3 - x$. Parametrize the surface by $x = u$, $y = v$, $z = 6 - 2u - 2v$. Then

$$\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + (6 - 2u - 2v)\mathbf{k},$$

so that

$$\mathbf{r}_u = \mathbf{i} - 2\mathbf{k}, \quad \mathbf{r}_v = \mathbf{j} - 2\mathbf{k}.$$

Therefore

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -2 \\ 0 & 1 & -2 \end{vmatrix} = 2\mathbf{i} + 2\mathbf{j} + \mathbf{k}.$$

Then $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{2^2 + 2^2 + 1^2} = 3$; since the $\mathbf{k}$ -component of the cross product is positive, this is the normal we want. So the unit normal is

$$\mathbf{n} = \frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{1}{3}(2\mathbf{i} + 2\mathbf{j} + \mathbf{k}).$$

The vector field is

$$\mathbf{F} = 2x\mathbf{i} - x^2\mathbf{j} + (z - 2x + 2y)\mathbf{k} = 2u\mathbf{i} - u^2\mathbf{j} + (6 - 2u - 2v - 2u + 2v)\mathbf{k} = 2u\mathbf{i} - u^2\mathbf{j} + (6 - 4u)\mathbf{k}.$$

It follows that the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^3 \int_0^{3-u} (2u\mathbf{i} - u^2\mathbf{j} + (6 - 4u)\mathbf{k}) \cdot \left(\frac{1}{3}(2\mathbf{i} + 2\mathbf{j} + \mathbf{k})\right) \cdot 3 \, dv \, du \\ &= \int_0^3 \int_0^{3-u} (2u\mathbf{i} - u^2\mathbf{j} + (6 - 4u)\mathbf{k}) \cdot (2\mathbf{i} + 2\mathbf{j} + \mathbf{k}) \, dv \, du \\ &= \int_0^3 \int_0^{3-u} (4u - 2u^2 + 6 - 4u) \, dv \, du \\ &= \int_0^3 \int_0^{3-u} (6 - 2u^2) \, dv \, du \\ &= \int_0^3 (6 - 2u^2)(3 - u) \, du \\ &= \int_0^3 (2u^3 - 6u^2 - 6u + 18) \, du \\ &= \left[\frac{1}{2}u^4 - 2u^3 - 3u^2 + 18u \right]_0^3 = \boxed{\frac{27}{2}}. \end{aligned}$$

31. The surface is

Differentiating gives

$$\mathbf{r}_u = v\mathbf{i} + 2u\mathbf{j}, \quad \mathbf{r}_v = u\mathbf{i} + \mathbf{k}.$$

Therefore

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ v & 2u & 0 \\ u & 0 & 1 \end{vmatrix} = 2u\mathbf{i} - v\mathbf{j} - 2u^2\mathbf{k}.$$

We can choose either orientation; we choose the one given by this normal vector (if we choose the other orientation, we will get the negative of the answer below). Then $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{4u^2 + v^2 + 4u^4}$. So the unit normal is

$$\mathbf{n} = \frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{1}{\sqrt{4u^2 + v^2 + 4u^4}}(2u\mathbf{i} - v\mathbf{j} - 2u^2\mathbf{k}).$$

The vector field is

$$\mathbf{F} = -z\mathbf{j} + \mathbf{k} = -v\mathbf{j} + \mathbf{k}.$$

It follows that the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} dS &= \int_1^2 \int_0^3 (-v\mathbf{j} + \mathbf{k}) \cdot \frac{1}{\sqrt{4u^2 + v^2 + 4u^4}} (2u\mathbf{i} - v\mathbf{j} - 2u^2\mathbf{k}) \cdot \sqrt{4u^2 + v^2 + 4u^4} dv du \\ &= \int_1^2 \int_0^3 (-v\mathbf{j} + \mathbf{k}) \cdot (2u\mathbf{i} - v\mathbf{j} - 2u^2\mathbf{k}) dv du \\ &= \int_1^2 \int_0^3 (v^2 - 2u^2) dv du \\ &= \int_1^2 \left[\frac{1}{3}v^3 - 2u^2v \right]_0^3 du \\ &= \int_1^2 (9 - 6u^2) du \\ &= [9u - 2u^3]_1^2 = \boxed{-5}. \end{aligned}$$

32. The surface is

Differentiating gives

$$\mathbf{r}_u = ve^u\mathbf{i} + \mathbf{k}, \quad \mathbf{r}_v = e^u\mathbf{i} + 3v^2\mathbf{j}.$$

Therefore

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ ve^u & 0 & 1 \\ e^u & 3v^2 & 0 \end{vmatrix} = -3v^2\mathbf{i} + e^u\mathbf{j} + 3e^uv^3\mathbf{k}.$$

We can choose either orientation; we choose the one given by this normal vector (if we choose the other orientation, we will get the negative of the answer below). Then $\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{9v^4 + e^{2u}(1 + 9v^6)}$. So the unit normal is

$$\mathbf{n} = \frac{\mathbf{r}_u \times \mathbf{r}_v}{\|\mathbf{r}_u \times \mathbf{r}_v\|} = \frac{1}{\sqrt{9v^4 + e^{2u}(1 + 9v^6)}} (-3v^2\mathbf{i} + e^u\mathbf{j} + 3e^uv^3\mathbf{k}).$$

The vector field is

$$\mathbf{F} = xy\mathbf{i} + 2z\mathbf{j} = v^4e^u\mathbf{i} + 2u\mathbf{j}.$$

It follows that the flux is

$$\begin{aligned}
 \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^1 \int_{-1}^1 (v^4 e^u \mathbf{i} + 2u \mathbf{j}) \cdot \frac{1}{\sqrt{9v^4 + e^{2u}(1 + 9v^6)}} (-3v^2 \mathbf{i} + e^u \mathbf{j} + 3e^u v^3 \mathbf{k}) \\
 &\quad \cdot \sqrt{9v^4 + e^{2u}(1 + 9v^6)} \, dv \, du \\
 &= \int_0^1 \int_{-1}^1 (v^4 e^u \mathbf{i} + 2u \mathbf{j}) \cdot (-3v^2 \mathbf{i} + e^u \mathbf{j} + 3e^u v^3 \mathbf{k}) \, dv \, du \\
 &= \int_0^1 \int_{-1}^1 (-3v^6 e^u + 2ue^u) \, dv \, du \\
 &= \int_0^1 \left[-\frac{3}{7} v^7 e^u + 2uv e^u \right]_{-1}^1 \, du \\
 &= \int_0^1 \left(4ue^u - \frac{6}{7} e^u \right) \, du.
 \end{aligned}$$

To integrate ue^u , use integration by parts with $r = u$ and $ds = e^u du$; then $dr = du$ and $s = e^u$, so we get

$$\begin{aligned}
 &= 4 \int_0^1 ue^u \, du - \frac{6}{7} \int_0^1 e^u \, du \\
 &= 4 \left([ue^u]_0^1 - \int_0^1 e^u \, du \right) - \frac{6}{7} \int_0^1 e^u \, du \\
 &= 4e - \frac{34}{7} \int_0^1 e^u \, du \\
 &= 4e - \frac{34}{7} [e^u]_0^1 = \boxed{-\frac{6}{7}e + \frac{34}{7}}.
 \end{aligned}$$

33. The surface is

Parametrize using cylindrical coordinates; the equation of the cone is $z = r$. Then the range $2 \leq z \leq 4$ corresponds to $2 \leq r \leq 4$, so the parametrization is

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + r \mathbf{k}.$$

Differentiating gives

$$\mathbf{r}_r = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + \mathbf{k}, \quad \mathbf{r}_\theta = -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j}.$$

Therefore

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 1 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = -r \cos \theta \mathbf{i} - r \sin \theta \mathbf{j} + r \mathbf{k}.$$

Then $\|\mathbf{r}_r \times \mathbf{r}_\theta\| = \sqrt{r^2 \cos^2 \theta + r^2 \sin^2 \theta + r^2} = r\sqrt{2}$. The mass density of the lamina is $\rho = 8 - z = 8 - r$, so the mass of the lamina is

$$\begin{aligned} M &= \iint_S \rho \, dS = \iint_R \rho \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, dr \, d\theta \\ &= \iint_R (8 - r) \cdot r\sqrt{2} \, dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \int_2^4 (8r - r^2) \, dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \left[4r^2 - \frac{1}{3}r^3 \right]_2^4 \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \frac{88}{3} \, d\theta = \boxed{\frac{176}{3} \pi \sqrt{2}}. \end{aligned}$$

34. The surface is the same as in Problem 33, so the parametrization is the same:

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + r \mathbf{k},$$

as is $\|\mathbf{r}_r \times \mathbf{r}_\theta\| = \sqrt{r^2 \cos^2 \theta + r^2 \sin^2 \theta + r^2} = r\sqrt{2}$. See Problem 33 for details. The mass density of the lamina is $\rho = \sqrt{x^2 + y^2} = \sqrt{r^2} = r$, so the mass of the lamina is

$$\begin{aligned} M &= \iint_S \rho \, dS = \iint_R \rho \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, dr \, d\theta \\ &= \iint_R r \cdot r\sqrt{2} \, dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \int_2^4 r^2 \, dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \left[\frac{1}{3}r^3 \right]_2^4 \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \frac{56}{3} \, d\theta = \boxed{\frac{112}{3} \pi \sqrt{2}}. \end{aligned}$$

35. The surface is

Parametrize using a variant of cylindrical coordinates:

$$x = r \cos \theta, \quad y = y, \quad z = r \sin \theta.$$

Then since $y = \frac{1}{3}(4 - 2x - z)$, the equation of the plane is

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + \frac{1}{3}(4 - 2r \cos \theta - r \sin \theta) \mathbf{j} + r \sin \theta \mathbf{k}.$$

Then

$$\mathbf{r}_r = \cos \theta \mathbf{i} + \frac{1}{3}(-2 \cos \theta - \sin \theta) \mathbf{j} + \sin \theta \mathbf{k}, \quad \mathbf{r}_\theta = -r \sin \theta \mathbf{i} + \frac{1}{3}(2r \sin \theta - r \cos \theta) \mathbf{j} + r \cos \theta \mathbf{k},$$

so that

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \frac{1}{3}(-2 \cos \theta - \sin \theta) & \sin \theta \\ -r \sin \theta & \frac{1}{3}(2r \sin \theta - r \cos \theta) & r \cos \theta \end{vmatrix} = -\frac{2r}{3} \mathbf{i} - r \mathbf{j} - \frac{r}{3} \mathbf{k}.$$

Then

$$\|\mathbf{r}_r \times \mathbf{r}_\theta\| = \sqrt{\frac{4r^2}{9} + r^2 + \frac{r^2}{9}} = r \frac{\sqrt{14}}{3}.$$

Since we want the portion of the plane lying inside the cylinder $x^2 + z^2 = r^2 = 9$, the region describing that portion of the plane is $0 \leq r \leq 3$, $0 \leq \theta \leq 2\pi$. Also, the mass density of the lamina is $\rho = \sqrt{x^2 + z^2} = \sqrt{r^2} = r$.

Then the mass of the lamina is

$$\begin{aligned}
 M &= \iint_S \rho \, dS = \iint_R \rho \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, dr \, d\theta \\
 &= \iint_R r \cdot r \frac{\sqrt{14}}{3} \, dr \, d\theta \\
 &= \frac{\sqrt{14}}{3} \int_0^{2\pi} \int_0^3 r^2 \, dr \, d\theta \\
 &= \frac{\sqrt{14}}{3} \int_0^{2\pi} \left[\frac{1}{3} r^3 \right]_0^3 \, d\theta \\
 &= \frac{\sqrt{14}}{3} \int_0^{2\pi} 9 \, d\theta = 6\pi\sqrt{14}.
 \end{aligned}$$

The moments are

$$\begin{aligned}
 M_{xy} &= \iint_S \rho z \, dS = \iint_R \rho r \sin \theta \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, dr \\
 &= \iint_R r \cdot r \sin \theta \cdot r \frac{\sqrt{14}}{3} \, d\theta \, dr \\
 &= \frac{\sqrt{14}}{3} \int_0^3 \int_0^{2\pi} r^3 \sin \theta \, d\theta \, dr \\
 &= \frac{\sqrt{14}}{3} \int_0^3 [-r^3 \cos \theta]_0^{2\pi} \, dr = 0 \\
 M_{yz} &= \iint_S \rho x \, dS = \iint_R \rho r \cos \theta \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, dr \\
 &= \iint_R r \cdot r \cos \theta \cdot r \frac{\sqrt{14}}{3} \, d\theta \, dr \\
 &= \frac{\sqrt{14}}{3} \int_0^3 \int_0^{2\pi} r^3 \cos \theta \, d\theta \, dr \\
 &= \frac{\sqrt{14}}{3} \int_0^3 [r^3 \sin \theta]_0^{2\pi} \, dr = 0 \\
 M_{xz} &= \iint_S \rho y \, dS = \iint_R \rho \left(\frac{1}{3}(4 - 2r \cos \theta - r \sin \theta) \right) \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, dr \\
 &= \frac{1}{3} \iint_R r(4 - 2r \cos \theta - r \sin \theta) \cdot r \frac{\sqrt{14}}{3} \, d\theta \, dr \\
 &= \frac{\sqrt{14}}{9} \int_0^3 \int_0^{2\pi} (4r^2 - 2r^3 \cos \theta - r^3 \sin \theta) \, d\theta \, dr \\
 &= \frac{\sqrt{14}}{9} \int_0^3 [4r^2\theta - 2r^3 \sin \theta + r^3 \cos \theta]_0^{2\pi} \, dr \\
 &= \frac{\sqrt{14}}{9} \int_0^3 8\pi r^2 \, dr \\
 &= \frac{\sqrt{14}}{9} \left[\frac{8}{3} \pi r^3 \right]_0^3 = 8\pi\sqrt{14}.
 \end{aligned}$$

The center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(\frac{M_{yz}}{M}, \frac{M_{xz}}{M}, \frac{M_{xy}}{M} \right) = \boxed{\left(0, \frac{4}{3}, 0 \right)}.$$

36. Parametrize the unit sphere using spherical coordinates, so that

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}.$$

Then

$$\mathbf{r}_\theta = -\sin \theta \sin \phi \mathbf{i} + \cos \theta \sin \phi \mathbf{j}, \quad \mathbf{r}_\phi = \cos \theta \cos \phi \mathbf{i} + \sin \theta \cos \phi \mathbf{j} - \sin \phi \mathbf{k},$$

so that

$$\mathbf{r}_\theta \times \mathbf{r}_\phi = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \end{vmatrix} = -\cos \theta \sin^2 \phi \mathbf{i} - \sin \theta \sin^2 \phi \mathbf{j} - \cos \phi \sin \phi \mathbf{k}.$$

Then

$$\begin{aligned} \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| &= \sqrt{\cos^2 \theta \sin^4 \phi + \sin^2 \theta \sin^4 \phi + \cos^2 \phi \sin^2 \phi} \\ &= \sqrt{(\cos^2 \theta + \sin^2 \theta) \sin^4 \phi + \cos^2 \phi \sin^2 \phi} \\ &= \sqrt{(\sin^2 \phi + \cos^2 \phi) \sin^2 \phi} = \sin \phi \end{aligned}$$

since $0 \leq \phi \leq \pi$ and $\sin \phi \geq 0$ there. The mass density of the lamina is $\rho = z + 1 = 1 + \cos \phi$.

Therefore the mass of the lamina is

$$\begin{aligned} M &= \iint_S \rho \, dS = \iint_R \rho \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, d\phi \\ &= \iint_R (1 + \cos \phi) \sin \phi \, d\theta \, d\phi \\ &= \int_0^\pi \int_0^{2\pi} (\sin \phi + \cos \phi \sin \phi) \, d\theta \, d\phi \\ &= 2\pi \int_0^\pi (\sin \phi + \cos \phi \sin \phi) \, d\phi \\ &= 2\pi \left[-\cos \phi + \frac{1}{2} \sin^2 \phi \right]_0^\pi = 4\pi. \end{aligned}$$

The moments are

$$\begin{aligned} M_{xy} &= \iint_S \rho z \, dS = \iint_R \rho \cos \phi \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, d\phi \\ &= \int_0^\pi \int_0^{2\pi} (1 + \cos \phi) \cos \phi \sin \phi \, d\theta \, d\phi \\ &= \int_0^\pi \int_0^{2\pi} (\cos \phi \sin \phi + \cos^2 \phi \sin \phi) \, d\theta \, d\phi \\ &= 2\pi \int_0^\pi (\cos \phi \sin \phi + \cos^2 \phi \sin \phi) \, d\phi \\ &= 2\pi \left[\frac{1}{2} \sin^2 \phi - \frac{1}{3} \cos^3 \phi \right]_0^\pi = \frac{4}{3} \pi \end{aligned}$$

$$\begin{aligned}
M_{yz} &= \iint_S \rho x \, dS = \iint_R \rho \cos \theta \sin \phi \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, d\phi \\
&= \int_0^\pi \int_0^{2\pi} (1 + \cos \phi) \cos \theta \sin \phi \sin \phi \, d\theta \, d\phi \\
&= \int_0^\pi \int_0^{2\pi} \cos \theta (\sin^2 \phi + \cos \phi \sin^2 \phi) \, d\theta \, d\phi \\
&= \int_0^\pi [\sin \theta (\sin^2 \phi + \cos \phi \sin^2 \phi)]_0^{2\pi} \, d\phi \\
&= \int_0^\pi 0 \, d\phi = 0
\end{aligned}$$

$$\begin{aligned}
M_{xz} &= \iint_S \rho y \, dS = \iint_R \rho \sin \theta \sin \phi \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, d\phi \\
&= \int_0^\pi \int_0^{2\pi} (1 + \cos \phi) \sin \theta \sin \phi \sin \phi \, d\theta \, d\phi \\
&= \int_0^\pi \int_0^{2\pi} \sin \theta (\sin^2 \phi + \cos \phi \sin^2 \phi) \, d\theta \, d\phi \\
&= \int_0^\pi [-\cos \theta (\sin^2 \phi + \cos \phi \sin^2 \phi)]_0^{2\pi} \, d\phi \\
&= \int_0^\pi 0 \, d\phi = 0.
\end{aligned}$$

The center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(\frac{M_{yz}}{M}, \frac{M_{xz}}{M}, \frac{M_{xy}}{M} \right) = \boxed{\left(0, 0, \frac{1}{3} \right)}.$$

37. Parametrize the cylinder using cylindrical coordinates; then

$$x = 3 \cos \theta, \quad y = 3 \sin \theta, \quad z = z, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq 5.$$

Then

$$\mathbf{r}(\theta, z) = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j} + z \mathbf{k},$$

so that

$$\mathbf{r}_\theta = -3 \sin \theta \mathbf{i} + 3 \cos \theta \mathbf{j}, \quad \mathbf{r}_z = \mathbf{k}.$$

Then

$$\begin{aligned}
\mathbf{r}_\theta \times \mathbf{r}_z &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3 \sin \theta & 3 \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j} \\
\|\mathbf{r}_\theta \times \mathbf{r}_z\| &= \sqrt{9 \cos^2 \theta + 9 \sin^2 \theta} = 3.
\end{aligned}$$

Then the surface integral is

$$\begin{aligned}
 \iint_S x^2 z \, dS &= \iint_R (3 \cos \theta)^2 \cdot z \cdot 3 \, dz \, d\theta \\
 &= \int_0^{2\pi} \int_0^5 27z \cos^2 \theta \, dz \, d\theta \\
 &= \int_0^{2\pi} \left[\frac{27}{2} z^2 \cos^2 \theta \right]_0^5 d\theta \\
 &= \frac{675}{2} \int_0^{2\pi} \cos^2 \theta \, d\theta \\
 &= \frac{675}{2} \int_0^{2\pi} \left(\frac{1}{2} + \frac{1}{2} \cos(2\theta) \right) d\theta \\
 &= \frac{675}{2} \left[\frac{1}{2} \theta + \frac{1}{4} \sin(2\theta) \right]_0^{2\pi} = \boxed{\frac{675}{2} \pi}.
 \end{aligned}$$

38. With the given parametrization, we have

$$\mathbf{r}_u = \cos v \mathbf{i} + 2u \mathbf{j} + \cos v \mathbf{k}, \quad \mathbf{r}_v = -u \sin v \mathbf{i} - u \sin v \mathbf{k}.$$

Then

$$\begin{aligned}
 \mathbf{r}_u \times \mathbf{r}_v &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos v & 2u & \cos v \\ -u \sin v & 0 & -u \sin v \end{vmatrix} = -2u^2 \sin v \mathbf{i} + 2u^2 \sin v \mathbf{k} \\
 \|\mathbf{r}_u \times \mathbf{r}_v\| &= \sqrt{4u^4 \sin^2 v + 4u^4 \sin^2 v} = 2u^2 \sqrt{2} \sin v.
 \end{aligned}$$

Then the surface integral is

$$\begin{aligned}
 \iint_S (x + 2y) \, dS &= \iint_R (u \cos v + 2(u^2 + 1)) \cdot 2u^2 \sqrt{2} \sin v \, dv \, du \\
 &= \sqrt{2} \int_0^1 \int_0^{\pi/2} (2u^3 \cos v \sin v + 4u^2(u^2 + 1) \sin v) \, dv \, du \\
 &= \sqrt{2} \int_0^1 \left[2u^3 \cdot \frac{1}{2} \sin^2 v + 4u^2(u^2 + 1)(-\cos v) \right]_0^{\pi/2} du \\
 &= \sqrt{2} \int_0^1 (u^3 + 4u^2(u^2 + 1)) \, du \\
 &= \sqrt{2} \int_0^1 (4u^4 + u^3 + 4u^2) \, du \\
 &= \sqrt{2} \left[\frac{4}{5} u^5 + \frac{1}{4} u^4 + \frac{4}{3} u^3 \right]_0^1 \\
 &= \boxed{\frac{143}{60} \sqrt{2}}.
 \end{aligned}$$

39. The surface is

Parametrize the surface using cylindrical coordinates; then $z = r^2$ and we have

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + r^2 \mathbf{k}.$$

Differentiating gives

$$\mathbf{r}_r = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + 2r \mathbf{k}, \quad \mathbf{r}_\theta = -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j}.$$

Therefore

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 2r \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = -2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}.$$

We use this as the outward (upward) normal, so that

$$\mathbf{n} = \frac{\mathbf{r}_r \times \mathbf{r}_\theta}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} = \frac{-2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|}.$$

The vector field is

$$\mathbf{F} = -x \mathbf{i} - y \mathbf{j} - z \mathbf{k} = -r \cos \theta \mathbf{i} - r \sin \theta \mathbf{j} - r^2 \mathbf{k}.$$

Let the mass density of the fluid be ρ . It follows that the flux is

$$\begin{aligned} \iint_S \rho \mathbf{F} \cdot \mathbf{n} dS &= \rho \int_0^{2\pi} \int_0^{\sqrt{5}} (-r \cos \theta \mathbf{i} - r \sin \theta \mathbf{j} - r^2 \mathbf{k}) \cdot \frac{-2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| dr d\theta \\ &= \rho \int_0^{2\pi} \int_0^{\sqrt{5}} (-r \cos \theta \mathbf{i} - r \sin \theta \mathbf{j} - r^2 \mathbf{k}) \cdot (-2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) dr d\theta \\ &= \rho \int_0^{2\pi} \int_0^{\sqrt{5}} (2r^3 \cos^2 \theta + 2r^3 \sin^2 \theta - r^3) dr d\theta \\ &= \rho \int_0^{2\pi} \int_0^{\sqrt{5}} r^3 dr d\theta \\ &= \rho \int_0^{2\pi} \left[\frac{1}{4} r^4 \right]_0^{\sqrt{5}} d\theta \\ &= \rho \int_0^{2\pi} \frac{25}{4} d\theta = \boxed{\frac{25}{2} \pi \rho}. \end{aligned}$$

40. The surface is

Parametrize the surface using cylindrical coordinates; then $z = 9 - r^2$ and we have

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (9 - r^2) \mathbf{k}.$$

Differentiating gives

$$\mathbf{r}_r = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} - 2r \mathbf{k}, \quad \mathbf{r}_\theta = -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j}.$$

Therefore

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -2r \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = 2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}.$$

We use this as the outward (upward) normal, so that

$$\mathbf{n} = \frac{\mathbf{r}_r \times \mathbf{r}_\theta}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} = \frac{2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|}.$$

The vector field is

$$\mathbf{F} = x \mathbf{i} + y \mathbf{j} + 3 \mathbf{k} = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + 3 \mathbf{k}.$$

It follows that the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^{2\pi} \int_0^3 (r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + 3 \mathbf{k}) \cdot \frac{2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^3 (r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + 3 \mathbf{k}) \cdot (2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^3 (2r^3 \cos^2 \theta + 2r^3 \sin^2 \theta + 3r) \, dr \, d\theta \\ &= \int_0^{2\pi} \int_0^3 (2r^3 + 3r) \, dr \, d\theta \\ &= \int_0^{2\pi} \left[\frac{1}{2} r^4 + \frac{3}{2} r^2 \right]_0^3 \, d\theta \\ &= \int_0^{2\pi} 54 \, d\theta = \boxed{108\pi}. \end{aligned}$$

41. From equation (3) in Objective 2, the upward pointing normal $\mathbf{n}$ to $z = f(x, y)$ is

$$\mathbf{n} = \frac{-f_x(x, y) \mathbf{i} - f_y(x, y) \mathbf{j} + \mathbf{k}}{\sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}}.$$

Use the natural parametrization of the surface $x = x$, $y = y$, $z = f(x, y)$; then

$$\begin{aligned}\mathbf{r}(x, y) &= x\mathbf{i} + y\mathbf{j} + f(x, y)\mathbf{k} \\ \mathbf{r}_x &= \mathbf{i} + f_x(x, y)\mathbf{k}, \quad \mathbf{r}_y = \mathbf{j} + f_y(x, y)\mathbf{k} \\ \mathbf{r}_x \times \mathbf{r}_y &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & f_x(x, y) \\ 0 & 1 & f_y(x, y) \end{vmatrix} = -f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k} \\ \|\mathbf{r}_x \times \mathbf{r}_y\| &= \sqrt{(-f_x(x, y))^2 + (-f_y(x, y))^2 + 1} = \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}.\end{aligned}$$

Therefore the integral is

$$\begin{aligned}\iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \iint_D (P\mathbf{i} + Q\mathbf{j} + R\mathbf{k}) \cdot \frac{-f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k}}{\sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}} \\ &\quad \cdot \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1} \, dx \, dy \\ &= \iint_D (P\mathbf{i} + Q\mathbf{j} + R\mathbf{k}) \cdot (-f_x(x, y)\mathbf{i} - f_y(x, y)\mathbf{j} + \mathbf{k}) \, dx \, dy \\ &= \iint_D (-Pf_x(x, y) - Qf_y(x, y) + R) \, dx \, dy \\ &= \iint_D \left(-P\frac{\partial f}{\partial x} - Q\frac{\partial f}{\partial y} + R \right) \, dx \, dy.\end{aligned}$$

42. Parametrizing the cylinder using cylindrical coordinates gives

$$\mathbf{r}(\theta, z) = 3\cos\theta\mathbf{i} + 3\sin\theta\mathbf{j} + z\mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq 2.$$

Then

$$\begin{aligned}\mathbf{r}_\theta &= -3\sin\theta\mathbf{i} + 3\cos\theta\mathbf{j}, \quad \mathbf{r}_z = \mathbf{k} \\ \mathbf{r}_\theta \times \mathbf{r}_z &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3\sin\theta & 3\cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = 3\cos\theta\mathbf{i} + 3\sin\theta\mathbf{j} \\ \|\mathbf{r}_\theta \times \mathbf{r}_z\| &= 3.\end{aligned}$$

It follows that the flux is

$$\begin{aligned}\iint_S \mathbf{E} \cdot \mathbf{n} \, dS &= \int_0^{2\pi} \int_0^3 (3\cos\theta\mathbf{i} + 2 \cdot 3\sin\theta\mathbf{j} + 3z\mathbf{k}) \cdot \frac{3\cos\theta\mathbf{i} + 3\sin\theta\mathbf{j}}{3} \cdot 3 \, dz \, d\theta \\ &= \int_0^{2\pi} \int_0^3 (3\cos\theta\mathbf{i} + 6\sin\theta\mathbf{j} + 3z\mathbf{k}) \cdot (3\cos\theta\mathbf{i} + 3\sin\theta\mathbf{j}) \, dz \, d\theta \\ &= \int_0^{2\pi} \int_0^3 (9\cos^2\theta + 18\sin^2\theta) \, dz \, d\theta \\ &= 27 \int_0^{2\pi} (\cos^2\theta + 2\sin^2\theta) \, d\theta \\ &= 27 \int_0^{2\pi} \left(\frac{1}{2} + \frac{1}{2}\cos(2\theta) + 1 - \cos(2\theta) \right) \, d\theta \\ &= 27 \int_0^{2\pi} \left(\frac{3}{2} - \frac{1}{2}\cos(2\theta) \right) \, d\theta \\ &= 27 \left[\frac{3}{2}\theta - \frac{1}{4}\sin(2\theta) \right]_0^{2\pi} = \boxed{81\pi}.\end{aligned}$$

43. Given the parametrization, we have

$$\begin{aligned}\mathbf{r}_u &= \cos(2v)\mathbf{i} + \sin(2v)\mathbf{j}, & \mathbf{r}_v &= -2u\sin(2v)\mathbf{i} + 2u\cos(2v)\mathbf{j} + \mathbf{k} \\ \mathbf{r}_u \times \mathbf{r}_v &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos(2v) & \sin(2v) & 0 \\ -2u\sin(2v) & 2u\cos(2v) & 1 \end{vmatrix} = \sin(2v)\mathbf{i} - \cos(2v)\mathbf{j} + 2u\mathbf{k} \\ \|\mathbf{r}_\theta \times \mathbf{r}_z\| &= \sqrt{4u^2 + 1}.\end{aligned}$$

Then the surface integral is

$$\begin{aligned}\iint_S (x^2 + z^2) dS &= \int_0^3 \int_0^{2\pi} (u^2 \cos^2(2v) + v^2) \cdot \sqrt{4u^2 + 1} dv du \\ &= \int_0^3 \int_0^{2\pi} \left(u^2 \left(\frac{1}{2} + \frac{1}{2} \cos(4v) \right) + v^2 \right) \cdot \sqrt{4u^2 + 1} dv du \\ &= \int_0^3 \left[\frac{1}{2} u^2 v + \frac{1}{8} u^2 \sin(4v) + \frac{1}{3} v^3 \right]_0^{2\pi} \sqrt{4u^2 + 1} du \\ &= \int_0^3 \left(\pi u^2 + \frac{8}{3} \pi^3 \right) \sqrt{4u^2 + 1} du \\ &= \pi \int_0^3 u^2 \sqrt{4u^2 + 1} du + \frac{8}{3} \pi^3 \int_0^3 \sqrt{4u^2 + 1} du.\end{aligned}$$

For both integrals use the substitution $t = 2u$, so that $dt = 2 du$; then $u = 0$ corresponds to $t = 0$ and $u = 3$ to $t = 6$. We get

$$\begin{aligned}&= \frac{\pi}{2} \int_0^6 \left(\frac{t}{2} \right)^2 \sqrt{t^2 + 1} dt + \frac{4}{3} \pi^3 \int_0^6 \sqrt{t^2 + 1} dt \\ &= \frac{\pi}{8} \int_0^6 t^2 \sqrt{t^2 + 1} dt + \frac{4}{3} \pi^3 \int_0^6 \sqrt{t^2 + 1} dt\end{aligned}$$

Now use Formulas 49 and 51 from the integral formulas in the Endsheets, giving

$$\begin{aligned}&= \frac{\pi}{8} \left[\frac{t}{8} (2t^2 + 1) \sqrt{t^2 + 1} - \frac{1}{8} \ln |t + \sqrt{t^2 + 1}| \right]_0^6 \\ &\quad + \frac{4}{3} \pi^3 \left[\frac{t}{2} \sqrt{t^2 + 1} + \frac{1}{2} \ln |t + \sqrt{t^2 + 1}| \right]_0^6 \\ &= \frac{\pi}{8} \left(\frac{3}{4} \cdot 73 \cdot \sqrt{37} - \frac{1}{8} \ln(6 + \sqrt{37}) \right) + \frac{4}{3} \pi^3 \left(3\sqrt{37} + \frac{1}{2} \ln(6 + \sqrt{37}) \right) \\ &= \boxed{\left(\frac{219}{32} \pi + 4\pi^3 \right) \sqrt{37} + \left(\frac{2}{3} \pi^3 - \frac{1}{64} \pi \right) \ln(6 + \sqrt{37})}.\end{aligned}$$

Challenge Problems

44. Since both the surface and the density function are symmetric with respect to the x and y coordinates, we have $\bar{x} = \bar{y} = 0$, so we need only compute $\bar{z}$. Parametrize the hemisphere using spherical coordinates:

$$x = a \cos \theta \sin \phi, \quad y = a \sin \theta \sin \phi, \quad z = a \cos \phi, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2},$$

so that

$$\mathbf{r}(\theta, \phi) = a \cos \theta \sin \phi \mathbf{i} + a \sin \theta \sin \phi \mathbf{j} + a \cos \phi \mathbf{k}.$$

Then

$$\mathbf{r}_\theta = -a \sin \theta \sin \phi \mathbf{i} + a \cos \theta \sin \phi \mathbf{j}, \quad \mathbf{r}_\phi = a \cos \theta \cos \phi \mathbf{i} + a \sin \theta \cos \phi \mathbf{j} - a \sin \phi \mathbf{k},$$

so that

$$\mathbf{r}_\theta \times \mathbf{r}_\phi = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -a \sin \theta \sin \phi & a \cos \theta \sin \phi & 0 \\ a \cos \theta \cos \phi & a \sin \theta \cos \phi & -a \sin \phi \end{vmatrix} = -a^2 \cos \theta \sin^2 \phi \mathbf{i} - a^2 \sin \theta \sin^2 \phi \mathbf{j} - a^2 \cos \phi \sin \phi \mathbf{k}.$$

Then

$$\begin{aligned} \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| &= \sqrt{a^4 \cos^2 \theta \sin^4 \phi + a^4 \sin^2 \theta \sin^4 \phi + a^4 \cos^2 \phi \sin^2 \phi} \\ &= a^2 \sqrt{(\cos^2 \theta + \sin^2 \theta) \sin^4 \phi + \cos^2 \phi \sin^2 \phi} \\ &= a^2 \sqrt{(\sin^2 \phi + \cos^2 \phi) \sin^2 \phi} = a^2 \sin \phi \end{aligned}$$

since $0 \leq \phi \leq \frac{\pi}{2}$ and $\sin \phi \geq 0$ there. The mass density of the lamina is the distance from the xy -plane, which is just the z -coordinate, so that $\rho = z = \cos \phi$.

Therefore the mass of the lamina is

$$\begin{aligned} M &= \iint_S \rho \, dS = \iint_R \rho \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, d\phi \\ &= \iint_R \cos \phi \cdot a^2 \sin \phi \, d\theta \, d\phi \\ &= a^2 \int_0^{\pi/2} \int_0^{2\pi} \cos \phi \sin \phi \, d\theta \, d\phi \\ &= 2\pi a^2 \int_0^{\pi/2} \cos \phi \sin \phi \, d\phi \\ &= 2\pi a^2 \left[\frac{1}{2} \sin^2 \phi \right]_0^{\pi/2} = \pi a^2. \end{aligned}$$

The xy moment is

$$\begin{aligned} M_{xy} &= \iint_S \rho z \, dS = \iint_R \rho a \cos \phi \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, d\phi \\ &= \int_0^{\pi/2} \int_0^{2\pi} \cos \phi \cdot a \cos \phi \cdot a^2 \sin \phi \, d\theta \, d\phi \\ &= a^3 \int_0^{\pi/2} \int_0^{2\pi} \cos^2 \phi \sin \phi \, d\theta \, d\phi \\ &= 2\pi a^3 \int_0^{\pi/2} \cos^2 \phi \sin \phi \, d\phi \\ &= 2\pi a^3 \left[-\frac{1}{3} \cos^3 \phi \right]_0^{\pi/2} = \frac{2}{3} \pi a^3. \end{aligned}$$

The center of mass is

$$(\bar{x}, \bar{y}, \bar{z}) = \left(\frac{M_{yz}}{M}, \frac{M_{xz}}{M}, \frac{M_{xy}}{M} \right) = \boxed{\left(0, 0, \frac{2a}{3} \right)}.$$

45. Suppose the level surface S is $f(x, y, z) = a$ for some constant a . Then

$$\mathbf{F} = \nabla f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} + \frac{\partial f}{\partial z} \mathbf{k}.$$

But from The Gradient is Normal to the Level Curve Theorem in Section 13.1, generalized to one additional dimension, we see that ∇f is normal to the level curve of $w = f(x, y, z)$ at each point, so

that ∇f is also a normal vector. Since

$$\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2 + \left(\frac{\partial f}{\partial z}\right)^2 = 1,$$

it follows that $\|\nabla f\| = 1$, so that ∇f is a unit normal. Then

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iint_S (\nabla f) \cdot (\nabla f) \, dS = \iint_S \left(\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2 + \left(\frac{\partial f}{\partial z}\right)^2 \right) dS = \iint_S 1 \, dS,$$

which is just the area of S .

15.8: The Divergence Theorem

Concepts and Vocabulary

1. False. $\operatorname{div} \mathbf{F}$ is a function; see the definition at the start of the section.
2. $\operatorname{div} \mathbf{F} = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}$; see the definition at the start of the section.

Skill Building

3. We have $\operatorname{div} \mathbf{F} = \operatorname{div}(x^2 \mathbf{i} + y^2 \mathbf{j} + z^2 \mathbf{j}) = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(z^2) = \boxed{2x + 2y + 2z}$.
4. We have $\operatorname{div} \mathbf{F} = \operatorname{div}(x \mathbf{i} + xy \mathbf{j} + xyz \mathbf{j}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(xy) + \frac{\partial}{\partial z}(xyz) = \boxed{1 + x + xy}$.
5. We have

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \operatorname{div}((x + \cos x) \mathbf{i} + (y + y \sin x) \mathbf{j} + 2z \mathbf{j}) \\ &= \frac{\partial}{\partial x}(x + \cos x) + \frac{\partial}{\partial y}(y + y \sin x) + \frac{\partial}{\partial z}(2z) = 1 - \sin x + 1 + \sin x + 2 = \boxed{4}. \end{aligned}$$

6. We have

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \operatorname{div}(xye^z \mathbf{i} + x^2e^z \mathbf{j} + x^2ye^z \mathbf{j}) \\ &= \frac{\partial}{\partial x}(xye^z) + \frac{\partial}{\partial y}(x^2e^z) + \frac{\partial}{\partial z}(x^2ye^z) = ye^z + 0 + x^2ye^z = \boxed{(1 + x^2)ye^z}. \end{aligned}$$

7. We have

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \operatorname{div}(\sqrt{x^2 + y^2} \mathbf{i} + \sqrt{x^2 + y^2} \mathbf{j} + z \mathbf{j}) = \frac{\partial}{\partial x}(\sqrt{x^2 + y^2}) + \frac{\partial}{\partial y}(\sqrt{x^2 + y^2}) + \frac{\partial}{\partial z}(z) \\ &= \frac{1}{2}(x^2 + y^2)^{-1/2} \cdot 2x + \frac{1}{2}(x^2 + y^2)^{-1/2} \cdot 2y + 1 = \boxed{\frac{x + y}{\sqrt{x^2 + y^2}} + 1}. \end{aligned}$$

8. We have

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \operatorname{div}(xy^2 \mathbf{i} + x^2y \mathbf{j} + xyz \mathbf{j}) \\ &= \frac{\partial}{\partial x}(xy^2) + \frac{\partial}{\partial y}(x^2y) + \frac{\partial}{\partial z}(xyz) = y^2 + x^2 + xy = \boxed{x^2 + xy + y^2}. \end{aligned}$$

9. The surface is

Compute $\operatorname{div} \mathbf{F}$:

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(2xy + 2z) + \frac{\partial}{\partial y}(y^2 + 1) + \frac{\partial}{\partial z}(-(x + y)) = 2y + 2y = 4y.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E 4y \, dx \, dy \, dz$$

where E is the interior of the given surface. This solid is given by $0 \leq x \leq 4$, $0 \leq y \leq 4 - x$, $0 \leq z \leq 4 - x - y$, so that

$$\begin{aligned} \iiint_E 4y \, dx \, dy \, dz &= \int_0^4 \int_0^{4-x} \int_0^{4-x-y} 4y \, dz \, dy \, dx \\ &= \int_0^4 \int_0^{4-x} [4yz]_0^{4-x-y} \, dy \, dx \\ &= \int_0^4 \int_0^{4-x} 4y(4-x-y) \, dy \, dx \\ &= \int_0^4 \int_0^{4-x} (16y - 4xy - 4y^2) \, dy \, dx \\ &= \int_0^4 \left[8y^2 - 2xy^2 - \frac{4}{3}y^3 \right]_0^{4-x} \, dx \\ &= \int_0^4 \left(8(4-x)^2 - 2x(4-x)^2 - \frac{4}{3}(4-x)^3 \right) \, dx \\ &= \int_0^4 \left(-\frac{2}{3}x^3 + 8x^2 - 32x + \frac{128}{3} \right) \, dx \\ &= \left[-\frac{1}{6}x^4 + \frac{8}{3}x^3 - 16x^2 + \frac{128}{3}x \right]_0^4 \\ &= \boxed{\frac{128}{3}}. \end{aligned}$$

10. The surface is

Compute $\operatorname{div} \mathbf{F}$:

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(2xy + z) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(-(x + 4y)) = 2y + 2y = 4y.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E 4y \, dx \, dy \, dz$$

where E is the interior of the given surface. This solid is given by $0 \leq x \leq 3$, $0 \leq y \leq 3 - x$, $0 \leq z \leq 6 - 2x - 2y$, so that

$$\begin{aligned} \iiint_E 4y \, dx \, dy \, dz &= \int_0^3 \int_0^{3-x} \int_0^{6-2x-2y} 4y \, dz \, dy \, dx \\ &= \int_0^3 \int_0^{3-x} [4yz]_0^{6-2x-2y} \, dy \, dx \\ &= \int_0^3 \int_0^{3-x} 4y(6 - 2x - 2y) \, dy \, dx \\ &= \int_0^3 \int_0^{3-x} (24y - 8xy - 8y^2) \, dy \, dx \\ &= \int_0^3 \left[12y^2 - 4xy^2 - \frac{8}{3}y^3 \right]_0^{3-x} \, dx \\ &= \int_0^3 \left(12(3-x)^2 - 4x(3-x)^2 - \frac{8}{3}(3-x)^3 \right) \, dx \\ &= \int_0^3 \left(-\frac{4}{3}x^3 + 12x^2 - 36x + 36 \right) \, dx \\ &= \left[-\frac{1}{3}x^4 + 4x^3 - 18x^2 + 36x \right]_0^3 \\ &= \boxed{27}. \end{aligned}$$

11. The given solid is the unit cube, and

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(z^2) = 2x + 2y + 2z.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \iiint_E (2x + 2y + 2z) dx dy dz$$

where E is the interior of the given surface. This solid is given by $0 \leq x \leq 1$, $0 \leq y \leq 1$, $0 \leq z \leq 1$, so that

$$\begin{aligned} \iiint_E (2x + 2y + 2z) dx dy dz &= \int_0^1 \int_0^1 \int_0^1 (2x + 2y + 2z) dx dy dz \\ &= \int_0^1 \int_0^1 [x^2 + 2xy + 2xz]_0^1 dy dz \\ &= \int_0^1 \int_0^1 (2y + 2z + 1) dy dz \\ &= \int_0^1 [y^2 + 2yz + y]_0^1 dz \\ &= \int_0^1 (2z + 2) dz \\ &= [z^2 + 2z]_0^1 = \boxed{3}. \end{aligned}$$

12. We have

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x - y) + \frac{\partial}{\partial y}(y - z) + \frac{\partial}{\partial z}(x - y) = 2.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \iiint_E 2 dx dy dz$$

where E is the interior of the given surface. This is twice the volume of the solid; since the solid is a cube whose side length is 2, it has volume 8, so

$$\iiint_E 2 dx dy dz = \boxed{16}.$$

13. We have

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(2y) + \frac{\partial}{\partial z}(4z^2) = 2x + 8z + 2.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \iiint_E (2x + 8z + 2) dx dy dz$$

where E is the interior of the given surface. Convert to cylindrical coordinates to compute the integral; then $x = r \cos \theta$, $y = r \sin \theta$, $z = z$ for $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$, and $0 \leq z \leq 2$. We get

$$\begin{aligned} \iiint_E (2x + 8z + 2) dx dy dz &= \int_0^2 \int_0^{2\pi} \int_0^2 (2r \cos \theta + 8z + 2) \cdot r dz d\theta dr \\ &= \int_0^2 \int_0^{2\pi} [2r^2 z \cos \theta + 4rz^2 + 2rz]_0^2 d\theta dr \\ &= \int_0^2 \int_0^{2\pi} (4r^2 \cos \theta + 20r) d\theta dr \\ &= \int_0^2 [4r^2 \sin \theta + 20r\theta]_0^{2\pi} dr \\ &= \int_0^2 40r\pi dr \\ &= [20r^2\pi]_0^2 = \boxed{80\pi}. \end{aligned}$$

14. We have

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(2y^2) + \frac{\partial}{\partial z}(3z^2) = 4y + 6z + 1.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E (4y + 6z + 1) \, dx \, dy \, dz$$

where E is the interior of the given surface. Convert to cylindrical coordinates to compute the integral; then $x = r \cos \theta$, $y = r \sin \theta$, $z = z$ for $0 \leq r \leq 3$, $0 \leq \theta \leq 2\pi$, and $0 \leq z \leq 1$. We get

$$\begin{aligned} \iiint_E (4y + 6z + 1) \, dx \, dy \, dz &= \int_0^3 \int_0^{2\pi} \int_0^1 (4r \cos \theta + 6z + 1) \cdot r \, dz \, d\theta \, dr \\ &= \int_0^3 \int_0^{2\pi} [4r^2 z \cos \theta + 3rz^2 + rz]_0^1 \, d\theta \, dr \\ &= \int_0^3 \int_0^{2\pi} (4r^2 \cos \theta + 4r) \, d\theta \, dr \\ &= \int_0^3 [4r^2 \sin \theta + 4r\theta]_0^{2\pi} \, dr \\ &= \int_0^3 8r\pi \, dr \\ &= [4r^2\pi]_0^3 = \boxed{36\pi}. \end{aligned}$$

15. We have

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 1 + 1 + 1 = 3.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E 3 \, dx \, dy \, dz$$

where E is the interior of the given sphere. The volume of a sphere of radius 1 is $\frac{4}{3}\pi$, and this integral is three times that volume, so

$$\iiint_E 3 \, dx \, dy \, dz = \boxed{4\pi}.$$

16. We have

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(2x) + \frac{\partial}{\partial y}(2y) + \frac{\partial}{\partial z}(2z) = 2 + 2 + 2 = 6.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E 6 \, dx \, dy \, dz$$

where E is the interior of the given sphere. The volume of a sphere of radius $\sqrt{2}$ is $\frac{4}{3}\pi \cdot 2\sqrt{2} = \frac{8}{3}\pi\sqrt{2}$, and this integral is six times that volume, so

$$\iiint_E 6 \, dx \, dy \, dz = 6 \cdot \frac{8}{3}\pi\sqrt{2} = \boxed{16\pi\sqrt{2}}.$$

17. The surface is

Compute $\operatorname{div} \mathbf{F}$:

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x + \cos x) + \frac{\partial}{\partial y}(y + y \sin x) + \frac{\partial}{\partial z}(2z) = 1 - \sin x + 1 + \sin x + 2 = 4.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E 4 \, dx \, dy \, dz$$

where E is the interior of the given surface. This solid is given by $0 \leq x \leq 1$, $0 \leq y \leq 1 - x$, $0 \leq z \leq 1 - x - y$, so that

$$\begin{aligned} \iiint_E 4 \, dx \, dy \, dz &= \int_0^1 \int_0^{1-x} \int_0^{1-x-y} 4 \, dz \, dy \, dx \\ &= \int_0^1 \int_0^{1-x} [4z]_0^{1-x-y} \, dy \, dx \\ &= \int_0^1 \int_0^{1-x} (4 - 4x - 4y) \, dy \, dx \\ &= \int_0^1 [4y - 4xy - 2y^2]_0^{1-x} \, dx \\ &= \int_0^1 (4(1-x) - 4x(1-x) - 2(1-x)^2) \, dx \\ &= \int_0^1 (2x^2 - 4x + 2) \, dx \\ &= \left[\frac{2}{3}x^3 - 2x^2 + 2x \right]_0^1 = \boxed{\frac{2}{3}}. \end{aligned}$$

Alternatively, if you recall that the volume of a pyramid is $\frac{1}{3}$ times the area of the base times the height, the result follows without integration since $4 \cdot \frac{1}{3} \cdot \frac{1}{2} \cdot 1 = \frac{2}{3}$.

18. A plot of the surface is given in Problem 17. Compute $\operatorname{div} \mathbf{F}$:

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(yz) + \frac{\partial}{\partial y}(xz) + \frac{\partial}{\partial z}(xy) = 0.$$

Then by the divergence theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \iiint_E 0 dx dy dz = \boxed{0}.$$

Applications and Extensions

19. We have

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 1 + 1 + 1 = 3,$$

so that by the Divergence Theorem

$$\frac{1}{3} \iint_S \mathbf{F} \cdot \mathbf{n} dS = \frac{1}{3} \iiint_E \operatorname{div} \mathbf{F} dV = \frac{1}{3} \iiint_E 3 dx dy dz = \iiint_E dx dy dz,$$

which is an integral expressing the volume V of E .

20. Placing the solid in the first octant with one vertex at the origin, the sides of the parallelepiped are given by $x = 0$, $y = 0$, $z = 0$, $x = a$, $y = b$, $z = c$. Then

$$\frac{1}{3} \iint_S \mathbf{F} \cdot \mathbf{n} dS$$

is composed of six separate integrals, one along each face:

Face	$\mathbf{n}$	$\mathbf{F}$	$\mathbf{F} \cdot \mathbf{n}$
$S_1 : x = 0$	$-\mathbf{i}$	$y\mathbf{j} + z\mathbf{k}$	0
$S_2 : y = 0$	$-\mathbf{j}$	$x\mathbf{i} + z\mathbf{k}$	0
$S_3 : z = 0$	$-\mathbf{k}$	$x\mathbf{i} + y\mathbf{j}$	0
$S_4 : x = a$	$\mathbf{i}$	$a\mathbf{i} + y\mathbf{j} + z\mathbf{k}$	a
$S_5 : y = b$	$\mathbf{j}$	$x\mathbf{i} + b\mathbf{j} + z\mathbf{k}$	b
$S_6 : z = c$	$\mathbf{k}$	$x\mathbf{i} + y\mathbf{j} + c\mathbf{k}$	c

The integrals over S_1 , S_2 , and S_3 are clearly zero. For S_4 , the integral is over $0 \leq y \leq b$ and $0 \leq z \leq c$; for S_5 , it is over $0 \leq x \leq a$ and $0 \leq z \leq c$; and for S_6 , it is over $0 \leq x \leq a$ and $0 \leq y \leq b$. Therefore we get

$$\begin{aligned} V &= \frac{1}{3} \iint_S \mathbf{F} \cdot \mathbf{n} dS \\ &= \frac{1}{3} \sum_{i=1}^6 \iint_{S_i} \mathbf{F} \cdot \mathbf{n} dS \\ &= \frac{1}{3} \left(\int_0^b \int_0^c a dz dy + \int_0^a \int_0^c b dz dx + \int_0^a \int_0^b c dy dx \right) \\ &= \frac{1}{3} \left(\int_0^b [az]_0^c dy + \int_0^a [bz]_0^c dx + \int_0^a [cy]_0^b dx \right) \\ &= \frac{1}{3} \left(\int_0^b ac dy + \int_0^a bc dx + \int_0^a bc dx \right) \\ &= \frac{1}{3} \left([acy]_0^b + [bcx]_0^a + [bcx]_0^a \right) \\ &= \frac{1}{3} (abc + abc + abc) = \boxed{abc}. \end{aligned}$$

21. Assume the cone is oriented as shown in the figure in the text. To determine the volume of the cone using the required formula, we must integrate both over the lateral surface of the cone and over its top. Do this first for the lateral surface; start by determining parametric equations for this surface using cylindrical coordinates. A cross-section of the cone in the yz -plane looks like this:

Using similar triangles, we see that $\frac{h}{R} = \frac{z}{r}$, so that $z = \frac{h}{R}r$. Then a cylindrical parametrization for the cone is

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + \frac{h}{R}r \mathbf{k}, \quad 0 \leq r \leq R, \quad 0 \leq \theta \leq 2\pi.$$

We get

$$\begin{aligned} \mathbf{r}_r &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + \frac{h}{R} \mathbf{k}, & \mathbf{r}_\theta &= -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j} \\ \mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & \frac{h}{R} \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = -\frac{h}{R}r \cos \theta \mathbf{i} - \frac{h}{R}r \sin \theta \mathbf{j} + r \mathbf{k} \\ \|\mathbf{r}_r \times \mathbf{r}_\theta\| &= \sqrt{\frac{h^2}{R^2}r^2 \cos^2 \theta + \frac{h^2}{R^2}r^2 \sin^2 \theta + r^2} = r\sqrt{1 + \frac{h^2}{R^2}} = \frac{r}{R}\sqrt{R^2 + h^2}. \end{aligned}$$

With $\mathbf{F} = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + \frac{h}{R}r \mathbf{k}$, we get

$$\begin{aligned} \frac{1}{3} \iint_S \mathbf{F} \cdot \mathbf{n} dS &= \frac{1}{3} \int_0^R \int_0^{2\pi} \left(r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + \frac{h}{R}r \mathbf{k} \right) \cdot \left(-\frac{h}{R}r \cos \theta \mathbf{i} - \frac{h}{R}r \sin \theta \mathbf{j} + r \mathbf{k} \right) \\ &\quad \cdot \frac{1}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| d\theta dr \\ &= \frac{1}{3} \int_0^R \int_0^{2\pi} \left(r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + \frac{h}{R}r \mathbf{k} \right) \cdot \left(-\frac{h}{R}r \cos \theta \mathbf{i} - \frac{h}{R}r \sin \theta \mathbf{j} + r \mathbf{k} \right) d\theta dr \\ &= \frac{1}{3} \int_0^R \int_0^{2\pi} \left(-\frac{h}{R}r^2 \cos^2 \theta - \frac{h}{R}r^2 \sin^2 \theta + \frac{h}{R}r^2 \right) d\theta dr \\ &= \frac{1}{3} \int_0^R \int_0^{2\pi} 0 d\theta dr = 0. \end{aligned}$$

So this piece of the surface integral is zero. For the top of the cone, note that it is a disk of radius R , parametrized by

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + h \mathbf{k}, \quad 0 \leq r \leq R, \quad 0 \leq \theta \leq 2\pi.$$

We get

$$\begin{aligned}\mathbf{r}_r &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, & \mathbf{r}_\theta &= -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j} \\ \mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 0 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = r \mathbf{k} \\ \|\mathbf{r}_r \times \mathbf{r}_\theta\| &= \|r \mathbf{k}\| = r.\end{aligned}$$

With $\mathbf{F} = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + h \mathbf{k}$, we get

$$\begin{aligned}\frac{1}{3} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \frac{1}{3} \int_0^R \int_0^{2\pi} (r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + h \mathbf{k}) \cdot r \mathbf{k} \cdot \frac{1}{r} \cdot r \, d\theta \, dr \\ &= \frac{1}{3} \int_0^R \int_0^{2\pi} r h \, d\theta \, dr \\ &= \frac{2\pi}{3} \int_0^R r h \, dr \\ &= \frac{2\pi}{3} \left[\frac{1}{2} r^2 h \right]_0^R = \frac{1}{3} \pi R^2 h.\end{aligned}$$

Since the first integral was zero, the volume of the cone is just the second integral, or $\boxed{\frac{1}{3} \pi R^2 h}$.

22. Center the sphere at the origin, and parametrize it using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = R \cos \theta \sin \phi \mathbf{i} + R \sin \theta \sin \phi \mathbf{j} + R \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

Then

$$\begin{aligned}\mathbf{r}_\theta &= -R \sin \theta \sin \phi \mathbf{i} + R \cos \theta \sin \phi \mathbf{j}, & \mathbf{r}_\phi &= R \cos \theta \cos \phi \mathbf{i} + R \sin \theta \cos \phi \mathbf{j} - R \sin \phi \mathbf{k} \\ \mathbf{r}_\theta \times \mathbf{r}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -R \sin \theta \sin \phi & R \cos \theta \sin \phi & 0 \\ R \cos \theta \cos \phi & R \sin \theta \cos \phi & -R \sin \phi \end{vmatrix} \\ &= -R^2 \cos \theta \sin^2 \phi \mathbf{i} - R^2 \sin \theta \sin^2 \phi \mathbf{j} - R^2 \sin \phi \cos \phi \mathbf{k} \\ \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| &= \sqrt{R^4 \cos^2 \theta \sin^4 \phi + R^4 \sin^2 \theta \sin^4 \phi + R^4 \cos^4 \theta \sin^2 \phi \cos^2 \phi} \\ &= R^2 \sqrt{\sin^4 \phi + \sin^2 \phi \cos^2 \phi} = R^2 \sin \phi.\end{aligned}$$

Then with

$$\mathbf{F} = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = R \cos \theta \sin \phi \mathbf{i} + R \sin \theta \sin \phi \mathbf{j} + R \cos \phi \mathbf{k},$$

we get

$$\begin{aligned}
\frac{1}{3} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \frac{1}{3} \int_0^{2\pi} \int_0^\pi (R \cos \theta \sin \phi \mathbf{i} + R \sin \theta \sin \phi \mathbf{j} + R \cos \phi \mathbf{k}) \cdot \\
&\quad (-R^2 \cos \theta \sin^2 \phi \mathbf{i} - R^2 \sin \theta \sin^2 \phi \mathbf{j} - R^2 \sin \phi \cos \phi \mathbf{k}) \\
&\quad \cdot \frac{1}{\|\mathbf{r}_\theta \times \mathbf{r}_\phi\|} \cdot \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| \, d\phi \, d\theta \\
&= \frac{1}{3} \int_0^{2\pi} \int_0^\pi (R \cos \theta \sin \phi \mathbf{i} + R \sin \theta \sin \phi \mathbf{j} + R \cos \phi \mathbf{k}) \cdot \\
&\quad (-R^2 \cos \theta \sin^2 \phi \mathbf{i} - R^2 \sin \theta \sin^2 \phi \mathbf{j} - R^2 \sin \phi \cos \phi \mathbf{k}) \, d\phi \, d\theta \\
&= \frac{1}{3} \int_0^{2\pi} \int_0^\pi (-R^3 \cos^2 \theta \sin^3 \phi - R^3 \sin^2 \theta \sin^3 \phi - R^3 \sin \phi \cos^2 \phi) \, d\phi \, d\theta \\
&= -\frac{1}{3} R^3 \int_0^{2\pi} \int_0^\pi (\sin^3 \phi + \sin \phi \cos^2 \phi) \, d\phi \, d\theta \\
&= -\frac{1}{3} R^3 \int_0^{2\pi} \int_0^\pi \sin \phi (\sin^2 \phi + \cos^2 \phi) \, d\phi \, d\theta \\
&= -\frac{1}{3} R^3 \int_0^{2\pi} \int_0^\pi \sin \phi \, d\phi \, d\theta \\
&= -\frac{1}{3} R^3 \int_0^{2\pi} [-\cos \phi]_0^\pi \, d\theta \\
&= \frac{1}{3} R^3 \int_0^{2\pi} 2 \, d\theta = \boxed{\frac{4}{3} \pi R^3}.
\end{aligned}$$

23. Parametrize the surface of the sphere, which has radius 10, using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = 10 \cos \theta \sin \phi \mathbf{i} + 10 \sin \theta \sin \phi \mathbf{j} + 10 \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

Then

$$\begin{aligned}
\mathbf{r}_\theta &= -10 \sin \theta \sin \phi \mathbf{i} + 10 \cos \theta \sin \phi \mathbf{j} & \mathbf{r}_\phi &= 10 \cos \theta \cos \phi \mathbf{i} + 10 \sin \theta \cos \phi \mathbf{j} - 10 \sin \phi \mathbf{k} \\
\mathbf{r}_\theta \times \mathbf{r}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -10 \sin \theta \sin \phi & 10 \cos \theta \sin \phi & 0 \\ 10 \cos \theta \cos \phi & 10 \sin \theta \cos \phi & -10 \sin \phi \end{vmatrix} \\
&= -100 \cos \theta \sin^2 \phi \mathbf{i} - 100 \sin \theta \sin^2 \phi \mathbf{j} - 100 \sin \phi \cos \phi \mathbf{k} \\
\|\mathbf{r}_\theta \times \mathbf{r}_\phi\| &= \sqrt{10000 \cos^2 \theta \sin^4 \phi + 10000 \sin^2 \theta \sin^4 \phi + 10000 \cos^4 \theta \sin^2 \phi \cos^2 \phi} \\
&= 100 \sqrt{\sin^4 \phi + \sin^2 \phi \cos^2 \phi} = 100 \sin \phi.
\end{aligned}$$

Then with

$$\mathbf{F} = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = 10 \cos \theta \sin \phi \mathbf{i} + 10 \sin \theta \sin \phi \mathbf{j} + 10 \cos \phi \mathbf{k},$$

we get

$$\begin{aligned}
\iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^{2\pi} \int_0^\pi (10 \cos \theta \sin \phi \mathbf{i} + 10 \sin \theta \sin \phi \mathbf{j} + 10 \cos \phi \mathbf{k}) \cdot \\
&\quad (-100 \cos \theta \sin^2 \phi \mathbf{i} - 100 \sin \theta \sin^2 \phi \mathbf{j} - 100 \sin \phi \cos \phi \mathbf{k}) \\
&\quad \cdot \frac{1}{\|\mathbf{r}_\theta \times \mathbf{r}_\phi\|} \cdot \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| \, d\phi \, d\theta \\
&= \int_0^{2\pi} \int_0^\pi (10 \cos \theta \sin \phi \mathbf{i} + 10 \sin \theta \sin \phi \mathbf{j} + 10 \cos \phi \mathbf{k}) \cdot \\
&\quad (-100 \cos \theta \sin^2 \phi \mathbf{i} - 100 \sin \theta \sin^2 \phi \mathbf{j} - 100 \sin \phi \cos \phi \mathbf{k}) \, d\phi \, d\theta \\
&= \int_0^{2\pi} \int_0^\pi (-1000 \cos^2 \theta \sin^3 \phi - 1000 \sin^2 \theta \sin^3 \phi - 1000 \sin \phi \cos^2 \phi) \, d\phi \, d\theta \\
&= -1000 \int_0^{2\pi} \int_0^\pi (\sin^3 \phi + \sin \phi \cos^2 \phi) \, d\phi \, d\theta \\
&= -1000 \int_0^{2\pi} \int_0^\pi \sin \phi (\sin^2 \phi + \cos^2 \phi) \, d\phi \, d\theta \\
&= -1000 \int_0^{2\pi} \int_0^\pi \sin \phi \, d\phi \, d\theta \\
&= -1000 \int_0^{2\pi} [-\cos \phi]_0^\pi \, d\theta \\
&= 1000 \int_0^{2\pi} 2 \, d\theta = 4000\pi.
\end{aligned}$$

For the second form, since

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 3,$$

we parametrize again using spherical coordinates; the solid sphere is

$$\mathbf{r}(r, \theta, \phi) = r \cos \theta \sin \phi \mathbf{i} + r \sin \theta \sin \phi \mathbf{j} + r \cos \phi \mathbf{k}, \quad 0 \leq r \leq 10, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

Then the solid integral is

$$\begin{aligned}
\iiint_E \operatorname{div} \mathbf{F} \, dV &= \int_0^{10} \int_0^{2\pi} \int_0^\pi 3r^2 \sin \phi \, d\phi \, d\theta \, dr \\
&= \int_0^{10} \int_0^{2\pi} [-3r^2 \cos \phi]_0^\pi \, d\theta \, dr \\
&= \int_0^{10} \int_0^{2\pi} 6r^2 \, d\theta \, dr \\
&= \int_0^{10} 12\pi r^2 \, dr \\
&= [4\pi r^3]_0^{10} = \boxed{4000\pi}.
\end{aligned}$$

The two results are the same.

24. The surface of the cylinder consists of three pieces: the top, S_1 , the lateral curved surface, S_2 , and the bottom, S_3 . We parametrize all three surfaces using cylindrical coordinates:

$$\begin{aligned}
S_1 : \quad \mathbf{r}(r, \theta) &= r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + 2 \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi \\
S_2 : \quad \mathbf{s}(\theta, z) &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq 2 \\
S_3 : \quad \mathbf{t}(r, \theta) &= r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.
\end{aligned}$$

Then

$$\begin{aligned}
\mathbf{r}_r &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, & \mathbf{r}_\theta &= -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j} \\
\mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 0 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = r \mathbf{k} \\
\mathbf{s}_\theta &= -\sin \theta \mathbf{i} + \cos \theta \mathbf{j}, & \mathbf{s}_z &= \mathbf{k} \\
\mathbf{s}_\theta \times \mathbf{s}_z &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} \\
\mathbf{t}_r &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, & \mathbf{t}_\theta &= -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j} \\
\mathbf{t}_r \times \mathbf{t}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 0 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = r \mathbf{k}.
\end{aligned}$$

We need all of the normals we use to be outward-pointing. $r \mathbf{k}$ points upwards, which is outwards, along the top, and $\cos \theta \mathbf{i} + \sin \theta \mathbf{j}$ points outwards along the lateral surface. However, $r \mathbf{k}$ points upwards, which is inwards, along the bottom, so we must use instead $-r \mathbf{k}$ along the bottom. Therefore

$$\begin{aligned}
\iint_S \mathbf{F} \cdot \mathbf{n} dS &= \iint_{S_1} \mathbf{F} \cdot \mathbf{n} dS + \iint_{S_2} \mathbf{F} \cdot \mathbf{n} dS + \iint_{S_3} \mathbf{F} \cdot \mathbf{n} dS \\
&= \int_0^1 \int_0^{2\pi} (r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + 2 \mathbf{k}) \cdot r \mathbf{k} \cdot \frac{1}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| d\theta dr \\
&\quad + \int_0^1 \int_0^{2\pi} (\cos \theta \mathbf{i} + \sin \theta \mathbf{j} + z \mathbf{k}) \cdot (\cos \theta \mathbf{i} + \sin \theta \mathbf{j}) \cdot \frac{1}{\|\mathbf{s}_\theta \times \mathbf{s}_z\|} \cdot \|\mathbf{s}_\theta \times \mathbf{s}_z\| dz d\theta \\
&\quad + \int_0^1 \int_0^{2\pi} (r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j}) \cdot (-r \mathbf{k}) \cdot \frac{1}{\|\mathbf{t}_r \times \mathbf{t}_\theta\|} \cdot \|\mathbf{t}_r \times \mathbf{t}_\theta\| d\theta dr \\
&= \int_0^1 \int_0^{2\pi} 2r d\theta dr + \int_0^1 \int_0^{2\pi} (\cos^2 \theta + \sin^2 \theta) dz d\theta + \int_0^1 \int_0^{2\pi} 0 d\theta dr \\
&= \int_0^1 4\pi r dr + \int_0^1 \int_0^{2\pi} 1 dz d\theta \\
&= [2\pi r^2]_0^1 + 4\pi = 6\pi.
\end{aligned}$$

For the second form, since

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 3,$$

we parametrize again using cylindrical coordinates; the solid cylinder is

$$\mathbf{r}(r, \theta, \phi) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq 2.$$

Then the solid integral is

$$\begin{aligned}
\iiint_E \operatorname{div} \mathbf{F} dV &= \int_0^1 \int_0^{2\pi} \int_0^2 3r dz d\theta dr \\
&= \int_0^1 \int_0^{2\pi} [3rz]_0^2 d\theta dr \\
&= \int_0^1 \int_0^{2\pi} 6r d\theta dr \\
&= \int_0^1 12\pi r dr = [6\pi r^2]_0^1 = \boxed{6\pi}.
\end{aligned}$$

The two results are the same.

25. If $\mathbf{F}$ is constant, then $\operatorname{div} \mathbf{F} = 0$ since all three components of $\mathbf{F}$ are zero. Since E satisfies the conditions of the Divergence Theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \iiint_E 0 dV = 0.$$

26. Since

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \frac{\partial}{\partial x}(3x) + \frac{\partial}{\partial y}(4y) + \frac{\partial}{\partial z}(7z + 2x) = 3 + 4 + 7 = 14 \\ \operatorname{div} \mathbf{G} &= \frac{\partial}{\partial x}(2x) + \frac{\partial}{\partial y}(3y) + \frac{\partial}{\partial z}(9z + 6y) = 2 + 3 + 9 = 14, \end{aligned}$$

the two vector fields have the same divergence. Since E satisfies the assumptions of the Divergence Theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \iiint_E \operatorname{div} \mathbf{G} dV = \iint_S \mathbf{G} \cdot \mathbf{n} dS.$$

27. (a) The velocity is a vector field $\mathbf{F}$; saying that the velocity is constant is the same as saying that the vector field is constant. Let the closed surface be S and the solid it bounds be E . Then by Problem 25 (as long as we assume that E satisfies the conditions of the Divergence Theorem) we know that the flux, which is $\iint_S \mathbf{F} \cdot \mathbf{n} dS$, is zero.

(b) Answers will vary.

- 28.

$$\mathbf{F} = \frac{1}{\rho}(x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) = \frac{x}{\sqrt{x^2 + y^2 + z^2}}\mathbf{i} + \frac{y}{\sqrt{x^2 + y^2 + z^2}}\mathbf{j} + \frac{z}{\sqrt{x^2 + y^2 + z^2}}\mathbf{k}.$$

Then

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \frac{\partial}{\partial x} \left(\frac{x}{\sqrt{x^2 + y^2 + z^2}} \right) + \frac{\partial}{\partial y} \left(\frac{y}{\sqrt{x^2 + y^2 + z^2}} \right) + \frac{\partial}{\partial z} \left(\frac{z}{\sqrt{x^2 + y^2 + z^2}} \right) \\ &= \frac{(x^2 + y^2 + z^2)^{1/2} \cdot 1 - x \cdot \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2x}{x^2 + y^2 + z^2} \\ &\quad + \frac{(x^2 + y^2 + z^2)^{1/2} \cdot 1 - y \cdot \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2y}{x^2 + y^2 + z^2} \\ &\quad + \frac{(x^2 + y^2 + z^2)^{1/2} \cdot 1 - z \cdot \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2z}{x^2 + y^2 + z^2} \\ &= \frac{3(x^2 + y^2 + z^2)^{1/2} - (x^2 + y^2 + z^2)(x^2 + y^2 + z^2)^{-1/2}}{x^2 + y^2 + z^2} \\ &= \frac{3(x^2 + y^2 + z^2)^{1/2} - (x^2 + y^2 + z^2)^{1/2}}{x^2 + y^2 + z^2} \\ &= \frac{2}{\sqrt{x^2 + y^2 + z^2}} = \frac{2}{\rho}. \end{aligned}$$

29. (a) Let $\mathbf{F}$ be as in Problem 28. Then

$$\iiint_E \frac{dV}{\sqrt{x^2 + y^2 + z^2}} = \frac{1}{2} \iiint_E \frac{2}{\rho} dV = \frac{1}{2} \iiint_E \operatorname{div} \mathbf{F} dV = \frac{1}{2} \iint_S \mathbf{F} \cdot \mathbf{n} dS,$$

where S is the surface of the unit sphere. Parametrizing the unit sphere using spherical coordinates gives

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi.$$

Then

$$\begin{aligned}
 \mathbf{r}_\theta &= -\sin \theta \sin \phi \mathbf{i} + \cos \theta \sin \phi \mathbf{j} & \mathbf{r}_\phi &= \cos \theta \cos \phi \mathbf{i} + \sin \theta \cos \phi \mathbf{j} - \sin \phi \mathbf{k} \\
 \mathbf{r}_\theta \times \mathbf{r}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \end{vmatrix} = -\cos \theta \sin^2 \phi \mathbf{i} - \sin \theta \sin^2 \phi \mathbf{j} - \sin \phi \cos \phi \mathbf{k} \\
 \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| &= \sqrt{\cos^2 \theta \sin^4 \phi + \sin^2 \theta \sin^4 \phi + \cos^4 \theta \sin^2 \phi \cos^2 \phi} \\
 &= \sqrt{\sin^4 \phi + \sin^2 \phi \cos^2 \phi} = \sin \phi.
 \end{aligned}$$

Note that $\mathbf{r}_\theta \times \mathbf{r}_\phi$ is the inward-pointing normal, so we will use its negative, which will be the outward-pointing normal. Then with

$$\mathbf{F} = \frac{1}{\sqrt{x^2 + y^2 + z^2}} (x \mathbf{i} + y \mathbf{j} + z \mathbf{k}) = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k},$$

the surface integral is

$$\begin{aligned}
 \frac{1}{2} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \frac{1}{2} \int_0^{2\pi} \int_0^\pi (\cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}) \\
 &\quad \cdot (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}) \cdot \frac{1}{\|\mathbf{r}_\theta \times \mathbf{r}_\phi\|} \\
 &\quad \cdot \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| \, d\phi \, d\theta \\
 &= \frac{1}{2} \int_0^{2\pi} \int_0^\pi (\cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}) \\
 &\quad \cdot (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}) \, d\phi \, d\theta \\
 &= \frac{1}{2} \int_0^{2\pi} \int_0^\pi (\cos^2 \theta \sin^3 \phi + \sin^2 \theta \sin^3 \phi + \sin \phi \cos^2 \phi) \, d\phi \, d\theta \\
 &= \frac{1}{2} \int_0^{2\pi} \int_0^\pi (\sin^3 \phi + \sin \phi \cos^2 \phi) \, d\phi \, d\theta \\
 &= \frac{1}{2} \int_0^{2\pi} \int_0^\pi \sin \phi \, d\phi \, d\theta \\
 &= \frac{1}{2} \int_0^{2\pi} [-\cos \phi]_0^\pi \, d\theta \\
 &= \frac{1}{2} \int_0^{2\pi} 2 \, d\theta = \boxed{2\pi}.
 \end{aligned}$$

(b) Evaluate the integral using spherical coordinates; then $\sqrt{x^2 + y^2 + z^2} = \sqrt{r^2} = r$, so we get

$$\begin{aligned}
 \iiint_E \frac{dV}{\sqrt{x^2 + y^2 + z^2}} &= \int_0^1 \int_0^{2\pi} \int_0^\pi \frac{r^2 \sin \phi}{r} \, d\phi \, d\theta \, dr \\
 &= \int_0^1 \int_0^{2\pi} \int_0^\pi r \sin \phi \, d\phi \, d\theta \, dr \\
 &= \int_0^1 \int_0^{2\pi} [-r \cos \phi]_0^\pi \, d\theta \, dr \\
 &= \int_0^1 \int_0^{2\pi} 2r \, d\theta \, dr \\
 &= \int_0^1 4\pi r \, dr \\
 &= [2\pi r^2]_0^1 = 2\pi.
 \end{aligned}$$

30. We have

$$\nabla f = f_x \mathbf{i} + f_y \mathbf{j} + f_z \mathbf{k},$$

so that

$$\operatorname{div} \nabla f = \frac{\partial}{\partial x}(f_x) + \frac{\partial}{\partial y}(f_y) + \frac{\partial}{\partial z}(f_z) = f_{xx} + f_{yy} + f_{zz} = 0$$

if f satisfies the Laplace equation. Now, ∇f is a vector field, and by the hypotheses, invoking the Divergence Theorem gives

$$\iint_S \nabla f \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \nabla f \, dV = \iiint_E 0 \, dV = 0.$$

Challenge Problems

31. Rearranging the equation gives

$$x^2 + y^2 + z^2 - 2qz = 0, \text{ or } x^2 + y^2 + (z - q)^2 = q^2,$$

which is a sphere centered at $(0, 0, q)$ of radius q . Now,

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(z^2) = 2x + 2y + 2z,$$

so that using the Divergence Theorem,

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E (2x + 2y + 2z) \, dV.$$

Evaluate this integral using spherical coordinates:

$$\begin{aligned} \iiint_E (2x + 2y + 2z) \, dV &= \int_0^\pi \int_0^{2\pi} \int_0^q (2x + 2y + 2z) \, dV \\ &= \int_0^\pi \int_0^{2\pi} \int_0^q (2r \cos \theta \sin \phi + 2r \sin \theta \sin \phi + 2q + 2r \cos \phi) \cdot r^2 \sin \phi \, dr \, d\theta \, d\phi \\ &= \int_0^\pi \int_0^{2\pi} \int_0^q (2r^3 \cos \theta \sin^2 \phi + 2r^3 \sin \theta \sin^2 \phi + 2qr^2 \sin \phi + 2r^3 \cos \phi \sin \phi) \, dr \, d\theta \, d\phi \\ &= \int_0^\pi \int_0^{2\pi} \left[\frac{1}{2} r^4 \cos \theta \sin^2 \phi + \frac{1}{2} r^4 \sin \theta \sin^2 \phi + \frac{2}{3} q r^3 \sin \phi + \frac{1}{2} r^4 \cos \phi \sin \phi \right]_0^q \, d\theta \, d\phi \\ &= \int_0^\pi \int_0^{2\pi} \left(\frac{q^4}{2} \sin^2 \phi (\cos \theta + \sin \theta) + \frac{2}{3} q^4 \sin \phi + \frac{1}{2} q^4 \cos \phi \sin \phi \right) \, d\theta \, d\phi \\ &= q^4 \int_0^\pi \left[\frac{1}{2} \sin^2 \phi (\sin \theta - \cos \theta) + \frac{2}{3} \theta \sin \phi + \frac{1}{2} \theta \cos \phi \sin \phi \right]_0^{2\pi} \, d\phi \\ &= q^4 \int_0^\pi \left(\frac{4\pi}{3} \sin \phi + \pi \cos \phi \sin \phi \right) \, d\phi \\ &= q^4 \left[-\frac{4\pi}{3} \cos \phi + \frac{\pi}{2} \sin^2 \phi \right]_0^\pi \\ &= \boxed{\frac{8\pi q^4}{3}}. \end{aligned}$$

32. The interior of the cube is defined by $0 \leq x \leq q$, $0 \leq y \leq q$, $0 \leq z \leq q$, and

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(z^2) = 2x + 2y + 2z.$$

So by the Divergence Theorem,

$$\begin{aligned}
 \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \iiint_E \operatorname{div} \mathbf{F} \, dV \\
 &= \int_0^q \int_0^q \int_0^q (2x + 2y + 2z) \, dx \, dy \, dz \\
 &= \int_0^q \int_0^q [x^2 + 2xy + 2xz]_0^q \, dy \, dz \\
 &= \int_0^q \int_0^q (2qy + 2qz + q^2) \, dy \, dz \\
 &= \int_0^q [qy^2 + 2qyz + q^2y]_0^q \, dz \\
 &= \int_0^q (q^3 + 2q^2z + q^3) \, dz \\
 &= [2q^3z + q^2z^2]_0^q \\
 &= 2q^4 + q^4 = \boxed{3q^4}.
 \end{aligned}$$

33. With

$$\mathbf{F} = f(\nabla g) = fg_x \mathbf{i} + fg_y \mathbf{j} + fg_z \mathbf{k},$$

we have

$$\begin{aligned}
 \operatorname{div} \mathbf{F} &= \frac{\partial}{\partial x}(fg_x) + \frac{\partial}{\partial y}(fg_y) + \frac{\partial}{\partial z}(fg_z) \\
 &= f_x g_x + f g_{xx} + f_y g_y + f g_{yy} + f_z g_z + f g_{zz} \\
 &= \langle f_x, f_y, f_z \rangle \cdot \langle g_x, g_y, g_z \rangle + f(g_{xx} + g_{yy} + g_{zz}) \\
 &= f(\nabla^2 g) + \nabla f \cdot \nabla g.
 \end{aligned}$$

Then since E satisfies the assumptions of the Divergence Theorem, we have

$$\iint_S f(\nabla g) \cdot \mathbf{n} \, dS = \iiint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \mathbf{F} \, dV = \iiint_E [f(\nabla^2 g) + \nabla f \cdot \nabla g] \, dV.$$

15.9: Stokes' Theorem

Concepts and Vocabulary

1. False. $\operatorname{curl} \mathbf{F}$ is a vector; see the introduction to this section.
2. We have

$$\begin{aligned}
 \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ e^{-x^2/2} - yz & e^{-y^2/2} + xz + 2x & e^{-z^2/2} + 5 \end{vmatrix} \\
 &= \left(\frac{\partial}{\partial y}(e^{-z^2/2} + 5) - \frac{\partial}{\partial z}(e^{-y^2/2} + xz + 2x) \right) \mathbf{i} \\
 &\quad + \left(\frac{\partial}{\partial z}(e^{-x^2/2} - yz) - \frac{\partial}{\partial x}(e^{-z^2/2} + 5) \right) \mathbf{j} \\
 &\quad + \left(\frac{\partial}{\partial x}(e^{-y^2/2} + xz + 2x) - \frac{\partial}{\partial y}(e^{-x^2/2} - yz) \right) \mathbf{k} \\
 &= (0 - x) \mathbf{i} + (-y - 0) \mathbf{j} + ((z + 2) - (-z)) \mathbf{k} \\
 &= -x \mathbf{i} - y \mathbf{j} + (2z + 2) \mathbf{k}.
 \end{aligned}$$

3. (c), $\mathbf{0}$, is correct. See the first theorem in Objective 4.
4. False. See the discussion in Objective 5; the component of the curl in the direction of the normal to the surface measures this circulation.
5. By the theorem on Curl and Angular Velocity in Objective 5, $\text{curl } \mathbf{F} = 2\omega$.
6. False. See the Summary in Objective 5.

Skill Building

7. We have

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x & y & 0 \end{vmatrix} = \left(\frac{\partial}{\partial y}(0) - \frac{\partial}{\partial z}(y) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(x) - \frac{\partial}{\partial x}(0) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(y) - \frac{\partial}{\partial y}(x) \right) \mathbf{k} = \boxed{\mathbf{0}}.$$

8. We have

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & x & 0 \end{vmatrix} = \left(\frac{\partial}{\partial y}(0) - \frac{\partial}{\partial z}(x) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(y) - \frac{\partial}{\partial x}(0) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(x) - \frac{\partial}{\partial y}(y) \right) \mathbf{k} = \boxed{\mathbf{0}}.$$

9. We have

$$\begin{aligned} \text{curl } \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xyz & xz & z \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(z) - \frac{\partial}{\partial z}(xz) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(xyz) - \frac{\partial}{\partial x}(z) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(xz) - \frac{\partial}{\partial y}(xyz) \right) \mathbf{k} \\ &= \boxed{-x \mathbf{i} + xy \mathbf{j} + (z - xz) \mathbf{k}}. \end{aligned}$$

10. We have

$$\begin{aligned} \text{curl } \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 4x & -y & -2z \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(-2z) - \frac{\partial}{\partial z}(-y) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(4x) - \frac{\partial}{\partial x}(-2z) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(-y) - \frac{\partial}{\partial y}(4x) \right) \mathbf{k} = \boxed{\mathbf{0}}. \end{aligned}$$

11. We have

$$\begin{aligned} \text{curl } \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 3xyz^2 & y^2 \sin z & xe^{2z} \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(xe^{2z}) - \frac{\partial}{\partial z}(y^2 \sin z) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(3xyz^2) - \frac{\partial}{\partial x}(xe^{2z}) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(y^2 \sin z) - \frac{\partial}{\partial y}(3xyz^2) \right) \mathbf{k} \\ &= \boxed{-y^2 \cos z \mathbf{i} + (6xyz - e^{2z}) \mathbf{j} - 3xz^2 \mathbf{k}}. \end{aligned}$$

12. We have

$$\begin{aligned} \text{curl } \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ yz & z^2x & yz \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(yz) - \frac{\partial}{\partial z}(z^2x) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(yz) - \frac{\partial}{\partial x}(yz) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(z^2x) - \frac{\partial}{\partial y}(yz) \right) \mathbf{k} \\ &= \boxed{(z - 2zx) \mathbf{i} + y \mathbf{j} + (z^2 - z) \mathbf{k}}. \end{aligned}$$

13. We have

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{x}{x^2+y^2+z^2} & \frac{y}{x^2+y^2+z^2} & \frac{1}{x^2+y^2+z^2} \end{vmatrix}.$$

Now,

$$\frac{\partial}{\partial y} \left(\frac{x}{x^2+y^2+z^2} \right) = \frac{\partial}{\partial y} (x(x^2+y^2+z^2)^{-1}) = -x(x^2+y^2+z^2)^{-2} \cdot 2y = -\frac{2xy}{(x^2+y^2+z^2)^2}.$$

In a similar manner, we get

$$\begin{aligned} \frac{\partial}{\partial z} \left(\frac{x}{x^2+y^2+z^2} \right) &= -\frac{2xz}{(x^2+y^2+z^2)^2} \\ \frac{\partial}{\partial x} \left(\frac{y}{x^2+y^2+z^2} \right) &= -\frac{2xy}{(x^2+y^2+z^2)^2} \\ \frac{\partial}{\partial z} \left(\frac{y}{x^2+y^2+z^2} \right) &= -\frac{2yz}{(x^2+y^2+z^2)^2}. \end{aligned}$$

For the $\mathbf{k}$ component, we have

$$\begin{aligned} \frac{\partial}{\partial x} \left(\frac{1}{x^2+y^2+z^2} \right) &= -\frac{2x}{(x^2+y^2+z^2)^2} \\ \frac{\partial}{\partial y} \left(\frac{1}{x^2+y^2+z^2} \right) &= -\frac{2y}{(x^2+y^2+z^2)^2}. \end{aligned}$$

Putting these together gives

$$\begin{aligned} \operatorname{curl} \mathbf{F} &= \left(-\frac{2y}{(x^2+y^2+z^2)^2} + \frac{2yz}{(x^2+y^2+z^2)^2} \right) \mathbf{i} \\ &\quad + \left(\frac{2x}{(x^2+y^2+z^2)^2} - \frac{2xz}{(x^2+y^2+z^2)^2} \right) \mathbf{j} \\ &\quad + \left(-\frac{2xy}{(x^2+y^2+z^2)^2} + \frac{2xy}{(x^2+y^2+z^2)^2} \right) \mathbf{k} \\ &= \boxed{\frac{2y(z-1)}{(x^2+y^2+z^2)^2} \mathbf{i} + \frac{2x(1-z)}{(x^2+y^2+z^2)^2} \mathbf{j}}. \end{aligned}$$

14. We have

$$\begin{aligned} \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ e^x & x^2y & e^z \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(e^z) - \frac{\partial}{\partial z}(x^2y) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(e^x) - \frac{\partial}{\partial x}(e^z) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(x^2y) - \frac{\partial}{\partial y}(e^x) \right) \mathbf{k} \\ &= \boxed{2xy \mathbf{k}}. \end{aligned}$$

15. We have

$$\begin{aligned} \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \cos x & \sin y & e^{xz} \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(e^{xz}) - \frac{\partial}{\partial z}(\sin y) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(\cos x) - \frac{\partial}{\partial x}(e^{xz}) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(\sin y) - \frac{\partial}{\partial y}(\cos x) \right) \mathbf{k} \\ &= \boxed{-ze^{xz} \mathbf{j}}. \end{aligned}$$

16. We have

$$\begin{aligned}
 \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \sin(xy) & \cos(xy^2) & x \end{vmatrix} \\
 &= \left(\frac{\partial}{\partial y}(x) - \frac{\partial}{\partial z}(\cos(xy^2)) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(\sin(xy)) - \frac{\partial}{\partial x}(x) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(\cos(xy^2)) - \frac{\partial}{\partial y}(\sin(xy)) \right) \mathbf{k} \\
 &= -\mathbf{j} + (-\sin(xy^2) \cdot y^2 - \cos(xy) \cdot x) \mathbf{k} \\
 &= \boxed{-\mathbf{j} - (y^2 \sin(xy^2) + x \cos(xy)) \mathbf{k}}.
 \end{aligned}$$

17. We have

$$\begin{aligned}
 \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x+y & y+z & z+x \end{vmatrix} \\
 &= \left(\frac{\partial}{\partial y}(z+x) - \frac{\partial}{\partial z}(y+z) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(x+y) - \frac{\partial}{\partial x}(z+x) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(y+z) - \frac{\partial}{\partial y}(x+y) \right) \mathbf{k} \\
 &= \boxed{-\mathbf{i} - \mathbf{j} - \mathbf{k}}.
 \end{aligned}$$

18. We have

$$\begin{aligned}
 \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y+z & z+x & z+y+x \end{vmatrix} \\
 &= \left(\frac{\partial}{\partial y}(z+y+x) - \frac{\partial}{\partial z}(z+x) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(y+z) - \frac{\partial}{\partial x}(z+y+x) \right) \mathbf{j} \\
 &\quad + \left(\frac{\partial}{\partial x}(z+x) - \frac{\partial}{\partial y}(y+z) \right) \mathbf{k} \\
 &= \boxed{\mathbf{0}}.
 \end{aligned}$$

19. The paraboloid together with its bounding curve is

The bounding curve C is the circle $x^2 + y^2 = 1$ in the xy -plane. Parametrize the curve by

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = (z-y) \mathbf{i} + (z+x) \mathbf{j} - (x+y) \mathbf{k} = -\sin \theta \mathbf{i} + \cos \theta \mathbf{j} - (\sin \theta + \cos \theta) \mathbf{k},$$

so that the line integral is

$$\begin{aligned}\oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j} - (\sin \theta + \cos \theta) \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} (\sin^2 \theta + \cos^2 \theta) d\theta = \int_0^{2\pi} 1 d\theta = 2\pi.\end{aligned}$$

For the other integral, parametrize the paraboloid using cylindrical coordinates:

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (1 - r^2) \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -2r \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = 2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}.$$

This is upward-pointing, so after normalization, it is the normal we want. Computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z - y & z + x & -(x + y) \end{vmatrix} = -2\mathbf{i} + 2\mathbf{j} + 2\mathbf{k}.$$

Then

$$\begin{aligned}\iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} dS &= \int_0^1 \int_0^{2\pi} (-2\mathbf{i} + 2\mathbf{j} + 2\mathbf{k}) \cdot \frac{1}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} (2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \\ &\quad \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| d\theta dr \\ &= \int_0^1 \int_0^{2\pi} (-4r^2 \cos \theta + 4r^2 \sin \theta + 2r) d\theta dr \\ &= \int_0^1 [-4r^2 \sin \theta - 4r^2 \cos \theta + 2r\theta]_0^{2\pi} dr \\ &= \int_0^1 4\pi r dr \\ &= [2\pi r^2]_0^1 = \boxed{2\pi}.\end{aligned}$$

The two answers agree.

20. See Problem 19 for a plot of the surface and boundary. The bounding curve C is the circle $x^2 + y^2 = 1$ in the xy -plane. Parametrize the curve by

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = y\mathbf{i} + z\mathbf{j} + x\mathbf{k} = \sin \theta \mathbf{i} + \cos \theta \mathbf{k}$$

so that the line integral is

$$\begin{aligned}\oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\sin \theta \mathbf{i} + \cos \theta \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} (-\sin^2 \theta) d\theta \\ &= \int_0^{2\pi} \left(-\frac{1}{2} + \frac{1}{2} \cos(2\theta)\right) d\theta \\ &= \left[-\frac{1}{2}\theta + \frac{1}{4} \sin(2\theta)\right]_0^{2\pi} = -\pi.\end{aligned}$$

For the other integral, parametrize the paraboloid using cylindrical coordinates:

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (1 - r^2) \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

Then the normal vector is

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -2r \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = 2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}.$$

This is upward-pointing, so after normalization, it is the normal we want. Computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & z & x \end{vmatrix} = -1 \mathbf{i} - 1 \mathbf{j} - 1 \mathbf{k}.$$

Then

$$\begin{aligned} \iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^1 \int_0^{2\pi} (-\mathbf{i} - \mathbf{j} - \mathbf{k}) \cdot \frac{1}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} (2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \\ &\quad \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, dr \\ &= \int_0^1 \int_0^{2\pi} (-2r^2 \cos \theta - 2r^2 \sin \theta - r) \, d\theta \, dr \\ &= \int_0^1 [-2r^2 \sin \theta + 2r^2 \cos \theta - r\theta]_0^{2\pi} \\ &= - \int_0^1 2\pi r \, dr \\ &= - [\pi r^2]_0^1 = \boxed{-\pi}. \end{aligned}$$

The two answers agree.

21. The hemisphere together with its bounding curve is

The bounding curve C is the circle $x^2 + y^2 = 1$ in the xy -plane. Parametrize the curve by

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = y \mathbf{i} - x \mathbf{j} = \sin \theta \mathbf{i} - \cos \theta \mathbf{j}$$

so that the line integral is

$$\begin{aligned}\oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\sin \theta \mathbf{i} - \cos \theta \mathbf{j}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} (-\sin^2 \theta - \cos^2 \theta) d\theta = -\int_0^{2\pi} 1 d\theta = -2\pi.\end{aligned}$$

For the other integral, parametrize the hemisphere using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

Then

$$\mathbf{r}_\phi \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \end{vmatrix} = \cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}.$$

This is upward-pointing in the given range of ϕ , so after normalization, it is the normal we want. Computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & -x & 0 \end{vmatrix} = -2\mathbf{k}.$$

Then

$$\begin{aligned}\iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} dS &= \int_0^{2\pi} \int_0^{\pi/2} -2\mathbf{k} \cdot \frac{1}{\|\mathbf{r}_\phi \times \mathbf{r}_\theta\|} (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}) \\ &\quad \cdot \|\mathbf{r}_\phi \times \mathbf{r}_\theta\| d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (-2 \sin \phi \cos \phi) d\phi d\theta \\ &= \int_0^{2\pi} [-\sin^2 \phi]_0^{\pi/2} d\theta \\ &= \int_0^{2\pi} (-1) d\theta = \boxed{-2\pi}.\end{aligned}$$

The two answers agree.

22. See Problem 21 for a plot of the surface and boundary. The bounding curve C is the circle $x^2 + y^2 = 1$ in the xy -plane. Parametrize the curve by

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = z\mathbf{i} + x\mathbf{j} + y\mathbf{k} = \cos \theta \mathbf{j} + \sin \theta \mathbf{k}$$

so that the line integral is

$$\begin{aligned}\oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\cos \theta \mathbf{j} + \sin \theta \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} \cos^2 \theta d\theta \\ &= \int_0^{2\pi} \left(\frac{1}{2} + \frac{1}{2} \cos(2\theta) \right) d\theta \\ &= \left[\frac{1}{2} \theta + \frac{1}{4} \sin(2\theta) \right]_0^{2\pi} = \pi.\end{aligned}$$

For the other integral, parametrize the hemisphere using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

Then

$$\mathbf{r}_\phi \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \end{vmatrix} = \cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}.$$

This is upward-pointing in the given range of ϕ , so after normalization, it is the normal we want. Computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z & x & y \end{vmatrix} = \mathbf{i} + \mathbf{j} + \mathbf{k}.$$

Then

$$\begin{aligned} \iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^{2\pi} \int_0^{\pi/2} (\mathbf{i} + \mathbf{j} + \mathbf{k}) \cdot \frac{1}{\|\mathbf{r}_\phi \times \mathbf{r}_\theta\|} (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}) \\ &\quad \cdot \|\mathbf{r}_\phi \times \mathbf{r}_\theta\| \, d\phi \, d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (\cos \theta \sin^2 \phi + \sin \theta \sin^2 \phi + \sin \phi \cos \phi) \, d\phi \, d\theta \\ &= \int_0^{\pi/2} \int_0^{2\pi} (\cos \theta \sin^2 \phi + \sin \theta \sin^2 \phi + \sin \phi \cos \phi) \, d\theta \, d\phi \\ &= \int_0^{\pi/2} [\sin \theta \sin^2 \phi - \cos \theta \sin^2 \phi + \theta \sin \phi \cos \phi]_0^{2\pi} \, d\phi \\ &= \int_0^{\pi/2} 2\pi \sin \phi \cos \phi \, d\phi \\ &= [\pi \sin^2 \phi]_0^{\pi/2} = \boxed{\pi}. \end{aligned}$$

The two answers agree.

23. See Problem 19 for a plot of the surface and boundary. The bounding curve C is the circle $x^2 + y^2 = 1$ in the xy -plane. Parametrize the curve by

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = y^2 \mathbf{i} + x \mathbf{j} - xz \mathbf{k} = \sin^2 \theta \mathbf{i} + \cos \theta \mathbf{j}$$

so that the line integral is

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\sin^2 \theta \mathbf{i} + \cos \theta \mathbf{j}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) \, d\theta \\ &= \int_0^{2\pi} (-\sin^3 \theta + \cos^2 \theta) \, d\theta \\ &= \int_0^{2\pi} \left(-\sin \theta (1 - \cos^2 \theta) + \frac{1}{2} + \frac{1}{2} \cos(2\theta) \right) \, d\theta \\ &= \left[\cos \theta - \frac{1}{3} \cos^3 \theta + \frac{1}{2} \theta + \frac{1}{4} \sin(2\theta) \right]_0^{2\pi} \\ &= \pi. \end{aligned}$$

For the other integral, parametrize the paraboloid using cylindrical coordinates:

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (1 - r^2) \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

Then the normal vector is

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -2r \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = 2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}.$$

This is upward-pointing, so after normalization, it is the normal we want. Computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y^2 & x & -xz \end{vmatrix} = z \mathbf{j} + (1 - 2y) \mathbf{k} = (1 - r^2) \mathbf{j} + (1 - 2r \sin \theta) \mathbf{k}.$$

Then

$$\begin{aligned} \iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^1 \int_0^{2\pi} ((1 - r^2) \mathbf{j} + (1 - 2r \sin \theta) \mathbf{k}) \cdot \frac{1}{\|\mathbf{r}_r \times \mathbf{r}_\theta\|} (2r^2 \cos \theta \mathbf{i} + 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \\ &\quad \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| \, d\theta \, dr \\ &= \int_0^1 \int_0^{2\pi} ((1 - r^2) 2r^2 \sin \theta + (1 - 2r \sin \theta) r) \, d\theta \, dr \\ &= \int_0^1 \int_0^{2\pi} 2r^2 \sin \theta - 2r^4 \sin \theta + r - 2r^2 \sin \theta \, d\theta \, dr \\ &= \int_0^1 [-2r^2 \cos \theta + 2r^4 \cos \theta + r\theta + 2r^2 \cos \theta]_0^{2\pi} \, dr \\ &= \int_0^1 2\pi r \, dr \\ &= [\pi r^2]_0^1 = \boxed{\pi}. \end{aligned}$$

The two answers agree.

24. The surface together with its bounding curve is

The bounding curve C is a circle; since $z = 5$, the circle is $5 = 1 + x^2 + y^2$, so it is a circle of radius 2. Parametrize the curve by

$$\mathbf{r}(\theta) = 2 \cos \theta \mathbf{i} + 2 \sin \theta \mathbf{j} + 5 \mathbf{k}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = 4x \mathbf{i} - y \mathbf{j} + 2z \mathbf{k} = 8 \cos \theta \mathbf{i} - 2 \sin \theta \mathbf{j} + 10 \mathbf{k}$$

so that the line integral is

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (8 \cos \theta \mathbf{i} - 2 \sin \theta \mathbf{j} + 10 \mathbf{k}) \cdot (-2 \sin \theta \mathbf{i} + 2 \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} (-20 \sin \theta \cos \theta) d\theta = [-10 \sin^2 \theta]_0^{2\pi} = 0. \end{aligned}$$

For the other integral, computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 4x & -y & 2z \end{vmatrix} = \mathbf{0}.$$

Therefore

$$\iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} dS = \iint_S 0 dS = \boxed{0}.$$

The two answers agree.

25. The surface together with its bounding curve is

The bounding curve C is the circle of radius 3 centered at the origin in the xy -plane; parametrize it in the counterclockwise direction by

$$\mathbf{r}(\theta) = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = y \mathbf{i} + x \mathbf{j} + x^2 \mathbf{k} = 3 \sin \theta \mathbf{i} + 3 \cos \theta \mathbf{j} + 9 \cos^2 \theta \mathbf{k}$$

so that the line integral is

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (3 \sin \theta \mathbf{i} + 3 \cos \theta \mathbf{j} + 9 \cos^2 \theta \mathbf{k}) \cdot (-3 \sin \theta \mathbf{i} + 3 \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} 3 (\cos^2 \theta - \sin^2 \theta) d\theta \\ &= \int_0^{2\pi} 3 \cos(2\theta) d\theta \\ &= \left[\frac{3}{2} \sin(2\theta) \right]_0^{2\pi} = \boxed{0}. \end{aligned}$$

26. The surface together with its bounding curve is

When $z = 4$, we have $4 = 10 - x^2 - y^2$, so that $x^2 + y^2 = 6$. Therefore the boundary of the surface is the circle $x^2 + y^2 = 6$ centered on the z -axis at $z = 4$. Parametrize it in the counterclockwise direction by

$$\mathbf{r}(\theta) = \sqrt{6} \cos \theta \mathbf{i} + \sqrt{6} \sin \theta \mathbf{j} + 4 \mathbf{k}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{F} = 4z \mathbf{i} + 3x \mathbf{j} + 3y \mathbf{k} = 16 \mathbf{i} + 3\sqrt{6} \cos \theta \mathbf{j} + 3\sqrt{6} \sin \theta \mathbf{k}$$

so that the line integral is

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} \left(16 \mathbf{i} + 3\sqrt{6} \cos \theta \mathbf{j} + 3\sqrt{6} \sin \theta \mathbf{k} \right) \cdot \left(-\sqrt{6} \sin \theta \mathbf{i} + \sqrt{6} \cos \theta \mathbf{j} \right) d\theta \\ &= \int_0^{2\pi} \left(-16\sqrt{6} \sin \theta + 18 \cos^2 \theta \right) d\theta \\ &= \int_0^{2\pi} \left(-16\sqrt{6} \sin \theta + 18 \left(\frac{1}{2} + \frac{1}{2} \cos(2\theta) \right) \right) d\theta \\ &= \left[16\sqrt{6} \cos \theta + 9\theta + \frac{9}{2} \sin(2\theta) \right]_0^{2\pi} = \boxed{18\pi}. \end{aligned}$$

27. The two surfaces are

Using Stokes' Theorem, note that

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y+z & z+x & x+y \end{vmatrix} = \mathbf{0},$$

so that

$$\oint_C [(y+z) dx + (z+x) dy + (x+y) dz] = \iint_S \mathbf{0} \cdot \mathbf{n} dS = 0.$$

Calculating directly, note that on the curve of intersection, $x+y=-z$, $y+z=-x$, and $x+z=-y$. Further, $x^2+y^2+z^2=1$ implies that $2x dx + 2y dy + 2z dz = 0$, so that $x dx + y dy + z dz = 0$. Therefore

$$\oint_C [(y+z) dx + (z+x) dy + (x+y) dz] = \oint_C (-x dx - y dy - z dz) = \oint_C 0 = \boxed{0}.$$

28. The two surfaces are

Using Stokes' Theorem, we can parametrize the portion of the plane inside the cylinder using cylindrical coordinates by

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (1 - r \cos \theta) \mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -\cos \theta \\ -r \sin \theta & r \cos \theta & r \sin \theta \end{vmatrix} = r \mathbf{i} + r \mathbf{k}.$$

Since this is upward-pointing, we use this normal. Further,

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y-z & z-x & x-y \end{vmatrix} = -2\mathbf{i} - 2\mathbf{j} - 2\mathbf{k}.$$

Then

$$\begin{aligned}
 \oint_C [(y-z) dx + (z-x) dy + (x-y) dz] &= \iint_S \mathbf{F} \cdot \mathbf{n} dS \\
 &= \int_0^1 \int_0^{2\pi} (-2\mathbf{i} - 2\mathbf{j} - 2\mathbf{k}) \cdot (r\mathbf{i} + r\mathbf{k}) d\theta dr \\
 &= \int_0^1 \int_0^{2\pi} (-4r) d\theta dr \\
 &= \int_0^1 (-8\pi r) dr \\
 &= [-4\pi r^2]_0^1 = -4\pi.
 \end{aligned}$$

To compute the line integral directly, use the same parametrization as above, but with $r = 1$ to get the boundary; then

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + (1 - \cos \theta) \mathbf{k}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\begin{aligned}
 \oint_C [(y-z) dx + (z-x) dy + (x-y) dz] &= \oint_C \mathbf{F} \cdot d\mathbf{r} \\
 &= \int_0^{2\pi} ((\sin \theta + \cos \theta - 1)\mathbf{i} + (1 - 2\cos \theta)\mathbf{j} + (\cos \theta - \sin \theta)\mathbf{k}) \\
 &\quad \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j} + \sin \theta \mathbf{k}) d\theta \\
 &= \int_0^{2\pi} (-2\sin^2 \theta + \sin \theta + \cos \theta - 2\cos^2 \theta) d\theta \\
 &= \int_0^{2\pi} (-2 + \sin \theta + \cos \theta) d\theta \\
 &= [-2\theta - \cos \theta + \sin \theta]_0^{2\pi} = \boxed{-4\pi}.
 \end{aligned}$$

29. The given curve is a circle of radius 2 centered on the z -axis, in the plane $z = 2$. Using Stokes' Theorem, we consider the disk in that plane that it bounds; we can parametrize that disk by

$$\mathbf{r}(r, \theta) = 2r \cos \theta \mathbf{i} + 2r \sin \theta \mathbf{j} + 2\mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi$$

Then

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2\cos \theta & 2\sin \theta & 0 \\ -2r\sin \theta & 2r\cos \theta & 0 \end{vmatrix} = 4r \mathbf{k}.$$

Since this is upward-pointing, we use this normal. Further,

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x & x+y & x+y+z \end{vmatrix} = \mathbf{i} - \mathbf{j} + \mathbf{k}.$$

Then

$$\begin{aligned}
 \oint_C [x dx + (x+y) dy + (x+y+z) dz] &= \iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} dS \\
 &= \int_0^1 \int_0^{2\pi} (\mathbf{i} - \mathbf{j} + \mathbf{k}) \cdot 4r \mathbf{k} d\theta dr \\
 &= \int_0^1 \int_0^{2\pi} 4r d\theta dr \\
 &= \int_0^1 [4r\theta]_0^{2\pi} dr \\
 &= \int_0^1 8\pi r dr \\
 &= [4\pi r^2]_0^1 = 4\pi.
 \end{aligned}$$

To compute the line integral directly, use the same parametrization as above, but with $r = 1$ to get the boundary; then as in the problem statement

$$\mathbf{r}(\theta) = 2 \cos \theta \mathbf{i} + 2 \sin \theta \mathbf{j} + 2 \mathbf{k}, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\begin{aligned}
 \oint_C [x dx + (x+y) dy + (x+y+z) dz] &= \oint_C \mathbf{F} \cdot d\mathbf{r} \\
 &= \int_0^{2\pi} (2 \cos \theta \mathbf{i} + (2 \cos \theta + 2 \sin \theta) \mathbf{j} + (2 \cos \theta + 2 \sin \theta + 2) \mathbf{k}) \\
 &\quad \cdot (-2 \sin \theta \mathbf{i} + 2 \cos \theta \mathbf{j}) d\theta \\
 &= \int_0^{2\pi} 4 \cos^2 \theta d\theta \\
 &= \int_0^{2\pi} (2 + 2 \cos(2\theta)) d\theta \\
 &= [2\theta + \sin(2\theta)]_0^{2\pi} = \boxed{4\pi}.
 \end{aligned}$$

30. The triangle is

We parametrize the triangle by

$$\mathbf{r}(x, y) = x \mathbf{i} + y \mathbf{j} + (1 - x - y) \mathbf{k}, \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1 - x.$$

Then

$$\mathbf{r}_x \times \mathbf{r}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -1 \\ 0 & 1 & -1 \end{vmatrix} = \mathbf{i} + \mathbf{j} + \mathbf{k}.$$

Since this is upward-pointing, we use this normal. Further,

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y^2 & z^2 & x^2 \end{vmatrix} = -2z \mathbf{i} - 2x \mathbf{j} - 2y \mathbf{k}.$$

Then

$$\begin{aligned} \oint_C [y^2 dx + z^2 dy + x^2 dz] &= \iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} dS \\ &= \int_0^1 \int_0^{1-x} (-2(1-x-y) \mathbf{i} - 2x \mathbf{j} - 2y \mathbf{k}) \cdot (\mathbf{i} + \mathbf{j} + \mathbf{k}) dy dx \\ &= \int_0^1 \int_0^{1-x} (-2) dy dx \\ &= \int_0^1 [-2y]_0^{1-x} dx \\ &= \int_0^1 2(x-1) dx \\ &= [(x-1)^2]_0^1 = -1. \end{aligned}$$

To compute the line integral directly, we parametrize the boundary using three separate curves:

$$\begin{aligned} C_1 : & \text{ from } (1, 0, 0) \text{ to } (0, 1, 0) & \mathbf{r}(t) &= (1-t) \mathbf{i} + t \mathbf{j}, \quad 0 \leq t \leq 1 \\ C_2 : & \text{ from } (0, 1, 0) \text{ to } (0, 0, 1) & \mathbf{r}(t) &= (1-t) \mathbf{j} + t \mathbf{k}, \quad 0 \leq t \leq 1 \\ C_3 : & \text{ from } (0, 0, 1) \text{ to } (1, 0, 0) & \mathbf{r}(t) &= t \mathbf{i} + (1-t) \mathbf{k}. \end{aligned}$$

Then

$$\begin{aligned} \oint_C (y^2 dx + z^2 dy + x^2 dz) &= \int_{C_1} (y^2 dx + z^2 dy + x^2 dz) + \int_{C_2} (y^2 dx + z^2 dy + x^2 dz) \\ &\quad + \int_{C_3} (y^2 dx + z^2 dy + x^2 dz) \\ &= \int_0^1 (t^2 \mathbf{i} + (1-t)^2 \mathbf{k}) \cdot (-\mathbf{i} + \mathbf{j}) dt + \int_0^1 ((1-t)^2 \mathbf{i} + t^2 \mathbf{j}) \cdot (-\mathbf{j} + \mathbf{k}) dt \\ &\quad + \int_0^1 ((1-t)^2 \mathbf{j} + t^2 \mathbf{k}) \cdot (\mathbf{i} - \mathbf{k}) dt \\ &= \int_0^1 (-t^2) dt + \int_0^1 (-t^2) dt + \int_0^1 (-t^2) dt \\ &= -3 \int_0^1 t^2 dt = -3 \left[\frac{1}{3} t^3 \right]_0^1 = \boxed{-1}. \end{aligned}$$

31. We have

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x & y & 0 \end{vmatrix} = \mathbf{0},$$

so that $\mathbf{F}$ is conservative, by the theorem in Objective 4.

32. We have

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & x & 0 \end{vmatrix} = \mathbf{0},$$

so that $\mathbf{F}$ is conservative, by the theorem in Objective 4.

33. We have

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xy & yz & zx \end{vmatrix} = -y\mathbf{i} - z\mathbf{j} - x\mathbf{k} \neq \mathbf{0},$$

so that $\mathbf{F}$ is not conservative, by the theorem in Objective 4.

34. We have

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ yz & zx & xy \end{vmatrix} = \mathbf{0},$$

so that $\mathbf{F}$ is conservative, by the theorem in Objective 4.

Applications and Extensions

35. $\mathbf{F}$ is conservative if and only if its curl is zero:

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{z}{y} & c\frac{xz}{y^2} & 0 \end{vmatrix} = (-x + 2cx)\mathbf{k}.$$

This is $\mathbf{0}$ if and only if $c = \frac{1}{2}$.

36. $\mathbf{F}$ is conservative if and only if its curl is zero:

$$\begin{aligned} \operatorname{curl} \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{z}{y} & c\frac{xz}{y^2} & \frac{x}{y} \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y} \left(\frac{x}{y} \right) - \frac{\partial}{\partial z} \left(c\frac{xz}{y^2} \right) \right) \mathbf{i} + \left(\frac{\partial}{\partial z} \left(\frac{z}{y} \right) - \frac{\partial}{\partial x} \left(\frac{x}{y} \right) \right) \mathbf{j} + \left(\frac{\partial}{\partial x} \left(c\frac{xz}{y^2} \right) - \frac{\partial}{\partial y} \left(\frac{z}{y} \right) \right) \mathbf{k} \\ &= \left(-\frac{x}{y^2} - c\frac{x}{y^2} \right) \mathbf{i} + \left(\frac{1}{y} - \frac{1}{y} \right) \mathbf{j} + \left(c\frac{z}{y^2} + \frac{z}{y^2} \right) \mathbf{k}. \end{aligned}$$

This is $\mathbf{0}$ if and only if $c = -1$.

37. Let $\mathbf{F} = f_1\mathbf{i} + f_2\mathbf{j} + f_3\mathbf{k}$ and $\mathbf{G} = g_1\mathbf{i} + g_2\mathbf{j} + g_3\mathbf{k}$. Then

$$\mathbf{F} + \mathbf{G} = (f_1 + g_1)\mathbf{i} + (f_2 + g_2)\mathbf{j} + (f_3 + g_3)\mathbf{k},$$

so that

$$\begin{aligned} \operatorname{curl}(\mathbf{F} + \mathbf{G}) &= \left(\frac{\partial}{\partial y}(f_3 + g_3) - \frac{\partial}{\partial z}(f_2 + g_2) \right) \mathbf{i} - \left(\frac{\partial}{\partial x}(f_3 + g_3) - \frac{\partial}{\partial z}(f_1 + g_1) \right) \mathbf{j} \\ &\quad + \left(\frac{\partial}{\partial x}(f_2 + g_2) - \frac{\partial}{\partial y}(f_1 + g_1) \right) \mathbf{k} \\ &= \left(\frac{\partial f_3}{\partial y} - \frac{\partial f_2}{\partial z} \right) \mathbf{i} - \left(\frac{\partial f_3}{\partial x} - \frac{\partial f_1}{\partial z} \right) \mathbf{j} + \left(\frac{\partial f_2}{\partial x} - \frac{\partial f_1}{\partial y} \right) \mathbf{k} \\ &\quad + \left(\frac{\partial g_3}{\partial y} - \frac{\partial g_2}{\partial z} \right) \mathbf{i} - \left(\frac{\partial g_3}{\partial x} - \frac{\partial g_1}{\partial z} \right) \mathbf{j} + \left(\frac{\partial g_2}{\partial x} - \frac{\partial g_1}{\partial y} \right) \mathbf{k} \\ &= \operatorname{curl} \mathbf{F} + \operatorname{curl} \mathbf{G}. \end{aligned}$$

38. Let $\mathbf{F} = f_1 \mathbf{i} + f_2 \mathbf{j} + f_3 \mathbf{k}$. Then

$$c\mathbf{F} = (cf_1)\mathbf{i} + (cf_2)\mathbf{j} + (cf_3)\mathbf{k},$$

so that

$$\begin{aligned} \operatorname{curl}(c\mathbf{F}) &= \left(\frac{\partial}{\partial y}(cf_3) - \frac{\partial}{\partial z}(cf_2) \right) \mathbf{i} - \left(\frac{\partial}{\partial x}(cf_3) - \frac{\partial}{\partial z}(cf_1) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(cf_2) - \frac{\partial}{\partial y}(cf_1) \right) \mathbf{k} \\ &= c \left(\frac{\partial f_3}{\partial y} - \frac{\partial f_2}{\partial z} \right) \mathbf{i} - c \left(\frac{\partial f_3}{\partial x} - \frac{\partial f_1}{\partial z} \right) \mathbf{j} + c \left(\frac{\partial f_2}{\partial x} - \frac{\partial f_1}{\partial y} \right) \mathbf{k} \\ &= c \operatorname{curl} \mathbf{F}. \end{aligned}$$

39. Parametrize the hemisphere using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = \cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \frac{\pi}{2}.$$

Then

$$\mathbf{r}_\phi \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta \cos \phi & \sin \theta \cos \phi & -\sin \phi \\ -\sin \theta \sin \phi & \cos \theta \sin \phi & 0 \end{vmatrix} = \cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}.$$

This is upward-pointing in the given range of ϕ , so after normalization, it is the normal we want. Then

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} dS &= \int_0^{2\pi} \int_0^{\pi/2} (\cos \phi \mathbf{i} + \cos \theta \sin \phi \mathbf{j} + \sin \theta \sin \phi \mathbf{k}) \\ &\quad \cdot \frac{1}{\|\mathbf{r}_\phi \times \mathbf{r}_\theta\|} (\cos \theta \sin^2 \phi \mathbf{i} + \sin \theta \sin^2 \phi \mathbf{j} + \sin \phi \cos \phi \mathbf{k}) \\ &\quad \cdot \|\mathbf{r}_\phi \times \mathbf{r}_\theta\| d\phi d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/2} (\cos \theta \sin^2 \phi \cos \phi + \sin \theta \cos \theta \sin^3 \phi + \sin \theta \sin^2 \phi \cos \phi) d\phi d\theta \\ &= \int_0^{\pi/2} \int_0^{2\pi} (\cos \theta \sin^2 \phi \cos \phi + \sin \theta \cos \theta \sin^3 \phi + \sin \theta \sin^2 \phi \cos \phi) d\theta d\phi \\ &= \int_0^{\pi/2} \left[\sin \theta \sin^2 \phi \cos \phi + \frac{1}{2} \sin^2 \theta \sin^3 \phi - \cos \theta \sin^2 \phi \cos \phi \right]_0^{2\pi} d\phi \\ &= \boxed{0}. \end{aligned}$$

40. Parametrize the unit disk via

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 0 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = r \mathbf{k}.$$

Since this is an upward-pointing normal, we use this normal. Then

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} dS &= \int_0^1 \int_0^{2\pi} (r \cos \theta \mathbf{j} + r \sin \theta \mathbf{k}) \cdot r \mathbf{k} d\theta dr \\ &= \int_0^1 \int_0^{2\pi} r^2 \sin \theta d\theta dr \\ &= \int_0^1 [-r^2 \cos \theta]_0^{2\pi} dr = \boxed{0}. \end{aligned}$$

Note that the answers to Problems 38 and 39 are the same. In fact, $\mathbf{F} = \operatorname{curl}(xz \mathbf{i} + xy \mathbf{j} + xz \mathbf{k})$, so the comment after Example 3 ensures that the two integrals will be equal.

41. Computing $\text{curl } \mathbf{F}$ gives

$$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & -x & z \end{vmatrix} = -2\mathbf{k}.$$

Since the curl is nonzero, the vector field is not conservative. To find a path closed path C on which the line integral is zero, note that by Stokes' Theorem

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S \text{curl } \mathbf{F} \cdot \mathbf{n} dS = \iint_S (-2\mathbf{k}) \cdot \mathbf{n} dS,$$

so that any surface whose normal has no $\mathbf{k}$ component will suffice. So for example we can choose the square with vertices $(0, 0, 0)$, $(0, 1, 0)$, $(0, 1, 1)$, and $(0, 0, 1)$; it is parametrized as

$$\mathbf{r}(y, z) = y\mathbf{j} + z\mathbf{k}, \quad 0 \leq y \leq 1, \quad 0 \leq z \leq 1,$$

so that its normal is

$$\mathbf{r}_y \times \mathbf{r}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{vmatrix} = \mathbf{i}.$$

Then $\text{curl } \mathbf{F} \cdot \mathbf{n} = 0$, so the path forming the boundary of this square is a path along which the line integral is zero.

42. Since

$$\text{curl } \mathbf{F} = \left(\frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z} \right) \mathbf{i} - \left(\frac{\partial R}{\partial x} - \frac{\partial P}{\partial z} \right) \mathbf{j} + \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \mathbf{k},$$

we have

$$\begin{aligned} \text{div curl } \mathbf{F} &= \frac{\partial}{\partial x} \left(\frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z} \right) - \frac{\partial}{\partial y} \left(\frac{\partial R}{\partial x} - \frac{\partial P}{\partial z} \right) + \frac{\partial}{\partial z} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \\ &= R_{xy} - Q_{xz} - R_{yx} + P_{yz} + Q_{zx} - P_{zy} = 0 \end{aligned}$$

since mixed partials are equal (because the functions are twice differentiable with continuous derivatives).

43. (a) Let $\mathbf{F} = P\mathbf{i} + Q\mathbf{j} + R\mathbf{k}$ be a vector field with continuous and differentiable components. Suppose $Q_x = P_y$, $R_y = Q_z$, and $P_z = R_x$. Then

$$\text{curl } \mathbf{F} = (R_y - Q_z)\mathbf{i} - (R_x - P_z)\mathbf{j} + (Q_x - P_y)\mathbf{k} = \mathbf{0},$$

which implies that $\mathbf{F}$ is the gradient of some function. Therefore $\mathbf{F}$ is a gradient field.

(b) Answers will vary.

44. Here

$$P(x, y, z) = yz - y - z, \quad Q(x, y, z) = xz - x - z, \quad R(x, y, z) = xy - x - y,$$

so that

$$\begin{aligned} P_y &= z - 1, & Q_x &= z - 1, & R_x &= y - 1, \\ P_z &= y - 1, & Q_z &= x - 1, & R_y &= x - 1. \end{aligned}$$

Then $Q_x = P_y$, $R_y = Q_z$, and $R_x = P_z$, so by Problem 43, the given integral is independent of the path.

45. Here

$$P(x, y, z) = x + y, \quad Q(x, y, z) = x - z, \quad R(x, y, z) = z - y,$$

so that

$$\begin{aligned} P_y &= 1, & Q_x &= 1, & R_x &= 0, \\ P_z &= 0, & Q_z &= -1, & R_y &= -1. \end{aligned}$$

Then $Q_x = P_y$, $R_y = Q_z$, and $R_x = P_z$, so by Problem 43, the given integral is independent of the path. To find the value of the integral, parametrize the path as

$$\mathbf{r}(t) = at\mathbf{i} + bt\mathbf{j} + ct\mathbf{k}, \quad 0 \leq t \leq 1.$$

Then the work performed is

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^1 ((at + bt)\mathbf{i} + (at - ct)\mathbf{j} + (ct - bt)\mathbf{k}) \cdot (a\mathbf{i} + b\mathbf{j} + c\mathbf{k}) \, dt \\ &= \int_0^1 (a^2 + ab + ab - bc + c^2 - bc)t \, dt \\ &= (a^2 + 2ab - 2bc + c^2) \int_0^1 t \, dt \\ &= (a^2 + 2ab - 2bc + c^2) \left[\frac{1}{2}t^2 \right]_0^1 \\ &= \boxed{\frac{a^2 + 2ab - 2bc + c^2}{2}}. \end{aligned}$$

46. By Problem 42, if the given vector field is $\text{curl } \mathbf{F}$ for some vector field $\mathbf{F}$, then

$$\text{div curl } \mathbf{F} = \text{div}(x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) = 0.$$

But in fact

$$\text{div}(x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) = \frac{\partial x}{\partial x} + \frac{\partial y}{\partial y} + \frac{\partial z}{\partial z} = 3 \neq 0.$$

Therefore the given vector field is not the curl of any twice-differentiable vector field.

Challenge Problems

47. The simplest argument is to apply Stokes' Theorem directly to the surface of the sphere. Since the boundary of the sphere is the empty curve, the line integral around that curve is zero. Alternatively, consider the diagram

Denote the upper hemisphere by U and the lower by L . Then

$$\iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS = \iint_U \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS + \iint_L \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS.$$

Applying Stokes' Theorem to each piece, we see that each boundary curve is the unit circle C in the xy -plane. However, the direction of the parametrization for U is determined (see the discussion in Objective 1) by walking around the circle so that the surface is on your left, which is counter-clockwise; for L , keeping the surface on your left results in a clockwise parametrization. So the two parametrizations have derivatives that are negatives of each other, so that

$$\iint_U \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS + \iint_L \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS = \oint_C \mathbf{F} \cdot d\mathbf{r} + \oint_C \mathbf{F} \cdot (-d\mathbf{r}) = 0.$$

48. The conditions on E , S , and $\mathbf{F}$ ensure that the Divergence Theorem applies, so that

$$\iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_E \operatorname{div} \operatorname{curl} \mathbf{F} \, dV.$$

But by Problem 42, $\operatorname{div} \operatorname{curl} \mathbf{F} = 0$, so the integral is zero.

49. The conditions of the problem statement ensure that Stokes' Theorem applies. Then

$$\begin{aligned} \operatorname{curl}(f\nabla g) &= \operatorname{curl} \left(f \frac{\partial g}{\partial x} \mathbf{i} + f \frac{\partial g}{\partial y} \mathbf{j} + f \frac{\partial g}{\partial z} \mathbf{k} \right) \\ &= \left(\frac{\partial}{\partial y} \left(f \frac{\partial g}{\partial z} \right) - \frac{\partial}{\partial z} \left(f \frac{\partial g}{\partial y} \right) \right) \mathbf{i} - \left(\frac{\partial}{\partial x} \left(f \frac{\partial g}{\partial z} \right) - \frac{\partial}{\partial z} \left(f \frac{\partial g}{\partial x} \right) \right) \mathbf{j} \\ &\quad + \left(\frac{\partial}{\partial x} \left(f \frac{\partial g}{\partial y} \right) - \frac{\partial}{\partial y} \left(f \frac{\partial g}{\partial x} \right) \right) \mathbf{k}. \end{aligned}$$

Computing the derivatives above gives:

$$\begin{aligned} \frac{\partial}{\partial y} \left(f \frac{\partial g}{\partial z} \right) &= f_y g_z + f g_{yz}, & \frac{\partial}{\partial z} \left(f \frac{\partial g}{\partial y} \right) &= f_z g_y + f g_{zy}, \\ \frac{\partial}{\partial x} \left(f \frac{\partial g}{\partial z} \right) &= f_x g_z + f g_{xz}, & \frac{\partial}{\partial z} \left(f \frac{\partial g}{\partial x} \right) &= f_z g_x + f g_{zx}, \\ \frac{\partial}{\partial x} \left(f \frac{\partial g}{\partial y} \right) &= f_x g_y + f g_{xy}, & \frac{\partial}{\partial y} \left(f \frac{\partial g}{\partial x} \right) &= f_y g_x + f g_{yx}. \end{aligned}$$

Therefore, since mixed partials are equal,

$$\begin{aligned} \operatorname{curl}(f\nabla g) &= (f_y g_z - f_z g_y) \mathbf{i} - (f_x g_z - f_z g_x) \mathbf{j} + (f_x g_y - f_y g_x) \mathbf{k} \\ &= (f_x \mathbf{i} + f_y \mathbf{j} + f_z \mathbf{k}) \times (g_x \mathbf{i} + g_y \mathbf{j} + g_z \mathbf{k}) \\ &= \nabla f \times \nabla g. \end{aligned}$$

Then by Stokes' Theorem,

$$\int_C (f\nabla g) \cdot d\mathbf{r} = \iint_S \operatorname{curl}(f\nabla g) \cdot \mathbf{n} \, dS = \iint_S (\nabla f \times \nabla g) \cdot \mathbf{n} \, dS.$$

Chapter Review

1. The vector field is

2. The vector field is

3. Since $y = x^2$, we have $dy = 2x \, dx$. The range of integration is from $x = 1$ to $x = 2$. Therefore we get

$$\int_C \left(\frac{dx}{y} + \frac{dy}{x} \right) = \int_1^2 \left(\frac{dx}{x^2} + \frac{2x \, dx}{x} \right) = \int_1^2 \left(\frac{1}{x^2} + 2 \right) dx = \left[-\frac{1}{x} + 2x \right]_1^2 = \boxed{\frac{5}{2}}.$$

4. With the given parametrization, we have

$$dx = 2t \, dt, \quad dy = 3t^2 \, dt,$$

so that

$$\int_C [y \cos(xy) \, dx + x \cos(xy) \, dy] = \int_0^1 [t^3 \cos(t^2 \cdot t^3) \cdot 2t + t^2 \cos(t^2 \cdot t^3) \cdot 3t^2] \, dt = \int_0^1 5t^4 \cos(t^5) \, dt.$$

Now use the substitution $u = t^5$, so that $du = 5t^4 dt$; then $t = 0$ corresponds to $u = 0$ and $t = 1$ to $u = 1$, so the integral becomes

$$\int_0^1 5t^4 \cos(t^5) dt = \int_0^1 \cos u du = [\sin u]_0^1 = \boxed{\sin 1}.$$

5. (a) Since $P(x, y) = y \cos(xy)$ and $Q(x, y) = x \cos(xy)$ are continuous with continuous derivatives everywhere in the plane, to see if the vector field is conservative we must check if $\frac{\partial Q}{\partial x} = \frac{\partial P}{\partial y}$:

$$\frac{\partial Q}{\partial x} = \frac{\partial}{\partial x}(x \cos(xy)) = \cos(xy) - xy \sin(xy), \quad \frac{\partial P}{\partial y} = \frac{\partial}{\partial y}(y \cos(xy)) = \cos(xy) - xy \sin(xy).$$

Since the partials are equal, this vector field is conservative so the integral is independent of path.

- (b) The given path goes from $(0, 0)$ to $(1, 1)$, as does the path in Problem 4. Since the vector fields are the same, we conclude that the value of the integral along the right-angle path is the same as the integral in Problem 4, or $\boxed{\sin 1}$.

6. (a) First integrate $P(x, y) = y \cos(xy)$ with respect to x :

$$\int P(x, y) dx = \int y \cos(xy) dx = y \cdot \frac{1}{y} \sin(xy) + h(y) = \sin(xy) + h(y).$$

Then the y -derivative of this expression must be equal to $Q(x, y)$, so that

$$\frac{\partial}{\partial y}(\sin(xy) + h(y)) = x \cos(xy) + h'(y) = Q(x, y) = x \cos(xy),$$

so that $h'(y) = 0$. Therefore $h(y) = C$ for an arbitrary constant C , so that $\boxed{f(x, y) = \sin(xy) + C}$.

- (b) By the Fundamental Theorem of Line Integrals, the value of the integral along any path is the difference of the value of f at the two endpoints, so that in this case we get $f(1, 1) - f(0, 0) = \sin 1 - \sin 0 = \boxed{\sin 1}$.

7. With the given parametrization, we have

$$dx = dt, \quad dy = 2t dt, \quad dz = 3t^2 dt,$$

so that

$$\begin{aligned} \int_C [(yz - y - z) dx + (xz - x - z) dy + (xy - x - y) dz] \\ &= \int_0^1 [(t^2 \cdot t^3 - t^2 - t^3) dt + (t \cdot t^3 - t - t^3) \cdot 2t dt + (t \cdot t^2 - t - t^2) \cdot 3t^2 dt] \\ &= \int_0^1 (6t^5 - 5t^4 - 4t^3 - 3t^2) dt \\ &= [t^6 - t^5 - t^4 - t^3]_0^1 = \boxed{-2}. \end{aligned}$$

8. Parametrize the line segment by

$$\mathbf{r}(t) = t \mathbf{i} - 2t \mathbf{j} + 3t \mathbf{k}, \quad 0 \leq t \leq 1,$$

so that $\mathbf{r}_t = \mathbf{i} - 2\mathbf{j} + 3\mathbf{k}$. Then

$$\begin{aligned} \int_C \mathbf{F} \cdot \mathbf{r} &= \int_0^1 (t \cdot (-2t) \mathbf{i} + t \cdot 3t \mathbf{j} + (-2t - t) \mathbf{k}) \cdot (\mathbf{i} - 2\mathbf{j} + 3\mathbf{k}) dt \\ &= \int_0^1 (-2t^2 - 6t^2 - 9t) dt \\ &= \int_0^1 (-8t^2 - 9t) dt \\ &= \left[-\frac{8}{3}t^3 - \frac{9}{2}t^2 \right]_0^1 = \boxed{-\frac{43}{6}}. \end{aligned}$$

9. (a) We have

$$\nabla f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} = 6x \mathbf{i} + \mathbf{j} = \mathbf{F}(x, y).$$

- (b) By the Fundamental Theorem of Line Integrals, we have

$$\int_C (6x \, dx + dy) = f(6, 3) - f(4, 1) = (3 \cdot 6^2 + 3 - 2) - (3 \cdot 4^2 + 1 - 2) = \boxed{62}.$$

10. We are given that $\nabla(e^x \sin y) = e^x \sin y \mathbf{i} + e^x \cos y \mathbf{j}$, so the vector field we are integrating is conservative. Write $f(x, y) = e^x \sin y$. Then by the Fundamental Theorem of Line Integrals

$$\int_C (e^x \sin y \, dx + e^x \cos y \, dy) = f(1, 1) - f(0, 0) = e^1 \sin 1 - e^0 \sin 0 = \boxed{e \sin 1}.$$

11. The mass is given by the line integral of the density function along the wire; the density function is $\rho(t) = x + 1 = \cos t + 1$. Therefore the mass is

$$\begin{aligned} \int_C \rho(x, y) \, ds &= \int_0^{3\pi/4} (x + 1) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} \, dt \\ &= \int_0^{3\pi/4} (\cos t + 1) \sqrt{(-\sin t)^2 + \cos^2 t} \, dt \\ &= \int_0^{3\pi/4} (\cos t + 1) \, dt \\ &= [\sin t + t]_0^{3\pi/4} \\ &= \frac{3\pi}{4} + \sin \frac{3\pi}{4} = \boxed{\frac{3\pi}{4} + \frac{\sqrt{2}}{2}}. \end{aligned}$$

12. (a) Parametrize the line segment by $x = 1 + t$, $y = 1 + 3t$, $0 \leq t \leq 1$. Then $dx = dt$ and $dy = 3 \, dt$, so

$$\begin{aligned} \int_C (x^3 \, dx + y^3 \, dy) &= \int_0^1 ((1+t)^3 + (1+3t)^3 \cdot 3) \, dt \\ &= \int_0^1 ((1+t)^3 + 3(1+3t)^3) \, dt \\ &= \left[\frac{1}{4}(1+t)^4 + \frac{1}{4}(1+3t)^4 \right]_0^1 \\ &= (4 + 64) - \left(\frac{1}{4} + \frac{1}{4} \right) = \boxed{\frac{135}{2}}. \end{aligned}$$

- (b) Parametrize the three line segments as follows:

$$\begin{aligned} C_1, \text{ from } (1, 1) \text{ to } (1, 5): & \quad x = 1, \, y = 1 + 4t, \, 0 \leq t \leq 1, \quad dx = 0, \, dy = 4 \, dt \\ C_2, \text{ from } (1, 5) \text{ to } (2, 3): & \quad x = 1 + t, \, y = 5 - 2t, \, 0 \leq t \leq 1, \quad dx = dt, \, dy = -2 \, dt \\ C_3, \text{ from } (2, 3) \text{ to } (2, 4): & \quad x = 2, \, y = 3 + t, \, 0 \leq t \leq 1, \quad dx = 0, \, dy = dt. \end{aligned}$$

Then

$$\begin{aligned}
 \int_C (x^3 dx + y^3 dy) &= \int_{C_1} (x^3 dx + y^3 dy) + \int_{C_2} (x^3 dx + y^3 dy) + \int_{C_3} (x^3 dx + y^3 dy) \\
 &= \int_0^1 (1+4t)^3 \cdot 4 dt + \int_0^1 ((1+t)^3 + (5-2t)^3 \cdot (-2)) dt \\
 &\quad + \int_0^1 (3+t)^3 \cdot 1 dt \\
 &= \int_0^1 4(1+4t)^3 dt + \int_0^1 ((1+t)^3 - 2(5-2t)^3) dt + \int_0^1 (3+t)^3 dt \\
 &= \left[\frac{1}{4}(1+4t)^4 + \frac{1}{4}(1+t)^4 + \frac{1}{4}(5-2t)^4 + \frac{1}{4}(3+t)^4 \right]_0^1 \\
 &= \left(\frac{625}{4} + 4 + \frac{81}{4} + 64 \right) - \left(\frac{1}{4} + \frac{1}{4} + \frac{625}{4} + \frac{81}{4} \right) \\
 &= \boxed{\frac{135}{2}}.
 \end{aligned}$$

(c) Parametrize the parabolic piece by $x = t$, $y = t^2$, $1 \leq t \leq 2$; then $dx = dt$ and $dy = 2t dt$, so

$$\begin{aligned}
 \int_C (x^3 dx + y^3 dy) &= \int_1^2 (t^3 \cdot 1 + t^6 \cdot 2t) dt \\
 &= \int_1^2 (t^3 + 2t^7) dt \\
 &= \left[\frac{1}{4}t^4 + \frac{1}{4}t^8 \right]_1^2 \\
 &= (4 + 64) - \left(\frac{1}{4} + \frac{1}{4} \right) = \boxed{\frac{135}{2}}.
 \end{aligned}$$

13. Parametrize the lamina using cylindrical coordinates; then

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + r \mathbf{k}, \quad 1 \leq r \leq 4, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\begin{aligned}
 \mathbf{r}_r &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + \mathbf{k}, \quad \mathbf{r}_\theta = -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j} \\
 \mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 1 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = -r \cos \theta \mathbf{i} - r \sin \theta \mathbf{j} + r \mathbf{k} \\
 \|\mathbf{r}_r \times \mathbf{r}_\theta\| &= \sqrt{r^2 \cos^2 \theta + r^2 \sin^2 \theta + r^2} = r\sqrt{2}.
 \end{aligned}$$

Then the mass of the lamina is the integral of the mass density function over the surface, so it is

$$\begin{aligned}
 M &= \iint_S \rho(x, y, z) dS = \int_1^4 \int_0^{2\pi} r^2 \cdot \|\mathbf{r}_r \times \mathbf{r}_\theta\| d\theta dr \\
 &= \int_1^4 \int_0^{2\pi} r^3 \sqrt{2} d\theta dr \\
 &= \int_1^4 2\pi \sqrt{2} r^3 dr \\
 &= \left[\frac{1}{2} \pi \sqrt{2} r^4 \right]_1^4 = \boxed{\frac{255}{2} \sqrt{2} \pi}.
 \end{aligned}$$

14. Parametrize the curve by $y = t$, $x = t^2$ for $0 \leq t \leq 1$; then $dy = dt$ and $dx = 2t dt$, so

$$\begin{aligned}\int_C (x^2 y^3 dx - xy^4 dy) &= \int_0^1 (t^4 t^3 \cdot 2t - t^2 t^4) dt \\ &= \int_0^1 (2t^8 - t^6) dt \\ &= \left[\frac{2}{9} t^9 - \frac{1}{7} t^7 \right]_0^1 = \boxed{\frac{5}{63}}.\end{aligned}$$

15. With the given parametrization, we have $dx = -\sin t dt$ and $dy = \cos t dt$, so that

$$\begin{aligned}\int_C x^2 y^2 ds &= \int_0^\pi \cos^2 t \sin^2 t \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= \int_0^\pi \cos^2 t \sin^2 t \sqrt{\sin^2 t + \cos^2 t} dt \\ &= \int_0^\pi \cos^2 t \sin^2 t dt \\ &= \int_0^\pi \frac{1}{4} \sin^2(2t) dt \\ &= \frac{1}{4} \int_0^\pi \left(\frac{1}{2} - \frac{1}{2} \cos(4t) \right) dt \\ &= \frac{1}{4} \left[\frac{1}{2} t - \frac{1}{8} \sin(4t) \right]_0^\pi \\ &= \boxed{\frac{\pi}{8}}.\end{aligned}$$

16. Since the given vector field is discontinuous at the origin, we must compute the line integral. We can parametrize the unit circle C as

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then $(x^2 + y^2)^{3/2} = 1$, so the work done is

$$\begin{aligned}\oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\sin \theta \mathbf{i} - \cos \theta \mathbf{j}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) d\theta \\ &= \int_0^{2\pi} (-\sin^2 \theta - \cos^2 \theta) d\theta \\ &= \int_0^{2\pi} (-1) d\theta = \boxed{-2\pi}.\end{aligned}$$

17. Parametrize the curve by $\mathbf{r}(t) = t \mathbf{i} + \sin t \mathbf{j}$ for $0 \leq t \leq 2\pi$. Then the work is

$$\begin{aligned}\int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\sin^2 t \mathbf{i} + \sin t \mathbf{j}) \cdot (\mathbf{i} + \cos t \mathbf{j}) dt \\ &= \int_0^{2\pi} (\sin^2 t + \sin t \cos t) dt \\ &= \int_0^{2\pi} \left(\frac{1}{2} - \frac{1}{2} \cos(2t) + \sin t \cos t \right) dt \\ &= \left[\frac{1}{2} t - \frac{1}{4} \sin(2t) + \frac{1}{2} \sin^2 t \right]_0^{2\pi} = \boxed{\pi}.\end{aligned}$$

18. The given vector field is conservative. To see this, start by integrating $\frac{x}{x^2+y^2}$ with respect to x , using the substitution $x^2 + y^2 = u$:

$$\int \frac{x}{x^2 + y^2} dx = \frac{1}{2} \int \frac{1}{u} du = \frac{1}{2} \ln |u| + C = \frac{1}{2} \ln(x^2 + y^2) + h(y).$$

Differentiating this expression and setting it equal to $\frac{y}{x^2+y^2}$ gives

$$\frac{\partial}{\partial y} \left(\frac{1}{2} \ln(x^2 + y^2) + h(y) \right) = \frac{y}{x^2 + y^2} + h'(y) = \frac{y}{x^2 + y^2},$$

so that $h'(y) = 0$ and therefore $h(y) = C$ for an arbitrary constant C . So $\mathbf{F} = \nabla f$ where $f(x, y)$ is (taking $C = 0$) $f(x, y) = \frac{1}{2} \ln(x^2 + y^2)$. Then by the Fundamental Theorem of Line Integrals, the work done in moving the object along the given curve is

$$f(2\pi, 0) - f(-\pi, 0) = \frac{1}{2} \ln(4\pi^2) - \frac{1}{2} \ln(\pi^2) = \ln 2 + \ln \pi - \ln \pi = \boxed{\ln 2}.$$

19. The region is

The lower curve is $t^2 + 3$, since that is an upward-opening parabola. The two curves intersect where $t^2 + 3 = 30 - 2t^2$, or $3t^2 = 27$. So they intersect when $t = \pm 3$ (which corresponds to the points $(\pm 3, 12)$). To determine the area, we compute the line integral around the boundary in a counterclockwise direction, so we walk along $t^2 + 3$ from $t = -3$ to $t = 3$, and then along $30 - 2t^2$ from $t = 3$ to $t = -3$. For $t^2 + 3$, we have $dx = dt$ and $dy = 2t dt$, while for $30 - 2t^2$ we have $dx = dt$ and $dy = -4t dt$. Using Green's formula for area, then, the area is

$$\begin{aligned} A &= \frac{1}{2} \int_{C_{\text{lower}}} (-y dx + x dy) + \frac{1}{2} \int_{C_{\text{higher}}} (-y dx + x dy) \\ &= \frac{1}{2} \int_{-3}^3 (-(t^2 + 3) + t \cdot 2t) dt + \frac{1}{2} \int_3^{-3} (-(30 - 2t^2) + t \cdot (-4t)) dt \\ &= \frac{1}{2} \int_{-3}^3 (t^2 - 3) dt + \frac{1}{2} \int_3^{-3} (-2t^2 - 30) dt \\ &= \frac{1}{2} \left[\frac{1}{3} t^3 - 3t \right]_{-3}^3 + \frac{1}{2} \left[-\frac{2}{3} t^3 - 30t \right]_3^{-3} \\ &= 0 + 108 = \boxed{108}. \end{aligned}$$

20. The parallelogram is

The lower edge of the parallelogram passes through $(0, 0)$ and $(2, 1)$, so it has the equation $y = \frac{1}{2}x$. The upper edge passes through $(0, 5)$ and $(2, 6)$, so its equation is $y = 5 + \frac{1}{2}x$. Since both $P(x, y) = \ln(1 + y)$ and $Q(x, y) = \frac{xy}{1+y}$ are continuous and differentiable for $y > -1$, Green's Theorem applies, so that

$$\begin{aligned}
 \int_C \left[\ln(1 + y) dx + \frac{xy}{1 + y} dy \right] &= \iint_R \left(\frac{\partial}{\partial x} \left(\frac{xy}{1 + y} \right) - \frac{\partial}{\partial y} (\ln(1 + y)) \right) dx dy \\
 &= \int_0^2 \int_{x/2}^{5+x/2} \left(\frac{y}{1 + y} - \frac{1}{1 + y} \right) dy dx \\
 &= \int_0^2 \int_{x/2}^{5+x/2} \left(\frac{1 + y}{1 + y} - \frac{1}{1 + y} - \frac{1}{1 + y} \right) dy dx \\
 &= \int_0^2 \int_{x/2}^{5+x/2} \left(1 - \frac{2}{1 + y} \right) dy dx \\
 &= \int_0^2 [y - 2 \ln(1 + y)]_{x/2}^{5+x/2} dx \\
 &= \int_0^2 \left(5 - 2 \ln \left(6 + \frac{x}{2} \right) + 2 \ln \left(1 + \frac{x}{2} \right) \right) dx \\
 &= \int_0^2 \left(5 - 2 \ln \frac{1}{2} - 2 \ln(12 + x) + 2 \ln \frac{1}{2} + 2 \ln(2 + x) \right) dx \\
 &= \int_0^2 (5 - 2 \ln(12 + x) + 2 \ln(2 + x)) dx.
 \end{aligned}$$

To integrate $\ln(12 + x)$ and $\ln(2 + x)$, use Formula 118 in the endnotes together with the substitution $u = 12 + x$ or $u = 2 + x$. For example,

$$\int \ln(12 + x) dx = \int \ln u du = u \ln u - u + C = (12 + x) \ln(12 + x) - (12 + x) + C.$$

Similarly, $\int \ln(2+x) dx = (2+x) \ln(2+x) - (2+x) + C$. So the integral above is

$$\begin{aligned}
 \int_0^2 (5 - 2 \ln(12+x) + 2 \ln(2+x)) dx \\
 &= [5x - 2((12+x) \ln(12+x) - (12+x)) + 2((2+x) \ln(2+x) - (2+x))]_0^2 \\
 &= [5x + 20 - 2(12+x) \ln(12+x) + 2(2+x) \ln(2+x)]_0^2 \\
 &= (10 + 20 - 28 \ln 14 + 8 \ln 4) - (0 + 20 - 24 \ln 12 + 4 \ln 2) \\
 &= 10 - 28 \ln 7 - 28 \ln 2 + 16 \ln 2 + 48 \ln 2 + 24 \ln 3 - 4 \ln 2 \\
 &= \boxed{10 - 28 \ln 7 + 32 \ln 2 + 24 \ln 3}.
 \end{aligned}$$

21. Parametrize the four edges of the square as follows:

$$\begin{aligned}
 C_1 : (0,0) \rightarrow (1,0) : \quad x &= t, \ y = 0, \quad 0 \leq t \leq 1, \quad dx = dt, \ dy = 0 \\
 C_2 : (1,0) \rightarrow (1,1) : \quad x &= 1, \ y = t, \quad 0 \leq t \leq 1, \quad dx = 0, \ dy = dt \\
 C_3 : (1,1) \rightarrow (0,1) : \quad x &= 1-t, \ y = 1, \quad 0 \leq t \leq 1, \quad dx = -dt, \ dy = 0 \\
 C_4 : (0,1) \rightarrow (0,0) : \quad x &= 0, \ y = 1-t, \quad 0 \leq t \leq 1, \quad dx = 0, \ dy = -dt.
 \end{aligned}$$

Then the line integral is the sum of the line integrals on each piece:

$$\begin{aligned}
 \oint_C (y^2 dx - x^2 dy) &= \int_{C_1} (y^2 dx - x^2 dy) + \int_{C_2} (y^2 dx - x^2 dy) \\
 &\quad + \int_{C_3} (y^2 dx - x^2 dy) + \int_{C_4} (y^2 dx - x^2 dy) \\
 &= \int_0^1 0 dt + \int_0^1 (-1) dt + \int_0^1 (-1) dt + \int_0^1 0 dt \\
 &= -\int_0^1 1 dt - \int_0^1 1 dt = \boxed{-2}.
 \end{aligned}$$

22. Since the component functions $P(x, y) = y^2$ and $Q(x, y) = -x^2$ are continuous and differentiable everywhere, Green's Theorem applies, and

$$\begin{aligned}
 \oint_C (y^2 dx - x^2 dy) &= \iint_R \left(\frac{\partial}{\partial x}(-x^2) - \frac{\partial}{\partial y}(y^2) \right) dx dy \\
 &= \int_0^1 \int_0^1 (-2x - 2y) dx dy \\
 &= \int_0^1 [-x^2 - 2xy]_0^1 dy \\
 &= \int_0^1 (-1 - 2y) dy \\
 &= [-y - y^2]_0^1 = \boxed{-2}.
 \end{aligned}$$

23. With the given parametrization, $dx = -2 \sin t dt$ and $dy = 3 \cos t dt$, so the line integral is

$$\begin{aligned}
 \oint_C [(x-y) dx + (x+y) dy] &= \int_0^{2\pi} [(2 \cos t - 3 \sin t)(-2 \sin t) + (2 \cos t + 3 \sin t)(3 \cos t)] dt \\
 &= \int_0^{2\pi} (5 \sin t \cos t + 6 \sin^2 t + 6 \cos^2 t) dt \\
 &= \int_0^{2\pi} (5 \sin t \cos t + 6) dt \\
 &= \left[\frac{5}{2} \sin^2 t + 6t \right]_0^{2\pi} = \boxed{12\pi}.
 \end{aligned}$$

24. Since the component functions $P(x, y) = x - y$ and $Q(x, y) = x + y$ are continuous and differentiable everywhere, Green's Theorem applies, and

$$\oint_C ((x - y) dx + (x + y) dy) = \iint_R \left(\frac{\partial}{\partial x}(x + y) - \frac{\partial}{\partial y}(x - y) \right) dx dy = \iint_R 2 dx dy.$$

The region R is the ellipse $9x^2 + 4y^2 = 36$, so this integral is

$$\iint_R 2 dx dy = \int_{-2}^2 \int_{-\sqrt{36-9x^2}/2}^{\sqrt{36-9x^2}/2} 2 dy dx.$$

Since the ellipse is symmetric about the origin, we compute this area in the first quadrant and multiply by 4, so we get

$$4 \int_0^2 \int_0^{\sqrt{36-9x^2}/2} 2 dy dx = 4 \int_0^2 [2y]_0^{\sqrt{36-9x^2}/2} dx = 4 \int_0^2 \sqrt{36-9x^2} dx.$$

Use the trigonometric substitution $x = 2 \sin u$; then $dx = 2 \cos u du$. Since we are working in the first quadrant, $\sqrt{36-9x^2} = \sqrt{36-36 \sin^2 u} = 6 \cos u$. Then $x = 0$ corresponds to $u = 0$ and $x = 2$ to $u = \frac{\pi}{2}$. So we get

$$4 \int_0^2 \sqrt{36-9x^2} dx = 4 \int_0^{\pi/2} 12 \cos^2 u du = 4 \int_0^{\pi/2} (6 + 6 \cos(2u)) du = 4 [6u + 3 \sin(2u)]_0^{\pi/2} = \boxed{12\pi}.$$

25. The region is

Using Green's Theorem, the area of the region is one half the sum of the line integrals, properly oriented, of $-y dx + x dy$ along each of the boundary curves. Parametrize the outer curve, the ellipse C_1 , by

$$\mathbf{r}_1(\theta) = 2 \cos \theta \mathbf{i} + 4 \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi;$$

here we choose a counterclockwise orientation so as to keep the region on our left as we walk the curve. Similarly, we parametrize the inner circle C_2 in a clockwise parametrization so as to keep the region on our left:

$$\mathbf{r}_2(\theta) = \cos \theta \mathbf{i} + (1 - \sin \theta) \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then the area is

$$\begin{aligned} A &= \frac{1}{2} \oint_{C_1} (-y dx + x dy) + \frac{1}{2} \oint_{C_2} (-y dx + x dy) \\ &= \frac{1}{2} \int_0^{2\pi} (-4 \sin \theta \cdot (-2 \sin \theta) + 2 \cos \theta \cdot (4 \cos \theta)) d\theta \\ &\quad + \frac{1}{2} \int_0^{2\pi} ((\sin \theta - 1) \cdot (-\sin \theta) + \cos \theta \cdot (-\cos \theta)) d\theta \\ &= \frac{1}{2} \int_0^{2\pi} 8 d\theta + \frac{1}{2} \int_0^{2\pi} (-1 + \sin \theta) d\theta \\ &= 8\pi + \frac{1}{2} [-\theta - \cos \theta]_0^{2\pi} = \boxed{7\pi}. \end{aligned}$$

26. (a) When $u = 0$, the equation is $\mathbf{r}(0, v) = \mathbf{0}$, so the coordinate curve consists of only the origin. Otherwise, for $0 < u \leq 1$, the coordinate curve is an ellipse whose semimajor axis is $3u$ and whose semiminor axis is $2u$, lying in the plane $z = u^2$. When $v = 0$, the coordinate curve is $\mathbf{r}(u, 0) = 3u \mathbf{i} + u^2 \mathbf{k}$, which is a parabolic arc since $z = u^2 = \frac{1}{9}(3u \cos 0)^2 = \frac{1}{9}x^2$. When $v = \frac{\pi}{2}$, the coordinate curve is $\mathbf{r}(u, \frac{\pi}{2}) = 2u \mathbf{j} + u^2 \mathbf{k}$, which is again a parabolic arc. In general, the coordinate curves are all parabolic arcs.

- (b) We have $x = 3u \cos v$, $y = 2u \sin v$, $z = u^2$. Then

$$\left(\frac{1}{3}x\right)^2 + \left(\frac{1}{2}y\right)^2 = (u \cos v)^2 + (u \sin v)^2 = u^2 = z.$$

Expanding gives

$$z = \frac{x^2}{9} + \frac{y^2}{4},$$

which is a paraboloid.

27. The region is

The level curve for any value of z is the ellipse $4x^2 + 25y^2 = 100$, which is parametrized in polar coordinates by $x = 5 \cos \theta$, $y = 2 \sin \theta$ for $0 \leq \theta \leq 2\pi$. Then using cylindrical coordinates, $z = z$, and we get for the desired parametrization

$$\mathbf{r}(\theta, z) = 5 \cos \theta \mathbf{i} + 2 \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 1 \leq z \leq 6.$$

28. (a) The values of u and v that give the point $(\sqrt{3}, 4, 1)$ are found by solving the three equations

$$\begin{aligned}u \sin v &= \sqrt{3}, \\u^2 &= 4, \\u \cos v &= 1.\end{aligned}$$

So $u = \pm 2$. If $u = 2$, then $v = \frac{\pi}{3}$; if $u = -2$, then $v = \frac{2\pi}{3}$. We consider only the values $u = 2$, $v = \frac{\pi}{3}$ (choosing the other pair would give the same answer). Next, find the partial derivatives of $\mathbf{r}$:

$$\begin{aligned}\mathbf{r}_u(u, v) &= \sin v \mathbf{i} + 2u \mathbf{j} + \cos v \mathbf{k} \\ \mathbf{r}_v(u, v) &= u \cos v \mathbf{i} - u \sin v \mathbf{k}.\end{aligned}$$

When $u = 2$ and $v = \frac{\pi}{3}$, these are

$$\begin{aligned}\mathbf{r}_u\left(2, \frac{\pi}{3}\right) &= \sin \frac{\pi}{3} \mathbf{i} + 4 \mathbf{j} + \cos \frac{\pi}{3} \mathbf{k} = \frac{\sqrt{3}}{2} \mathbf{i} + 4 \mathbf{j} + \frac{1}{2} \mathbf{k} \\ \mathbf{r}_v\left(2, \frac{\pi}{3}\right) &= 2 \cos \frac{\pi}{3} \mathbf{i} - 2 \sin \frac{\pi}{3} \mathbf{k} = \mathbf{i} - \sqrt{3} \mathbf{k}.\end{aligned}$$

Therefore a normal vector to the surface at the given point is

$$\left\langle \frac{\sqrt{3}}{2}, 4, \frac{1}{2} \right\rangle \times \langle 1, 0, -\sqrt{3} \rangle = \langle -4\sqrt{3}, 2, -4 \rangle.$$

So the equation of the tangent plane at $(\sqrt{3}, 4, 1)$ is $-4\sqrt{3}(x - \sqrt{3}) + 2(y - 4) - 4(z - 1) = 0$, or $\boxed{2\sqrt{3}x - y + 2z = 4}$.

- (b) The normal line has direction vector $\langle -4\sqrt{3}, 2, -4 \rangle$, so it can be parametrized as

$$\boxed{(\sqrt{3} - 4\sqrt{3}t) \mathbf{i} + (4 + 2t) \mathbf{j} + (1 - 4t) \mathbf{k}}.$$

29. With the given parametrization, we have

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \sin v & 2u & \cos v \\ u \cos v & 0 & -u \sin v \end{vmatrix} = -2u^2 \sin v \mathbf{i} + u \mathbf{j} - 2u^2 \cos v \mathbf{k}.$$

Then

$$\|\mathbf{r}_u \times \mathbf{r}_v\| = \sqrt{4u^4 + u^2} = u\sqrt{4u^2 + 1}.$$

Therefore the surface area is

$$\iint_S \|\mathbf{r}_u \times \mathbf{r}_v\| dS = \int_0^4 \int_0^{2\pi} u\sqrt{4u^2 + 1} dv du = 2\pi \int_0^4 u\sqrt{4u^2 + 1} du.$$

Now use the substitution $t = 4u^2 + 1$, so that $dt = 8u du$; then $u = 0$ corresponds to $t = 1$, and $u = 4$ to $t = 65$, so we get

$$2\pi \int_0^4 u\sqrt{4u^2 + 1} du = 2\pi \int_1^{65} \frac{1}{8} t^{1/2} dt = 2\pi \left[\frac{1}{12} t^{3/2} \right]_1^{65} = \boxed{\frac{65\sqrt{65}}{6} \pi - \frac{\pi}{6}}.$$

30. With the given parametrization, we have

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 3 \cos u \sin v & -3 \sin u \sin v \\ -\sin v & 3 \sin u \cos v & 3 \cos u \cos v \end{vmatrix} = 9 \cos v \sin v \mathbf{i} + 3 \sin u \sin^2 v \mathbf{j} + 3 \cos u \sin^2 v \mathbf{k}.$$

Then

$$\begin{aligned}\|\mathbf{r}_u \times \mathbf{r}_v\| &= \sqrt{81 \cos^2 v \sin^2 v + 9 \sin^2 u \sin^4 v + 9 \cos^2 u \sin^4 v} \\ &= \sqrt{81 \cos^2 v \sin^2 v + 9 \sin^4 v} = 3 \sin v \sqrt{9 \cos^2 v + \sin^2 v} = 3 \sin v \sqrt{8 \cos^2 v + 1}.\end{aligned}$$

Therefore the integral is

$$\begin{aligned}\iint_S x \|\mathbf{r}_u \times \mathbf{r}_v\| dS &= \int_0^{\pi/2} \int_0^{2\pi} 3 \sin v \cos v \sqrt{8 \cos^2 v + 1} du dv \\ &= 2\pi \int_0^{\pi/2} 3 \sin v \cos v \sqrt{8 \cos^2 v + 1} dv.\end{aligned}$$

Now use the substitution $t = 8 \cos^2 v + 1$, so that $dt = -16 \sin v \cos v dv$; then $v = 0$ corresponds to $t = 9$ and $v = \frac{\pi}{2}$ to $t = 1$, so we get

$$2\pi \int_0^{\pi/2} 3 \sin v \cos v \sqrt{8 \cos^2 v + 1} dv = 2\pi \int_9^1 \left(-\frac{3}{16} t^{1/2} dt \right) = -\frac{3}{8} \pi \left[\frac{2}{3} t^{3/2} \right]_9^1 = \frac{1}{4} \pi (27 - 1) = \boxed{\frac{13}{2} \pi}.$$

31. Parametrize the sphere using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = 2 \cos \theta \sin \phi \mathbf{i} + 2 \sin \theta \sin \phi \mathbf{j} + 2 \cos \phi \mathbf{k};$$

then we have

$$\begin{aligned}\mathbf{r}_\theta \times \mathbf{r}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 \sin \theta \sin \phi & 2 \cos \theta \sin \phi & 0 \\ 2 \cos \theta \cos \phi & 2 \sin \theta \cos \phi & -2 \sin \phi \end{vmatrix} \\ &= -4 \cos \theta \sin^2 \phi \mathbf{i} - 4 \sin \theta \sin^2 \phi \mathbf{j} - 4 \sin \phi \cos \phi \mathbf{k} \\ \|\mathbf{r}_\theta \times \mathbf{r}_\phi\| &= \sqrt{16 \cos^2 \theta \sin^4 \phi + 16 \sin^2 \theta \sin^4 \phi + 16 \sin^2 \phi \cos^2 \phi} \\ &= \sqrt{16 \sin^4 \phi + 16 \sin^2 \phi \cos^2 \phi} \\ &= 4 \sin \phi \sqrt{\sin^2 \phi + \cos^2 \phi} = 4 \sin \phi.\end{aligned}$$

Then the integral is

$$\iint_S z^2 dS = \int_0^{2\pi} \int_0^\pi 4 \cos^2 \phi \cdot 4 \sin \phi d\phi d\theta = 16 \int_0^{2\pi} \left[-\frac{1}{3} \cos^3 \phi \right]_0^\pi d\theta = 16 \int_0^{2\pi} \frac{2}{3} d\theta = \boxed{\frac{64\pi}{3}}.$$

32. The solid is

The top surface is parametrized using spherical coordinates:

$$\mathbf{r}(\theta, \phi) = 5 \cos \theta \sin \phi \mathbf{i} + 5 \sin \theta \sin \phi \mathbf{j} + 5 \cos \phi \mathbf{k};$$

then

$$\begin{aligned} \mathbf{r}_\theta &= -5 \sin \theta \sin \phi \mathbf{i} + 5 \cos \theta \sin \phi \mathbf{j}, & \mathbf{r}_\phi &= 5 \cos \theta \cos \phi \mathbf{i} + 5 \sin \theta \cos \phi \mathbf{j} - 5 \sin \phi \mathbf{k} \\ \mathbf{r}_\theta \times \mathbf{r}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -5 \sin \theta \sin \phi & 5 \cos \theta \sin \phi & 0 \\ 5 \cos \theta \cos \phi & 5 \sin \theta \cos \phi & -5 \sin \phi \end{vmatrix} = -25 \cos \theta \sin^2 \phi \mathbf{i} - 25 \sin \theta \sin^2 \phi \mathbf{j} - 25 \sin \phi \cos \phi \mathbf{k}. \end{aligned}$$

At the point $(1, 0, 0)$, corresponding to $\theta = 0$ and $\phi = \frac{\pi}{2}$, this gives $-25 \mathbf{i}$, which is inward-pointing. So the outward-pointing normals are the negative of the above, or

$$25 \cos \theta \sin^2 \phi \mathbf{i} + 25 \sin \theta \sin^2 \phi \mathbf{j} + 25 \sin \phi \cos \phi \mathbf{k}.$$

The magnitude of this vector is

$$\begin{aligned} \sqrt{25^2 \cos^2 \theta \sin^4 \phi + 25^2 \sin^2 \theta \sin^4 \phi + 25^2 \sin^2 \phi \cos^2 \phi} &= \sqrt{25^2 \sin^4 \phi + 25^2 \sin^2 \phi \cos^2 \phi} \\ &= 25 \sin \phi \sqrt{\sin^2 \phi + \cos^2 \phi} = 25 \sin \phi, \end{aligned}$$

so that the unit normal is

$$\cos \theta \sin \phi \mathbf{i} + \sin \theta \sin \phi \mathbf{j} + \cos \phi \mathbf{k}.$$

Along the bottom edge we have the plane $z = 0$; clearly an outward unit normal to this plane is $-\mathbf{k}$.

33. Parametrize the surface using cylindrical coordinates:

$$\mathbf{r}(\theta, z) = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad -1 \leq z \leq 1.$$

Then

$$\mathbf{r}_\theta \times \mathbf{r}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3 \sin \theta & 3 \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = 3 \cos \theta \mathbf{i} + 3 \sin \theta \mathbf{j}.$$

Therefore $\|\mathbf{r}_\theta \times \mathbf{r}_z\| = 3$, and the integral is

$$\iint_S x \, dS = \int_{-1}^1 \int_0^{2\pi} 3 \cdot 3 \cos \theta \, d\theta \, dz = \int_{-1}^1 [9 \sin \theta]_0^{2\pi} \, dz = \int_{-1}^1 0 \, dz = \boxed{0}.$$

34. The surface in question is the plane

For any values of x and y such that $x^2 + y^2 \leq 9$, the corresponding point on the plane is $z = 9 - x - y$. So we can parametrize the surface using cylindrical coordinates:

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + (9 - r \cos \theta - r \sin \theta) \mathbf{k}, \quad 0 \leq r \leq 3, \quad 0 \leq \theta \leq 2\pi.$$

Then

$$\mathbf{r}_r \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & -\cos \theta - \sin \theta \\ -r \sin \theta & r \cos \theta & r \sin \theta - r \cos \theta \end{vmatrix} = r \mathbf{i} + r \mathbf{j} + r \mathbf{k},$$

so that $\|\mathbf{r}_r \times \mathbf{r}_\theta\| = r\sqrt{3}$. Then the integral is

$$\begin{aligned} \iint_S z \, dS &= \int_0^3 \int_0^{2\pi} (9 - r \cos \theta - r \sin \theta) \cdot r\sqrt{3} \, d\theta \, dr \\ &= \sqrt{3} \int_0^3 \int_0^{2\pi} (9r - r^2 \cos \theta - r^2 \sin \theta) \, d\theta \, dr \\ &= \sqrt{3} \int_0^3 [9r\theta - r^2 \sin \theta + r^2 \cos \theta]_0^{2\pi} \, dr \\ &= \sqrt{3} \int_0^3 18\pi r \, dr \\ &= \sqrt{3} [9\pi r^2]_0^3 = \boxed{81\pi\sqrt{3}}. \end{aligned}$$

35. We can parametrize this plane by $y = t$, $z = u$, $x = t + u$ for $0 \leq t \leq \pi$ and $0 \leq u \leq \pi - t$. Then

$$\mathbf{r}(t, u) = (t + u) \mathbf{i} + t \mathbf{j} + u \mathbf{k},$$

so that

$$\mathbf{r}_t \times \mathbf{r}_u = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 0 \\ 1 & 0 & 1 \end{vmatrix} = \mathbf{i} - \mathbf{j} - \mathbf{k}.$$

Then $\|\mathbf{r}_t \times \mathbf{r}_u\| = \sqrt{3}$, so the integral is

$$\begin{aligned} \iint_S \cos x \, dS &= \int_0^\pi \int_0^{\pi-t} \cos(t + u) \cdot \sqrt{3} \, du \, dt \\ &= \sqrt{3} \int_0^\pi [\sin(t + u)]_0^{\pi-t} \, dt = \sqrt{3} \int_0^\pi (\sin \pi - \sin t) \, dt. \end{aligned}$$

But $\sin \pi = 0$, so this integral becomes

$$\sqrt{3} \int_0^\pi (-\sin t) \, dt = \sqrt{3} [\cos t]_0^\pi = \boxed{-2\sqrt{3}}.$$

36. Parametrize this cylinder using cylindrical coordinates:

$$\mathbf{r}(\theta, z) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + z \mathbf{k}, \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq z \leq 1.$$

Differentiating gives

$$\mathbf{r}_\theta = -\sin \theta \mathbf{i} + \cos \theta \mathbf{j}, \quad \mathbf{r}_z = \mathbf{k}.$$

Therefore

$$\mathbf{r}_\theta \times \mathbf{r}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}.$$

This normal points outwards, so we use this one rather than its negative. The vector field is

$$\mathbf{F} = x^2 \mathbf{i} + y \mathbf{j} - z \mathbf{k} = \cos^2 \theta \mathbf{i} + \sin \theta \mathbf{j} - z \mathbf{k}.$$

It follows that the flux is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^{2\pi} \int_0^1 (\cos^2 \theta \mathbf{i} + \sin \theta \mathbf{j} - z \mathbf{k}) \cdot (\cos \theta \mathbf{i} + \sin \theta \mathbf{j}) \, dz \, d\theta \\ &= \int_0^{2\pi} \int_0^1 (\cos^3 \theta + \sin^2 \theta) \, dz \, d\theta \\ &= \int_0^{2\pi} \left(\cos \theta (1 - \sin^2 \theta) + \frac{1}{2} - \frac{1}{2} \cos(2\theta) \right) d\theta \\ &= \left[\sin \theta - \frac{1}{3} \sin^3 \theta + \frac{1}{2} \theta - \frac{1}{4} \sin(2\theta) \right]_0^{2\pi} = \boxed{\pi}. \end{aligned}$$

37. (a) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(z \cos x) + \frac{\partial}{\partial y}(\sin y) + \frac{\partial}{\partial z}(e^x) = \boxed{\cos y - z \sin x}.$

(b) $\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z \cos x & \sin y & e^x \end{vmatrix} = \boxed{(\cos x - e^x) \mathbf{j}}.$

(c) Parametrize the surface of the paraboloid using cylindrical coordinates:

$$\mathbf{r}(r, \theta) = r \cos \theta \mathbf{i} + r \sin \theta \mathbf{j} + r^2 \mathbf{k}.$$

Then

$$\begin{aligned} \mathbf{r}_r &= \cos \theta \mathbf{i} + \sin \theta \mathbf{j} + 2r \mathbf{k}, & \mathbf{r}_\theta &= -r \sin \theta \mathbf{i} + r \cos \theta \mathbf{j} \\ \mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 2r \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} = -2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k} \\ \|\mathbf{r}_r \times \mathbf{r}_\theta\| &= \sqrt{4r^4 + r^2}. \end{aligned}$$

Therefore

$$\begin{aligned} \iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^1 \int_0^{2\pi} (\cos x - e^x) \mathbf{j} \cdot \frac{1}{\sqrt{4r^4 + r^2}} (-2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \\ &\quad \cdot \sqrt{4r^4 + r^2} \, d\theta \, dr \\ &= \int_0^1 \int_0^{2\pi} (-2r^2 (\cos(r \cos \theta) - e^{r \cos \theta}) \sin \theta) \, d\theta \, dr. \end{aligned}$$

Now make the substitution $t = \cos \theta$; then $dt = -\sin \theta \, d\theta$; $\theta = 0$ corresponds to $t = 1$, as does $\theta = 2\pi$, so we get

$$\int_0^1 \int_1^1 (2r^2 (\cos(rt) - e^{rt})) \, dt = 0$$

since the upper and lower limits of the inner integral are the same. For the other half of Stokes' Theorem, parametrize the unit circle clockwise, via

$$\mathbf{r}(t) = \cos t \mathbf{i} - \sin t \mathbf{j} + \mathbf{k}, 0 \leq t \leq 2\pi,$$

since we want to keep the surface on our left as we walk the circle. Then

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\cos(\cos t) \mathbf{i} - \sin(\sin t) \mathbf{j} + e^{\cos t} \mathbf{k}) \cdot (-\sin t \mathbf{i} - \cos t \mathbf{j}) \, dt \\ &= \int_0^{2\pi} (-\cos(\cos t) \sin t + \sin(\sin t) \cos t) \, dt \\ &= [\sin(\cos t) - \cos(\sin t)]_0^{2\pi} = \boxed{0}. \end{aligned}$$

38. (a) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(-3y) + \frac{\partial}{\partial z}(4z^2) = \boxed{2x + 8z - 3}.$

(b) $\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x^2 & -3y & 4z^2 \end{vmatrix} = \boxed{\mathbf{0}}.$

(c) Since $\operatorname{curl} \mathbf{F} = \mathbf{0}$, we have

$$\iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS = 0.$$

For the other half of Stokes' Theorem, parametrize the unit circle as in Problem 37. Then

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (x^2 \mathbf{i} - 3y \mathbf{j} + 4z^2 \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) \, d\theta \\ &= \int_0^{2\pi} (\cos^2 \theta \mathbf{i} - 3 \sin^2 \theta \mathbf{j} + 4 \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) \, d\theta \\ &= \int_0^{2\pi} (-\sin \theta \cos^2 \theta - 3 \sin^3 \theta \cos \theta) \, d\theta \\ &= \left[\frac{1}{3} \cos^3 \theta - \sin^3 \theta \right]_0^{2\pi} = \boxed{0}. \end{aligned}$$

39. (a) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = \boxed{3}.$

(b) $\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x & y & z \end{vmatrix} = \boxed{\mathbf{0}}.$

(c) Since $\operatorname{curl} \mathbf{F} = \mathbf{0}$, we have

$$\iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS = 0.$$

For the other half of Stokes' Theorem, parametrize the unit circle as in Problem 37. Then

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (x \mathbf{i} + y \mathbf{j} + z \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) \, d\theta \\ &= \int_0^{2\pi} (\cos \theta \mathbf{i} + \sin \theta \mathbf{j} + 1 \mathbf{k}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) \, d\theta \\ &= \int_0^{2\pi} (-\sin \theta \cos \theta + \sin \theta \cos \theta) \, d\theta = \boxed{0}. \end{aligned}$$

40. (a) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(xe^y) + \frac{\partial}{\partial y}(-ye^z) + \frac{\partial}{\partial z}(ze^x) = \boxed{e^y - e^z + e^x}.$

(b) $\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xe^y & -ye^z & ze^x \end{vmatrix} = \boxed{ye^z \mathbf{i} - ze^x \mathbf{j} - xe^y \mathbf{k}}.$

(c) Parametrize the surface of the paraboloid as in Exercise 37. Then

$$\begin{aligned} \iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} \, dS &= \int_0^1 \int_0^{2\pi} (ye^z \mathbf{i} - ze^x \mathbf{j} - xe^y \mathbf{k}) \cdot \frac{1}{\sqrt{4r^4 + r^2}} (-2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \\ &\quad \cdot \sqrt{4r^4 + r^2} \, d\theta \, dr \\ &= \int_0^1 \int_0^{2\pi} (r \sin \theta e^{r^2} \mathbf{i} - r^2 e^{r \cos \theta} \mathbf{j} - r \cos \theta e^{r \sin \theta} \mathbf{k}) \\ &\quad \cdot (-2r^2 \cos \theta \mathbf{i} - 2r^2 \sin \theta \mathbf{j} + r \mathbf{k}) \, d\theta \, dr \\ &= \int_0^1 \int_0^{2\pi} (-2r^3 \sin \theta \cos \theta + 2r^4 \sin \theta e^{r \cos \theta} - r^2 \cos \theta e^{r \sin \theta}) \, d\theta \, dr. \end{aligned}$$

For the second term, use the substitution $t = \cos \theta$; $dt = -\sin \theta d\theta$; $\theta = 0$ corresponds to $t = 1$, as does $\theta = 2\pi$. Since the upper and lower bounds of the t -integration will be the same, the integral of this term will be zero. Similarly, for the third term, use the substitution $t = \sin \theta$; $dt = \cos \theta d\theta$, and here $\theta = 0$ corresponds to $t = 0$ as does $\theta = 2\pi$. Since the upper and lower bounds of the t -integration will be the same, the integral of this term will be zero as well. We are left with

$$\int_0^1 \int_0^{2\pi} (-2r^3 \sin \theta \cos \theta) d\theta dr = \int_0^1 [-r^3 \sin^2 \theta]_0^{2\pi} = 0.$$

So the surface integral is zero. For the other half of Stokes' Theorem, parametrize the unit circle clockwise as in Problem 37. Then, via

$$\mathbf{r}(t) = \cos t \mathbf{i} - \sin t \mathbf{j} + \mathbf{k}, 0 \leq t \leq 2\pi,$$

since we want to keep the surface on our left as we walk the circle. Then

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\cos t e^{-\sin t} \mathbf{i} + e \sin t \mathbf{j} + e^{\cos t} \mathbf{k}) \cdot (-\sin t \mathbf{i} - \cos t \mathbf{j}) dt \\ &= \int_0^{2\pi} (-\sin t \cos t e^{-\sin t} - e \sin t \cos t) dt \\ &= \int_0^{2\pi} (-\sin t \cos t e^{-\sin t}) dt - \int_0^{2\pi} e \sin t \cos t dt \\ &= \int_0^{2\pi} (-\sin t \cos t e^{-\sin t}) dt - \left[\frac{1}{2} e \sin^2 t \right]_0^{2\pi} \\ &= \int_0^{2\pi} (-\sin t \cos t e^{-\sin t}) dt. \end{aligned}$$

To evaluate the remaining integral, use integration by parts with $u = -\sin t$, $dv = \cos t e^{-\sin t} dt$. We can integrate dv with respect to t easily since $\frac{d}{dt}(-\sin t) = -\cos t$, to get $v = -e^{-\sin t}$. Also $du = -\cos t dt$, so the integral is

$$\int_0^{2\pi} (-\sin t \cos t e^{-\sin t}) dt = [\sin t e^{-\sin t}]_0^{2\pi} - \int_0^{2\pi} \cos t e^{-\sin t} dt = - \int_0^{2\pi} \cos t e^{-\sin t} dt.$$

As above, this is easily integrable since $\frac{d}{dt}(-\sin t) = -\cos t$, and we get finally

$$- \int_0^{2\pi} \cos t e^{-\sin t} dt = -[-e^{-\sin t}]_0^{2\pi} = \boxed{0}.$$

41. The given surface bounds the solid cylinder of radius 1 extending from $z = 0$ to $z = 1$, and the given vector field is differentiable everywhere, so the Divergence Theorem applies, and

$$\operatorname{div} \mathbf{F} = 2x + 1 - 1 = 2x.$$

To integrate, convert to cylindrical coordinates; then

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV = \int_0^1 \int_0^1 \int_0^{2\pi} 2r \cos \theta \cdot r d\theta dr dz = \int_0^1 \int_0^1 [2r^2 \sin \theta]_0^{2\pi} dr dz = \boxed{0}.$$

42. (a) If $\nabla f = (yz - y - z)\mathbf{i} + (xz - x - z)\mathbf{j} + (xy - x - y)\mathbf{k}$, then $\frac{\partial f}{\partial x} = yz - y - z$. Integrating both sides with respect to x gives

$$f(x, y, z) = xyz - xy - xz + h(y, z).$$

Now differentiate with respect to y and set the result equal to the y -component:

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}(xyz - xy - xz + h(y, z)) = xz - x + h_y = xz - x - z.$$

Therefore $h_y = -z$, so that $h(y, z) = -yz + k(z)$, and then

$$f(x, y, z) = xyz - xy - xz - yz + k(z).$$

Now differentiate with respect to z and set the result equal to the z -component:

$$\frac{\partial f}{\partial z} = \frac{\partial}{\partial z}(xyz - xy - xz - yz + k(z)) = xy - x - y + k'(z) = xy - x - y.$$

Therefore $k'(z) = 0$, so that $k(z) = C$ for C an arbitrary constant. Choosing $C = 0$, we get

$$f(x, y, z) = \boxed{xyz - xy - xz - yz}.$$

- (b) Since the given vector field is a gradient, it is conservative. So by the Fundamental Theorem of Line Integrals, since C is a path from $(0, 0, 0)$ to $(1, 1, 1)$, we have

$$\int_C [(yz - y - z) dx + (xz - x - z) dy + (xy - x - y) dz] = f(1, 1, 1) - f(0, 0, 0) = \boxed{-2},$$

which agrees with the result from Problem 7.

43. Let $P(x, y, z) = xz$, $Q(x, y, z) = yz$, $R(x, y, z) = x^2$. Then from the second form of the Divergence Theorem in Section 15.8,

$$\iint_S (xz \cos \alpha + yz \cos \beta + x^2 \cos \gamma) dS = \iiint_E \left(\frac{\partial}{\partial x}(xz) + \frac{\partial}{\partial y}(yz) + \frac{\partial}{\partial z}(x^2) \right) dV = \iiint_E 2z dV,$$

where E is the interior of the upper hemisphere of the unit sphere. Convert to spherical coordinates to evaluate the integral:

$$\begin{aligned} \iiint_E 2z dV &= \int_0^1 \int_0^{2\pi} \int_0^{\pi/2} 2\rho \cos \phi \cdot \rho^2 \sin \phi d\phi d\theta d\rho \\ &= \int_0^1 \int_0^{2\pi} \int_0^{\pi/2} 2\rho^3 \sin \phi \cos \phi d\phi d\theta d\rho \\ &= \int_0^1 \int_0^{2\pi} [\rho^3 \sin^2 \phi]_0^{\pi/2} d\theta d\rho \\ &= \int_0^1 \int_0^{2\pi} \rho^3 d\theta d\rho \\ &= \int_0^1 2\pi \rho^3 d\rho \\ &= \left[\frac{1}{2} \pi \rho^4 \right]_0^1 = \boxed{\frac{\pi}{2}}. \end{aligned}$$

44. Write $\mathbf{r}(x, y, z) = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$; then

$$\begin{aligned} \operatorname{div} \|\mathbf{r}\|^2 \mathbf{r} &= \operatorname{div} (x(x^2 + y^2 + z^2)\mathbf{i} + y(x^2 + y^2 + z^2)\mathbf{j} + z(x^2 + y^2 + z^2)\mathbf{k}) \\ &= (x^2 + y^2 + z^2) + x(2x) + (x^2 + y^2 + z^2) + y(2y) + (x^2 + y^2 + z^2) + z(2z) \\ &= 5(x^2 + y^2 + z^2). \end{aligned}$$

Perform the integration using spherical coordinates:

$$\begin{aligned}
 \iiint_E \operatorname{div} \mathbf{F} \, dV &= \int_0^1 \int_0^{2\pi} \int_0^\pi 5\rho^2 \cdot \rho^2 \sin \phi \, d\phi \, d\theta \, d\rho \\
 &= \int_0^1 \int_0^{2\pi} [-5\rho^4 \cos \phi]_0^\pi \, d\theta \, d\rho \\
 &= \int_0^1 \int_0^{2\pi} 10\rho^4 \, d\theta \, d\rho \\
 &= \int_0^1 20\pi\rho^4 \, d\rho \\
 &= [4\pi\rho^5]_0^1 = \boxed{4\pi}.
 \end{aligned}$$

45. The curve is the boundary of the plane

Since all three components of the vector field are everywhere differentiable, Stokes' Theorem applies. We parametrize the triangle by

$$\mathbf{r}(x, y) = x\mathbf{i} + y\mathbf{j} + (1 - x - y)\mathbf{k}, \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1 - x.$$

Then

$$\mathbf{r}_x \times \mathbf{r}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -1 \\ 0 & 1 & -1 \end{vmatrix} = \mathbf{i} + \mathbf{j} + \mathbf{k}.$$

Since this is upward-pointing, we use this normal, since it is consistent with a counterclockwise orientation of the boundary. Next,

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x - y & y - z & z - x \end{vmatrix} = \mathbf{i} + \mathbf{j} + \mathbf{k}.$$

Then

$$\begin{aligned}
 \oint_C [(x-y) dx + (y-z) dy + (z-x) dz] &= \iint_S \operatorname{curl} \mathbf{F} \cdot \mathbf{n} dS \\
 &= \int_0^1 \int_0^{1-x} (\mathbf{i} + \mathbf{j} + \mathbf{k}) \cdot (\mathbf{i} + \mathbf{j} + \mathbf{k}) dy dx \\
 &= \int_0^1 \int_0^{1-x} 3 dy dx \\
 &= \int_0^1 [3y]_0^{1-x} dx \\
 &= \int_0^1 3(1-x) dx \\
 &= \left[-\frac{3}{2}(1-x)^2 \right]_0^1 = \boxed{\frac{3}{2}}.
 \end{aligned}$$

46. (a) Since the three component functions are differentiable everywhere, the Divergence Theorem applies, so that the flux is

$$\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_E \operatorname{div} \mathbf{F} dV.$$

Here E is the interior of the unit sphere, and

$$\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^3) + \frac{\partial}{\partial y}(y^3) + \frac{\partial}{\partial z}(z^3) = 3(x^2 + y^2 + z^2).$$

So the flux is

$$\iiint_E 3(x^2 + y^2 + z^2) dV.$$

Convert to spherical coordinates, giving

$$\begin{aligned}
 \int_0^1 \int_0^{2\pi} \int_0^\pi 3\rho^2 \cdot \rho^2 \sin \phi d\phi d\theta d\rho &= \int_0^1 \int_0^{2\pi} [-3\rho^4 \cos \phi]_0^\pi d\theta d\rho \\
 &= \int_0^1 \int_0^{2\pi} 6\rho^4 d\theta d\rho \\
 &= \int_0^1 12\pi\rho^4 d\rho \\
 &= \left[\frac{12}{5}\pi\rho^5 \right]_0^1 = \boxed{\frac{12}{5}\pi}.
 \end{aligned}$$

- (b) To determine the circulation, we must parametrize the unit circle in the xy -plane:

$$\mathbf{r}(\theta) = \cos \theta \mathbf{i} + \sin \theta \mathbf{j}, \quad 0 \leq \theta \leq 2\pi.$$

Then the circulation is

$$\begin{aligned}
 \oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} (\cos^3 \theta \mathbf{i} + \sin^3 \theta \mathbf{j}) \cdot (-\sin \theta \mathbf{i} + \cos \theta \mathbf{j}) d\theta \\
 &= \int_0^{2\pi} (-\sin \theta \cos^3 \theta + \cos \theta \sin^3 \theta) d\theta \\
 &= \left[\frac{1}{4} \cos^4 \theta + \frac{1}{4} \sin^4 \theta \right]_0^{2\pi} = \boxed{0}.
 \end{aligned}$$

47. Computing $\text{curl } \mathbf{F}$ gives

$$\begin{aligned}\text{curl } \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ yz & xy & xy \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(xy) - \frac{\partial}{\partial z}(xy) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(yz) - \frac{\partial}{\partial x}(xy) \right) \mathbf{j} + \left(\frac{\partial}{\partial x}(xy) - \frac{\partial}{\partial y}(yz) \right) \mathbf{k} \\ &= (x - 0) \mathbf{i} + (y - y) \mathbf{j} + (y - z) \mathbf{k} = x \mathbf{i} + (y - z) \mathbf{k} \neq \mathbf{0}.\end{aligned}$$

Since $\text{curl } \mathbf{F} \neq \mathbf{0}$, $\mathbf{F}$ is not conservative (see Objective 4 in Section 15.9).

48. Computing $\text{curl } \mathbf{F}$ gives

$$\begin{aligned}\text{curl } \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 2xy^2z & 2x^2yz & x^2y^2 - 2z \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(x^2y^2 - 2z) - \frac{\partial}{\partial z}(2x^2yz) \right) \mathbf{i} + \left(\frac{\partial}{\partial z}(2xy^2z) - \frac{\partial}{\partial x}(x^2y^2 - 2z) \right) \mathbf{j} \\ &\quad + \left(\frac{\partial}{\partial x}(2x^2yz) - \frac{\partial}{\partial y}(2xy^2z) \right) \mathbf{k} \\ &= (2x^2y - 2x^2y) \mathbf{i} + (2xy^2 - 2xy^2) \mathbf{j} + (4xyz - 4xyz) \mathbf{k} = \mathbf{0}.\end{aligned}$$

Since $\text{curl } \mathbf{F} = \mathbf{0}$, $\mathbf{F}$ is conservative (see Objective 4 in Section 15.9).

Differential Equations

16.1 Classification of Ordinary Differential Equations

Concepts and Vocabulary

1. The differential equation $\frac{d^2y}{dx^2} + 5\left(\frac{dy}{dx}\right)^3 - y = 0$ is of order two and degree 1. It is second-order because the highest-order derivative is the second derivative, and it is degree 1 because the exponent of the second derivative is 1.
2. True. The differential equation $(x^2 + 2)\frac{dy}{dx} - \frac{1}{x}y = 0$ is linear. Since $P_0(x) = x^2 + 2$ and $P_1(x) = \frac{1}{x}$ are both functions of x alone and no term contains more than one derivative, the differential equation is linear.
3. True. $y = -4x^2 + 100$ is a solution of the differential equation $\frac{dy}{dx} = -8x$.
4. False. $y = 8e^{5x}$ is not a solution of the differential equation $\frac{dy}{dx} + 3 = 8e^{5x}$. The derivative of y is $\frac{dy}{dx} = 40e^{5x}$.

Skill Building

5. The differential equation $\frac{dy}{dx} + x^2y = xe^x$ is first-order because the highest-order derivative is the first derivative. It has degree 1 because the exponent of the first derivative is 1. Since $P_0(x) = 1$, $P_1(x) = x^2$, and $Q(x) = xe^x$ are all functions of x alone and no term contains more than one derivative, the differential equation is linear.
6. The differential equation $\frac{d^3y}{dx^3} + 4\frac{d^2y}{dx^2} - 5\frac{dy}{dx} + 3y = \sin x$ is third-order because the highest-order derivative is the third derivative. It has degree 1 because the exponent of the third derivative is 1. Since $P_0(x) = 1$, $P_1(x) = 4$, $P_2(x) = -5$, $P_3(x) = 3$, and $Q(x) = \sin x$ are all functions of x alone and no term contains more than one derivative, the differential equation is linear.
7. The differential equation $\frac{d^4y}{dx^4} + 3\frac{d^2y}{dx^2} + 5y = 0$ is fourth-order because the highest-order derivative is the fourth derivative. It has degree 1 because the exponent of the fourth derivative is 1. Since $P_0(x) = 1$, $P_1(x) = 0$, $P_2(x) = 3$, $P_3(x) = 0$, and $P_4(x) = 5$ are all functions of x alone and no term contains more than one derivative, the differential equation is linear.
8. The differential equation $\frac{d^2y}{dx^2} + y \sin x = 0$ is second-order because the highest-order derivative is the second derivative. It has degree 1 because the exponent of the second derivative is 1. Since $P_0(x) = 1$, $P_1(x) = 0$, and $P_2(x) = \sin x$ are all functions of x alone and no term contains more than one derivative, the differential equation is linear.

9. The differential equation $\frac{d^2y}{dx^2} + x \sin y = 0$ is second-order because the highest-order derivative is the second derivative. It has degree 1 because the exponent of the second derivative is 1. Since $\sin y$ is not a polynomial expression of y , the differential equation is nonlinear.
10. The differential equation $\frac{d^6x}{dt^6} + \frac{d^4x}{dt^4} + \frac{d^3x}{dt^3} + x = t$ is sixth-order because the highest-order derivative is the sixth derivative. It has degree 1 because the exponent of the first derivative is 1. Since $P_0(t) = P_2(t) = P_3(t) = P_6(t) = 1$, $P_1(t) = P_4(t) = P_5(t) = 0$, and $Q(t) = t$ are all functions of t alone and no term contains more than one derivative, the differential equation is linear.
11. The differential equation $\left(\frac{dr}{ds}\right)^2 = \left(\frac{d^2r}{ds^2}\right)^3 + 1$ is second-order because the highest-order derivative is the second derivative. It has degree 3 because the exponent of the first derivative is 3. Since the first (or second) derivative is not of degree 1, the differential equation is nonlinear.
12. The differential equation $x(y'')^3 + (y')^4 - y = 0$ is second-order because the highest-order derivative is the second derivative. It has degree 3 because the exponent of the second derivative is 3. Since the first (or second) derivative is not of degree 1, the differential equation is nonlinear.
13. The differential equation $\frac{d^2y}{ds^2} + 3s \frac{dy}{ds} - y = 0$ is second-order because the highest-order derivative is the second derivative. It has degree 1 because the exponent of the second derivative is 1. Since $P_0(s) = 1$, $P_1(s) = 3s$, and $P_2(s) = -1$ are all functions of s alone and no term contains more than one derivative, the differential equation is linear.
14. The differential equation $\frac{dy}{dx} = 1 - xy + y^2$ is first-order because the highest-order derivative is the first derivative. It has degree 1 because the exponent of the first derivative is 1. Since y^2 is not of degree 1, the differential equation is nonlinear.
15. For $y = e^x + 3e^{-x}$, we have $\frac{dy}{dx} = e^x - 3e^{-x}$ and $\frac{d^2y}{dx^2} = e^x + 3e^{-x}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} - y &= 0 \\ e^x + 3e^{-x} - (e^x + 3e^{-x}) &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

16. For $y = 5 \sin x + 2 \cos x$, we have $\frac{dy}{dx} = 5 \cos x - 2 \sin x$ and $\frac{d^2y}{dx^2} = -5 \sin x - 2 \cos x$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} + y &= 0 \\ -5 \sin x - 2 \cos x + 5 \sin x + 2 \cos x &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

17. For $y = \sin(2x)$, we have $\frac{dy}{dx} = 2 \cos(2x)$ and $\frac{d^2y}{dx^2} = -4 \sin(2x)$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} + 4y &= 0 \\ -4 \sin(2x) + 4 \sin(2x) &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

18. For $y = \cos(2x)$, we have $\frac{dy}{dx} = -2\sin(2x)$ and $\frac{d^2y}{dx^2} = -4\cos(2x)$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} + 4y &= 0 \\ -4\cos(2x) + 4\cos(2x) &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

19. For $y = \frac{3}{1-x^3}$, we have $\frac{dy}{dx} = \frac{9x^2}{(1-x^3)^2}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} &= x^2 y^2 \\ \frac{9x^2}{(1-x^3)^2} &= x^2 \left(\frac{3}{1-x^3} \right)^2 \\ \frac{9x^2}{(1-x^3)^2} &= x^2 \frac{9}{(1-x^3)^2}\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

20. For $y = 1 + Ce^{-x^2/2}$, C is a constant, we have $\frac{dy}{dx} = -Cxe^{-x^2/2}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} + xy &= x \\ -Cxe^{-x^2/2} + x(1 + Ce^{-x^2/2}) &= x \\ -Cxe^{-x^2/2} + x + Cxe^{-x^2/2} &= x \\ x &= x\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

21. For $y = e^{-2x}$, we have $y' = -2e^{-2x}$ and $y'' = 4e^{-2x}$. Substitute these into the differential equation:

$$\begin{aligned}y'' + 3y' + 2y &= 0 \\ 4e^{-2x} + 3(-2e^{-2x}) + 2(e^{-2x}) &= 0 \\ 4e^{-2x} - 6e^{-2x} + 2e^{-2x} &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

22. For $y = e^x$, we have $y' = e^x$ and $y'' = e^x$. Substitute these into the differential equation:

$$\begin{aligned}2y'' + y' - 3y &= 0 \\ 2e^x + e^x - 3e^x &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

23. Differentiate $y^2 + 2xy - x^2 = C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned}2y \frac{dy}{dx} + 2y + 2x \frac{dy}{dx} - 2x &= 0 \\ 2(x+y) \frac{dy}{dx} &= 2(x-y) \\ \frac{dy}{dx} &= \frac{x-y}{x+y}\end{aligned}$$

The function $y = f(x)$ defined by the equation $y^2 + 2xy - x^2 = C$ satisfies the first-order differential equation and so is a solution.

24. Solve for C in the equation $x^2 - y^2 = Cx^2y^2$. Differentiate $y^{-2} - x^{-2} = C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} -2y^{-3} \frac{dy}{dx} + 2x^{-3} &= 0 \\ -\frac{2}{y^3} \frac{dy}{dx} + \frac{2}{x^3} &= 0 \\ -\frac{2}{y^3} \frac{dy}{dx} &= -\frac{2}{x^3} \\ \frac{dy}{dx} &= \frac{y^3}{x^3} \end{aligned}$$

The function $y = f(x)$ defined by the equation $x^2 - y^2 = Cx^2y^2$ satisfies the first-order differential equation and so is a solution.

25. Solve for C in the equation $x^2 - y^2 = Cx$. Differentiate $\frac{x^2 - y^2}{x} = C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} \frac{x \left(2x - 2y \frac{dy}{dx} \right) - (x^2 - y^2)}{x^2} &= 0 \\ x \left(2x - 2y \frac{dy}{dx} \right) - (x^2 - y^2) &= 0 \\ 2x^2 - 2xy \frac{dy}{dx} - x^2 + y^2 &= 0 \\ -2xy \frac{dy}{dx} &= -x^2 - y^2 \\ \frac{dy}{dx} &= \frac{x^2 + y^2}{2xy} \end{aligned}$$

The function $y = f(x)$ defined by the equation $x^2 - y^2 = Cx$ satisfies the first-order differential equation and so is a solution.

26. Differentiate $x^2y + 12x^2 + 16y = 9$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} 2xy + x^2 \frac{dy}{dx} + 24x + 16 \frac{dy}{dx} &= 0 \\ (x^2 + 16) \frac{dy}{dx} &= -(2xy + 24x) \\ \frac{dy}{dx} &= -\frac{2xy + 24x}{x^2 + 16} \end{aligned}$$

The function $y = f(x)$ defined by the equation $x^2y + 12x^2 + 16y = 9$ satisfies the first-order differential equation and so is a solution.

27. Differentiate $2(x-1)e^x + y^2 = C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} 2e^x + 2(x-1)e^x + 2y\frac{dy}{dx} &= 0 \\ 2e^x + 2xe^x - 2e^x + 2y\frac{dy}{dx} &= 0 \\ 2y\frac{dy}{dx} &= -2xe^x \\ \frac{dy}{dx} &= -\frac{xe^x}{y} \end{aligned}$$

The function $y = f(x)$ defined by the equation $2(x-1)e^x + y^2 = C$ satisfies the first-order differential equation and so is a solution.

28. Differentiate $x^2 - y^2 + 2(e^{-x} - e^y) = C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} 2x - 2y\frac{dy}{dx} - 2e^{-x} - 2e^y\frac{dy}{dx} &= 0 \\ -2(y + e^y)\frac{dy}{dx} &= -2(x - e^{-x}) \\ \frac{dy}{dx} &= \frac{x - e^{-x}}{y + e^y} \end{aligned}$$

The function $y = f(x)$ defined by the equation $x^2 - y^2 + 2(e^{-x} - e^y) = C$ satisfies the first-order differential equation and so is a solution.

29. Differentiate $\tan^{-1} y = x + \frac{x^2}{2} + C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} \frac{1}{1+y^2}\frac{dy}{dx} &= 1+x \\ \frac{dy}{dx} &= (1+x)(1+y^2) \\ \frac{dy}{dx} &= xy^2 + y^2 + x + 1 \end{aligned}$$

The function $y = f(x)$ defined by the equation $\tan^{-1} y = x + \frac{x^2}{2} + C$ satisfies the first-order differential equation and so is a solution.

30. Solve for C in the equation $1 + 2y^2\sqrt{1+x^2} = Cy^2$. Differentiate $y^{-2} + 2\sqrt{1+x^2} = C$ implicitly with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} -\frac{2}{y^3}\frac{dy}{dx} + \frac{2x}{\sqrt{1+x^2}} &= 0 \\ -\frac{2}{y^3}\frac{dy}{dx} &= -\frac{2x}{\sqrt{1+x^2}} \\ \frac{dy}{dx} &= \frac{xy^3}{\sqrt{1+x^2}} \end{aligned}$$

The function $y = f(x)$ defined by the equation $1 + 2y^2\sqrt{1+x^2} = Cy^2$ satisfies the first-order differential equation and so is a solution.

Applications and Extensions

31. For $y = 3x$, we have $\frac{dy}{dx} = 3$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} &= \frac{y}{x} \\ 3 &= \frac{3x}{x}\end{aligned}$$

The function y satisfies the differential equation when $x \neq 0$ and so y is a solution. It further satisfies the initial condition: when $x = 1$, $y = 3 \cdot 1 = 3$.

32. For $y = 2e^{3x}$, we have $\frac{dy}{dx} = 6e^{3x}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} &= 3y \\ 6e^{3x} &= 3 \cdot 2e^{3x}\end{aligned}$$

The function y satisfies the differential equation and so y is a solution. It further satisfies the initial condition: when $x = 0$, $y = 2e^0 = 2 \cdot 1 = 2$.

33. For $y = \frac{1}{1-x}$, we have $\frac{dy}{dx} = \frac{1}{(1-x)^2}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} &= y^2 \\ \frac{1}{(1-x)^2} &= \left(\frac{1}{1-x}\right)^2\end{aligned}$$

The function y satisfies the differential equation and so y is a solution. It further satisfies the initial condition: when $x = 0$, $y = \frac{1}{1-0} = 1$.

34. For $y = \frac{x^2}{3} + \frac{3}{x}$, we have $\frac{dy}{dx} = \frac{2x}{3} - \frac{3}{x^2}$. Substitute these into the differential equation:

$$\begin{aligned}x \frac{dy}{dx} + y &= x^2 \\ x \left(\frac{2x}{3} - \frac{3}{x^2} \right) + \frac{x^2}{3} + \frac{3}{x} &= x^2 \\ \frac{2x^2}{3} - \frac{3}{x} + \frac{x^2}{3} + \frac{3}{x} &= x^2 \\ x^2 &= x^2\end{aligned}$$

The function y satisfies the differential equation and so y is a solution. It further satisfies the initial condition: when $x = 3$, $y = \frac{3^2}{3} + \frac{3}{3} = 3 + 1 = 4$.

35. For $y = C_1e^{ax} + C_2e^{-ax}$, C_1 and C_2 are constants, we have $\frac{dy}{dx} = aC_1e^{ax} - aC_2e^{-ax}$ and $\frac{d^2y}{dx^2} = a^2C_1e^{ax} + a^2C_2e^{-ax}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} - a^2y &= 0 \\ a^2C_1e^{ax} + a^2C_2e^{-ax} - a^2(C_1e^{ax} + C_2e^{-ax}) &= 0 \\ a^2C_1e^{ax} + a^2C_2e^{-ax} - a^2C_1e^{ax} - a^2C_2e^{-ax} &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

36. For $y = \sinh x$, we have $\frac{dy}{dx} = \cosh x$ and $\frac{d^2y}{dx^2} = \sinh x$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} &= y \\ \sinh x &= \sinh x\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

37. For $y = \frac{a^2kt}{1+akt}$, $a > 0$ and k are constants, we have

$$\frac{dy}{dt} = \frac{(1+akt)a^2k - a^2kt \cdot ak}{(1+akt)^2} = \frac{a^2k}{(1+akt)^2}$$

Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dt} &= k(a-y)^2 \\ \frac{a^2k}{(1+akt)^2} &= k\left(a - \frac{a^2kt}{1+akt}\right)^2 \\ \frac{a^2k}{(1+akt)^2} &= k\left(\frac{a+a^2kt}{1+akt} - \frac{a^2kt}{1+akt}\right)^2 \\ \frac{a^2k}{(1+akt)^2} &= k\left(\frac{a}{1+akt}\right)^2 \\ \frac{a^2k}{(1+akt)^2} &= k\frac{a^2}{(1+akt)^2} \\ \frac{a^2k}{(1+akt)^2} &= \frac{a^2k}{(1+akt)^2}\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

38. For $y = \ln(C - e^{-x})$, C is a constant, we have $\frac{dy}{dx} = \frac{e^{-x}}{C - e^{-x}}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} &= e^{-(x+y)} \\ \frac{e^{-x}}{C - e^{-x}} &= e^{-(x+\ln(C-e^{-x}))} \\ \frac{e^{-x}}{C - e^{-x}} &= e^{-x}e^{-\ln(C-e^{-x})} \\ \frac{e^{-x}}{C - e^{-x}} &= \frac{e^{-x}}{e^{\ln(C-e^{-x})}} \\ \frac{e^{-x}}{C - e^{-x}} &= \frac{e^{-x}}{C - e^{-x}}\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

39. For $y = e^{nx}$, n a constant, we have $y' = ne^{nx}$ and $y'' = n^2e^{nx}$. Substitute these into the differential equation:

$$\begin{aligned}y'' + y' - 6y &= 0 \\ n^2e^{nx} + ne^{nx} - 6e^{nx} &= 0 \\ e^{nx}(n^2 + n - 6) &= 0\end{aligned}$$

Since $e^{nx} \neq 0$, for the differential equation to be satisfied, it must be that $n^2 + n - 6 = (n+3)(n-2) = 0$. Solving for n , we have $n = -3$ or $n = 2$. For $y = e^{nx}$ to be a solution of $y'' + y' - 6y = 0$, $\boxed{n = -3 \text{ or } 2}$.

40. Answers will vary. The function $y = e^x + e^{-x}$ is a solution of the first-order differential equation $y' = e^x - e^{-x}$.
41. The Schrödinger equation $-\frac{h^2}{2m} \frac{d^2 Y(x)}{dx^2} + U(x)Y(x) = EY(x)$ is a second-order differential equation of degree 1. It is second-order because the highest-order derivative is the second derivative, and it is degree 1 because the exponent of the second derivative is 1.

16.2 Separation of Variables in First-Order Differential Equations

Concepts and Vocabulary

1. Express $\frac{dy}{dx} = xy$ in the differential form

$$\frac{1}{y} dy = x dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \frac{1}{y} dy &= \int x dx \\ \ln |y| &= 0.5x^2 + C_1 \\ e^{\ln |y|} &= e^{0.5x^2 + C_1} \\ |y| &= e^{0.5x^2} e^{C_1} \\ y &= \pm e^{0.5x^2} e^{C_1} \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm e^{C_1}$, where C is a nonzero constant. Then $y = Ce^{0.5x^2}$ is a general solution.

Notice that the function $y = 0$ also satisfies the differential equation $\frac{dy}{dx} = xy$, so it too is a solution. This particular solution matches the general solution above when $C = 0$. So the general solution of the differential equation $\frac{dy}{dx} = xy$ is $y = Ce^{0.5x^2}$ where C is any constant.

2. True. If $f(tx, ty) = t^k f(x, y)$, for all $t > 0$, where k is a real number, then the function f is said to be homogeneous of degree k in x and y .
3. If $F(x, y, C) = 0$ and $G(x, y, K) = 0$ are one-parameter families of curves in which each member of one family intersects the members of the other family orthogonally, then the two families are said to be orthogonal trajectories of each other.
4. If $M(x, y) dx + N(x, y) dy = 0$ is a homogeneous differential equation, then it can be transformed into an equation whose variables are separable by using the substitution $y = xv(x)$ where $v = v(x)$ is a differentiable function of x .

Skill Building

5. Express $\frac{dy}{dx} = x \sec y = \frac{x}{\cos y}$ in the differential form

$$\cos y dy = x dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \cos y dy &= \int x dx \\ \sin y &= \frac{1}{2}x^2 + C \end{aligned}$$

Then the general solution is $\boxed{\sin y = \frac{1}{2}x^2 + C}$, where C is a constant.

6. Express $\cos y \frac{dy}{dx} = \frac{2}{x}$ in the differential form

$$\cos y \, dy = \frac{2}{x} \, dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \cos y \, dy &= \int \frac{2}{x} \, dx \\ \sin y &= 2 \ln |x| + C \end{aligned}$$

Then the general solution is $\boxed{\sin y = 2 \ln |x| + C}$, where C is a constant.

7. Express $\frac{dy}{dx} = e^{y-x} = e^y e^{-x}$ in the differential form

$$e^{-y} \, dy = e^{-x} \, dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int e^{-y} \, dy &= \int e^{-x} \, dx \\ -e^{-y} &= -e^{-x} + C_1 \\ e^{-y} &= e^{-x} - C_1 \\ \ln(e^{-y}) &= \ln(e^{-x} - C_1) \\ -y &= \ln(e^{-x} - C_1) \\ y &= -\ln(e^{-x} - C_1) \end{aligned}$$

Since C_1 is a constant, we can write $C = -C_1$, where C is a constant. Then the general solution can be written as $\boxed{y = -\ln(e^{-x} + C)}$, where C is a constant.

8. Express $x \frac{dy}{dx} + 2y = 5$ first as $x \frac{dy}{dx} = 5 - 2y$, then in the differential form

$$\frac{1}{5-2y} \, dy = \frac{1}{x} \, dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \frac{1}{5-2y} \, dy &= \int \frac{1}{x} \, dx \\ -\frac{1}{2} \ln |5-2y| &= \ln |x| + C_1 \\ \ln |5-2y| &= -2 \ln |x| - 2C_1 \\ e^{\ln |5-2y|} &= e^{-2 \ln |x| - 2C_1} \\ |5-2y| &= e^{\ln |x|^{-2}} e^{-2C_1} \\ 5-2y &= \pm |x|^{-2} e^{-2C_1} \\ -2y &= -5 \pm \frac{e^{-2C_1}}{x^2} \\ y &= \frac{5}{2} \pm \frac{e^{-2C_1}}{2x^2} \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm \frac{e^{-2C_1}}{2}$, where C is a constant. Then the general solution can be written as $\boxed{y = \frac{5}{2} + \frac{C}{x^2}}$, where C is a constant.

9. Express $\frac{dy}{dx} = \cos x \frac{dy}{dx} - y \sin x$ first as $(1 - \cos x) \frac{dy}{dx} = -y \sin x$, then in the differential form

$$\frac{1}{y} dy = -\frac{\sin x}{1 - \cos x} dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \frac{1}{y} dy &= \int \left(-\frac{\sin x}{1 - \cos x} \right) dx && \text{Use } u = 1 - \cos x. \\ \ln |y| &= -\ln |1 - \cos x| + C_1 \\ e^{\ln |y|} &= e^{-\ln |1 - \cos x| + C_1} \\ |y| &= e^{-\ln |1 - \cos x|} e^{C_1} \\ y &= \pm \frac{e^{C_1}}{e^{\ln |1 - \cos x|}} \\ y &= \pm \frac{e^{C_1}}{|1 - \cos x|} \\ y &= \pm \frac{e^{C_1}}{1 - \cos x} \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm e^{C_1}$, where C is a constant. Then the general solution can be written as $y = \frac{C}{1 - \cos x}$, where $C \neq 0$ is a constant.

Notice that the function $y = 0$ also satisfies the differential equation $\frac{dy}{dx} = \cos x \frac{dy}{dx} - y \sin x$, so it too is a solution. This particular solution matches the general solution above when $C = 0$. So the general solution is $\boxed{y = \frac{C}{1 - \cos x}}$, where C is any constant.

10. Express $\frac{dy}{dx} = x + y \frac{dy}{dx}$ first as $(1 - y) \frac{dy}{dx} = x$, then in the differential form

$$(1 - y) dy = x dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int (1 - y) dy &= \int x dx \\ y - \frac{1}{2} y^2 &= \frac{1}{2} x^2 + C \end{aligned}$$

Then the general solution is $\boxed{y - \frac{1}{2} y^2 = \frac{1}{2} x^2 + C}$, where C is a constant.

11. Express $\frac{dy}{dx} + xy = x$ first as $\frac{dy}{dx} = x - xy = x(1 - y)$, then in the differential form

$$\frac{1}{1 - y} dy = x dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \frac{1}{1 - y} dy &= \int x dx \\ -\ln |1 - y| &= 0.5x^2 + C_1 \\ \ln |1 - y| &= -0.5x^2 - C_1 \\ e^{\ln |1 - y|} &= e^{-0.5x^2 - C_1} \\ |1 - y| &= e^{-0.5x^2} e^{-C_1} \\ 1 - y &= \pm e^{-0.5x^2} e^{-C_1} \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm e^{-C_1}$, where C is a nonzero constant. Solve for y in the equation $1 - y = Ce^{-0.5x^2}$. Then the general solution is $y = 1 - Ce^{-0.5x^2}$, where $C \neq 0$ is a constant.

Notice that the function $y = 1$ also satisfies the differential equation $\frac{dy}{dx} + xy = x$, so it too is a solution. This particular solution matches the general solution above when $C = 0$. So the general solution is

$$\boxed{y = 1 - Ce^{-0.5x^2}}, \text{ where } C \text{ is any constant.}$$

12. Express $(3x + 1)dx + e^{x+y}dy = 0$ first as $(3x + 1)dx + e^x e^y dy = 0$, then as $(3x + 1)e^{-x}dx + e^y dy = 0$. Integrate to obtain the general solution.

$$\begin{aligned} \int (3x + 1)e^{-x}dx + \int e^y dy &= 0 && \text{Use integration by parts.} \\ -(3x + 4)e^{-x} + e^y + C &= 0 \end{aligned}$$

Then the general solution is $\boxed{-(3x + 4)e^{-x} + e^y + C = 0}$, where C is a constant.

13. Express $\ln x \frac{dx}{dy} = \frac{x}{y}$ in the differential form

$$\frac{\ln x}{x} dx = \frac{1}{y} dy$$

Integrate to obtain the general solution.

$$\begin{aligned} \int \frac{\ln x}{x} dx &= \int \frac{1}{y} dy \\ \frac{1}{2}(\ln x)^2 &= \ln |y| + C_1 \\ \frac{1}{2}(\ln x)^2 - C_1 &= \ln |y| \\ e^{[1/2(\ln x)^2 - C_1]} &= |y| \\ e^{1/2(\ln x)^2} e^{-C_1} &= |y| \\ \pm e^{1/2(\ln x)^2} e^{-C_1} &= y \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm e^{-C_1}$, where C is a nonzero constant.

$$\begin{aligned} y &= Ce^{1/2(\ln x)^2} \\ &= C \left((e^{\ln x})^{1/2} \right)^{\ln x} \\ &= C \left((x)^{1/2} \right)^{\ln x} \\ &= C (\sqrt{x})^{\ln x} \end{aligned}$$

Then the general solution $\boxed{y = C (\sqrt{x})^{\ln x}}$ is where $C \neq 0$ is a constant.

14. Express $\frac{dy}{dx} = \frac{x+2}{2-y}$ in the differential form

$$(2 - y)dy = (x + 2)dx$$

Integrate to obtain the general solution.

$$\begin{aligned} \int (2 - y)dy &= \int (x + 2)dx \\ 2y - \frac{1}{2}y^2 &= \frac{1}{2}x^2 + 2x + C \end{aligned}$$

Then the general solution is $\boxed{2y - \frac{1}{2}y^2 = \frac{1}{2}x^2 + 2x + C}$, where C is a constant.

15. The general solution of the differential equation $\frac{dy}{dx} = x \sec y$ is $\sin y = \frac{1}{2}x^2 + C$, see the solution to Problem 5. To find the particular solution, substitute $x = 1$ and $y = \frac{\pi}{4}$ and solve for C .

$$\begin{aligned}\sin y &= \frac{1}{2}x^2 + C \\ \sin \frac{\pi}{4} &= \frac{1}{2}1^2 + C \\ \frac{\sqrt{2}}{2} &= \frac{1}{2} + C \\ \frac{\sqrt{2} - 1}{2} &= C\end{aligned}$$

Solve for y in the equation $\sin y = \frac{1}{2}x^2 + \frac{\sqrt{2} - 1}{2}$. The particular solution is

$$\boxed{y = \sin^{-1} \left(\frac{1}{2}x^2 + \frac{\sqrt{2} - 1}{2} \right)}$$

16. The general solution of the differential equation $\cos y \frac{dy}{dx} = \frac{2}{x}$ is $\sin y = 2 \ln |x| + C$, see the solution to Problem 6. To find the particular solution, substitute $x = -1$ and $y = \frac{\pi}{3}$ and solve for C .

$$\begin{aligned}\sin y &= 2 \ln |x| + C \\ \sin \frac{\pi}{3} &= 2 \ln |-1| + C \\ \frac{\sqrt{3}}{2} &= 2 \cdot 0 + C \\ \frac{\sqrt{3}}{2} &= C\end{aligned}$$

The particular solution is

$$\boxed{\sin y = 2 \ln |x| + \frac{\sqrt{3}}{2}}$$

17. The general solution of the differential equation $\frac{dy}{dx} = e^{y-x}$ is $y = -\ln(e^{-x} + C)$, see the solution to Problem 7. To find the particular solution, substitute $x = 0$ and $y = 0$ and solve for C .

$$\begin{aligned}y &= -\ln(e^{-x} + C) \\ 0 &= -\ln(e^0 + C) \\ 0 &= -\ln(1 + C) \\ 0 &= \ln(1 + C) \\ e^0 &= 1 + C \\ 1 &= 1 + C \\ 0 &= C\end{aligned}$$

Replace C with zero to get $y = -\ln(e^{-x} + 0) = -\ln(e^{-x}) = -(-x) = x$. The particular solution is

$$\boxed{y = x}$$

18. The general solution of the differential equation $x \frac{dy}{dx} + 2y = 5$ is $y = \frac{5}{2} + \frac{C}{x^2}$, see the solution to Problem 8. To find the particular solution, substitute $x = -1$ and $y = 1$ and solve for C .

$$\begin{aligned} y &= \frac{5}{2} + \frac{C}{x^2} \\ 1 &= \frac{5}{2} + \frac{C}{(-1)^2} \\ 1 &= \frac{5}{2} + C \\ -\frac{3}{2} &= C \end{aligned}$$

The particular solution is

$$y = \frac{5}{2} - \frac{3}{2x^2}$$

19. The general solution of the differential equation $\frac{dy}{dx} = \cos x \frac{dy}{dx} - y \sin x$ is $y = \frac{C}{1 - \cos x}$, see the solution to Problem 9. To find the particular solution, substitute $x = \pi$ and $y = \frac{1}{2}$ and solve for C .

$$\begin{aligned} y &= \frac{C}{1 - \cos x} \\ \frac{1}{2} &= \frac{C}{1 - \cos \pi} \\ \frac{1}{2} &= \frac{C}{2} \\ 1 &= C \end{aligned}$$

The particular solution is

$$y = \frac{1}{1 - \cos x}$$

on the interval $0 < x < 2\pi$.

20. The general solution of the differential equation $\frac{dy}{dx} = x + y \frac{dy}{dx}$ is $y - \frac{1}{2}y^2 = \frac{1}{2}x^2 + C$, see the solution to Problem 10. To find the particular solution, substitute $x = 2$ and $y = 1$ and solve for C .

$$\begin{aligned} y - \frac{1}{2}y^2 &= \frac{1}{2}x^2 + C \\ 1 - \frac{1}{2}1^2 &= \frac{1}{2}2^2 + C \\ \frac{1}{2} &= 2 + C \\ -\frac{3}{2} &= C \end{aligned}$$

The particular solution is

$$y - \frac{1}{2}y^2 = \frac{1}{2}x^2 - \frac{3}{2}$$

21. $f(x, y) = 2x^2 - 3xy - y^2$ is a homogeneous function of degree 2, since

$$\begin{aligned} f(tx, ty) &= 2(tx)^2 - 3(tx)(ty) - (ty)^2 = 2t^2x^2 - 3t^2xy - t^2y^2 \\ &= t^2(2x^2 - 3xy - y^2) = t^2f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

22. $f(x, y) = x^3 - xy^2 + y^3$ is a homogeneous function of degree 3, since

$$\begin{aligned} f(tx, ty) &= (tx)^3 - (tx)(ty)^2 + (ty)^3 \\ &= t^3(x^3 - xy^2 + y^3) = t^3 f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

23. $f(x, y) = x^3 - xy + y^3$ is not a homogeneous function, since

$$f(tx, ty) = (tx)^3 - (tx)(ty) + (ty)^3 = t^2(tx^3 - xy + ty^3) \neq t^k(x^3 - xy + y^3)$$

for all $t > 0$ and some k .

24. $f(x, y) = x^2 - xy^2 + y^2$ is not a homogeneous function, since

$$f(tx, ty) = (tx)^2 - tx(ty)^2 + (ty)^2 = t^2(x^2 - txy^2 + y^2) \neq t^k(x^2 - xy^2 + y^2)$$

for all $t > 0$ and some k .

25. $f(x, y) = 2x + \sqrt{x^2 + y^2}$ is a homogeneous function of degree 1, since

$$\begin{aligned} f(tx, ty) &= 2tx + \sqrt{(tx)^2 + (ty)^2} \\ &= 2tx + \sqrt{t^2(x^2 + y^2)} \\ &= 2tx + \sqrt{t^2} \sqrt{x^2 + y^2} \\ &= 2tx + t\sqrt{x^2 + y^2} \\ &= t(2x + \sqrt{x^2 + y^2}) = t f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

26. $f(x, y) = \sqrt{x + y}$ is a homogeneous function of degree 1/2, since

$$\begin{aligned} f(tx, ty) &= \sqrt{tx + ty} \\ &= \sqrt{t(x + y)} \\ &= \sqrt{t} \sqrt{x + y} \\ &= t^{1/2} \sqrt{x + y} = t^{1/2} f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

27. $f(x, y) = \tan\left(\frac{3x}{y}\right)$ is a homogeneous function of degree 0, since

$$\begin{aligned} f(tx, ty) &= \tan\left(\frac{3tx}{ty}\right) \\ &= t^0 \left(\tan\left(\frac{3x}{y}\right) \right) = t^0 f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

28. $f(x, y) = e^{x/y}$ is a homogeneous function of degree 0, since

$$\begin{aligned} f(tx, ty) &= e^{tx/ty} \\ &= t^0 e^{x/y} = t^0 f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

29. $f(x, y) = \ln \frac{x}{y}$ is a homogeneous function of degree 0, since

$$\begin{aligned} f(tx, ty) &= \ln \frac{tx}{ty} \\ &= t^0 \ln \frac{x}{y} = t^0 f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

30. $f(x, y) = x \ln x - x \ln y$ is a homogeneous function of degree 1, since

$$\begin{aligned} f(tx, ty) &= tx \ln tx - tx \ln ty \\ &= tx(\ln tx - \ln ty) \\ &= tx \ln \frac{tx}{ty} \\ &= tx \ln \frac{x}{y} \\ &= t(x \ln x - x \ln y) \\ &= t^1 f(x, y) \end{aligned}$$

for all $t > 0$.

31. Both $x - y$ and x are homogeneous of degree 1. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} (x - y) dx + x dy &= 0 \\ (x - xv) dx + x(x dv + v dx) &= 0 \\ x dx + x^2 dv &= 0 \end{aligned}$$

For $x \neq 0$, separate the variables by dividing by x^2 , then integrate.

$$\begin{aligned} \frac{1}{x} dx + dv &= 0 \\ \int \frac{1}{x} dx + \int dv &= 0 \\ \ln |x| + v &= C \\ \ln |x| + \frac{y}{x} &= C \\ x \ln |x| + y &= Cx \\ y &= Cx - x \ln |x| \end{aligned}$$

Then the general solution is $y = Cx - x \ln |x|$, where C is a constant.

32. Both $x + y$ and x are homogeneous of degree 1. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} (x + y) dx + x dy &= 0 \\ (x + xv) dx + x(x dv + v dx) &= 0 \\ (x + 2xv) dx + x^2 dv &= 0 \\ x(1 + 2v) dx + x^2 dv &= 0 \end{aligned}$$

For $x \neq 0$ and $v \neq -1/2$, we can separate the variables by dividing by x^2 and $1 + 2v$.

$$\begin{aligned} x(1 + 2v) dx + x^2 dv &= 0 \\ \frac{x(1 + 2v)}{x^2(1 + 2v)} dx + \frac{x^2}{x^2(1 + 2v)} dv &= 0 \\ \frac{1}{x} dx + \frac{1}{1 + 2v} dv &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned}
 \int \frac{1}{x} dx + \int \frac{1}{1+2v} dv &= 0 \\
 \ln|x| + \frac{1}{2} \ln|1+2v| &= C_1 \\
 2 \ln|x| + \ln|1+2v| &= 2C_1 \\
 \ln|x^2| + \ln|1+2v| &= 2C_1 \\
 \ln|x^2(1+2v)| &= 2C_1 \\
 |x^2(1+2v)| &= e^{2C_1} \\
 x^2(1+2v) &= \pm e^{2C_1} \\
 x^2(1+2\frac{y}{x}) &= \pm e^{2C_1} \\
 x^2 + 2xy &= \pm e^{2C_1} \\
 2xy &= -x^2 \pm e^{2C_1} \\
 y &= -\frac{1}{2}x \pm \frac{e^{2C_1}}{2x}
 \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm \frac{e^{2C_1}}{2}$, where C is a nonzero constant. Then the general solution can be written as $y = -\frac{1}{2}x + \frac{C}{x}$, where $C \neq 0$ is a constant.

Notice that the function $y = -\frac{1}{2}x$ also satisfies the differential equation $(x+y) + x \frac{dy}{dx} = 0$, so it too is a solution. This particular solution matches the general solution above when $C = 0$. Then the general solution is $\boxed{y = -\frac{1}{2}x + \frac{C}{x}}$, where C is a constant.

33. Both $x^2 + y^2$ and $x^2 - xy$ are homogeneous of degree 2. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}
 (x^2 + y^2) dx + (x^2 - xy) dy &= 0 \\
 (x^2 + (xv)^2) dx + (x^2 - x(xv))(x dv + v dx) &= 0 \\
 (x^2 + x^2v) dx + (x^3 - x^3v) dv &= 0 \\
 x^2(1+v) dx + x^3(1-v) dv &= 0
 \end{aligned}$$

For $x \neq 0$ and $v \neq -1$, we can separate the variables by dividing by x^3 and $1+v$.

$$\begin{aligned}
 x^2(1+v) dx + x^3(1-v) dv &= 0 \\
 \frac{x^2(1+v)}{x^3(1+v)} dx + \frac{x^3(1-v)}{x^3(1+v)} dv &= 0 \\
 \frac{1}{x} dx + \frac{1-v}{1+v} dv &= 0
 \end{aligned}$$

Integrate.

$$\begin{aligned}
 \int \frac{1}{x} dx + \int \frac{1-v}{1+v} dv &= 0 \\
 \int \frac{1}{x} dx + \int \left(-1 + \frac{2}{1+v} \right) dv &= 0 \\
 \ln |x| - v + 2 \ln |1+v| &= C \\
 \ln |x| - \frac{y}{x} + 2 \ln \left| 1 + \frac{y}{x} \right| &= C \\
 \ln |x| - \frac{y}{x} + 2 \ln \left| \frac{x+y}{x} \right| &= C \\
 \ln |x| - \frac{y}{x} + 2 \ln |x+y| - 2 \ln |x| &= C \\
 2 \ln |x+y| - \ln |x| - \frac{y}{x} &= C
 \end{aligned}$$

Then the general solution is $\boxed{\frac{y}{x} - 2 \ln |x+y| + \ln |x| + C = 0}$, where C is a constant.

34. Both xy and $x^2 + y^2$ are homogeneous of degree 2. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}
 xy dx + (x^2 + y^2) dy &= 0 \\
 x(xv) dx + (x^2 + (xv)^2)(x dv + v dx) &= 0 \\
 (2x^2v + x^2v^3) dx + (x^3 + x^3v^2) dv &= 0 \\
 x^2(2v + v^3) dx + x^3(1 + v^2) dv &= 0
 \end{aligned}$$

For $x \neq 0$ and $v \neq 0$, we can separate the variables by dividing by x^3 and $2v + v^3$.

$$\begin{aligned}
 x^2(2v + v^3) dx + x^3(1 + v^2) dv &= 0 \\
 \frac{x^2(2v + v^3)}{x^3(2v + v^3)} dx + \frac{x^3(1 + v^2)}{x^3(2v + v^3)} dv &= 0 \\
 \frac{1}{x} dx + \frac{1 + v^2}{2v + v^3} dv &= 0
 \end{aligned}$$

Integrate using a partial fraction decomposition.

$$\begin{aligned}
 \int \frac{1}{x} dx + \int \frac{1 + v^2}{2v + v^3} dv &= 0 \\
 \int \frac{1}{x} dx + \frac{1}{2} \int \left(\frac{1}{v} + \frac{v}{2 + v^2} \right) dv &= 0 \\
 \ln |x| + \frac{1}{2} \ln |v| + \frac{1}{4} \ln |2 + v^2| &= C_1 \\
 4 \ln |x| + 2 \ln |v| + \ln |2 + v^2| &= 4C_1 \\
 4 \ln |x| + 2 \ln \left| \frac{y}{x} \right| + \ln \left| 2 + \frac{y^2}{x^2} \right| &= 4C_1 \\
 4 \ln |x| + 2 \ln \left| \frac{y}{x} \right| + \ln \left| \frac{2x^2 + y^2}{x^2} \right| &= 4C_1 \\
 4 \ln |x| + 2 \ln |y| - 2 \ln |x| + \ln |2x^2 + y^2| - \ln |x^2| &= 4C_1 \\
 4 \ln |x| + 2 \ln |y| - 2 \ln |x| + \ln |2x^2 + y^2| - 2 \ln |x| &= 4C_1 \\
 2 \ln |y| + \ln |2x^2 + y^2| &= 4C_1
 \end{aligned}$$

Since C_1 is a constant, we can write $C = 4C_1$, where C is a constant. Then the general solution is $\boxed{2 \ln |y| + \ln |2x^2 + y^2| = C}$, where C is a constant.

35. Write the differential equation $\frac{dy}{dx} = \frac{y-x}{y+x}$ in the form $(y+x)dy = (y-x)dx$. Both $y+x$ and $y-x$ are homogeneous of degree 1. Let $y = xv$. Then $dy = xdv + vdx$. Substitute these into the differential equation:

$$\begin{aligned}(y+x)dy &= (y-x)dx \\(xv+x)(xdv+vdx) &= (xv-x)dx \\(xv^2+x)dx + (x^2v+x^2)dv &= 0 \\x(v^2+1)dx + x^2(v+1)dv &= 0\end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^2 and v^2+1 .

$$\begin{aligned}x(v^2+1)dx + x^2(v+1)dv &= 0 \\ \frac{x(v^2+1)}{x^2(v^2+1)}dx + \frac{x^2(v+1)}{x^2(v^2+1)}dv &= 0 \\ \frac{1}{x}dx + \frac{v+1}{v^2+1}dv &= 0\end{aligned}$$

Integrate.

$$\begin{aligned}\int \frac{1}{x}dx + \int \frac{v+1}{v^2+1}dv &= 0 \\ \int \frac{1}{x}dx + \int \frac{v}{v^2+1}dv + \int \frac{1}{v^2+1}dv &= 0 \\ \ln|x| + \frac{1}{2}\ln(v^2+1) + \tan^{-1}v &= C \\ \ln|x| + \frac{1}{2}\ln\left(\frac{y^2}{x^2}+1\right) + \tan^{-1}\left(\frac{y}{x}\right) &= C \\ \ln|x| + \frac{1}{2}\ln\left(\frac{x^2+y^2}{x^2}\right) + \tan^{-1}\left(\frac{y}{x}\right) &= C \\ \ln|x| + \frac{1}{2}\ln(x^2+y^2) - \frac{1}{2}\ln x^2 + \tan^{-1}\left(\frac{y}{x}\right) &= C \\ \ln|x| + \frac{1}{2}\ln(x^2+y^2) - \ln\sqrt{x^2} + \tan^{-1}\left(\frac{y}{x}\right) &= C \\ \ln|x| + \frac{1}{2}\ln(x^2+y^2) - \ln|x| + \tan^{-1}\left(\frac{y}{x}\right) &= C \\ \frac{1}{2}\ln(x^2+y^2) + \tan^{-1}\left(\frac{y}{x}\right) &= C\end{aligned}$$

Then the general solution is $\boxed{\frac{1}{2}\ln(x^2+y^2) + \tan^{-1}\left(\frac{y}{x}\right) = C}$, where C is a constant.

36. Write the differential equation $\frac{dy}{dx} = \frac{x+2y}{2x+y}$ in the form $(2x+y)dy = (x+2y)dx$. Both $2x+y$ and $x+2y$ are homogeneous of degree 1. Let $y = xv$. Then $dy = xdv + vdx$. Substitute these into the differential equation:

$$\begin{aligned}(2x+y)dy &= (x+2y)dx \\(2x+xv)(xdv+vdx) &= (x+2xv)dx \\(xv^2-x)dx + (2x^2+x^2v)dv &= 0 \\x(v^2-1)dx + x^2(2+v)dv &= 0\end{aligned}$$

For $x \neq 0$ and $v \neq \pm 1$, we can separate the variables by dividing by x^2 and $v^2 - 1$.

$$\begin{aligned} x(v^2 - 1) dx + x^2(2 + v) dv &= 0 \\ \frac{x(v^2 - 1)}{x^2(v^2 - 1)} dx + \frac{x^2(2 + v)}{x^2(v^2 - 1)} dv &= 0 \\ \frac{1}{x} dx + \frac{2 + v}{v^2 - 1} dv &= 0 \end{aligned}$$

Integrate using a partial fraction decomposition.

$$\begin{aligned} \int \frac{1}{x} dx + \int \frac{2 + v}{v^2 - 1} dv &= 0 \\ \int \frac{1}{x} dx + \int \left(\frac{3}{2} \frac{1}{v - 1} - \frac{1}{2} \frac{1}{v + 1} \right) dv &= 0 \\ \ln |x| + \frac{3}{2} \ln |v - 1| - \frac{1}{2} \ln |v + 1| &= C_1 \\ 2 \ln |x| + 3 \ln |v - 1| - \ln |v + 1| &= 2C_1 \\ 2 \ln |x| + 3 \ln \left| \frac{y}{x} - 1 \right| - \ln \left| \frac{y}{x} + 1 \right| &= 2C_1 \\ 2 \ln |x| + 3 \ln \left| \frac{y - x}{x} \right| - \ln \left| \frac{x + y}{x} \right| &= 2C_1 \\ 2 \ln |x| + 3 \ln |y - x| - 3 \ln |x| - \ln |x + y| + \ln |x| &= 2C_1 \\ 3 \ln |y - x| - \ln |x + y| &= 2C_1 \end{aligned}$$

Since C_1 is a constant, we can write $C = 2C_1$, where C is a constant. Then the general solution is $\boxed{3 \ln |y - x| - \ln |x + y| = C}$, where C is a constant.

37. Write the differential equation $x \frac{dy}{dx} = x + y$ in the form $x dy = (x + y) dx$. Both x and $x + y$ are homogeneous of degree 1. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} x dy &= (x + y) dx \\ x(x dv + v dx) &= (x + xv) dx \\ -x dx + x^2 dv &= 0 \end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^2 .

$$\begin{aligned} -x dx + x^2 dv &= 0 \\ -\frac{1}{x} dx + dv &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned} -\int \frac{1}{x} dx + \int dv &= 0 \\ -\ln |x| + v &= C \\ -\ln |x| + \frac{y}{x} &= C \\ -x \ln |x| + y &= Cx \\ y &= x \ln |x| + Cx = x(C + \ln |x|) \end{aligned}$$

Then the general solution is $\boxed{y = x(C + \ln |x|)}$, where C is a constant.

38. Write the differential equation $x(x^2 - y^2) \frac{dy}{dx} - y(x^2 + y^2) = 0$ in the form $x(x^2 - y^2) dy - y(x^2 + y^2) dx = 0$. Both $x(x^2 - y^2)$ and $-y(x^2 + y^2)$ are homogeneous of degree 3. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} x(x^2 - y^2) dy - y(x^2 + y^2) dx &= 0 \\ x(x^2 - (xv)^2)(x dv + v dx) - xv(x^2 + (xv)^2) dx &= 0 \\ -2x^3v^3 dx + (x^4 - x^4v^2) dv &= 0 \\ -2x^3v^3 dx + x^4(1 - v^2) dv &= 0 \end{aligned}$$

For $x \neq 0$ and $v \neq 0$, we can separate the variables by dividing by $-x^4$ and v^3 .

$$\begin{aligned} -2x^3v^3 dx + x^4(1 - v^2) dv &= 0 \\ \frac{-2x^3v^3}{-x^4v^3} dx + \frac{x^4(1 - v^2)}{-x^4v^3} dv &= 0 \\ \frac{2}{x} dx + \frac{v^2 - 1}{v^3} dv &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned} \int \frac{2}{x} dx + \int \frac{v^2 - 1}{v^3} dv &= 0 \\ \int \frac{2}{x} dx + \int \left(\frac{1}{v} - v^{-3} \right) dv &= 0 \\ 2 \ln |x| + \ln |v| + \frac{1}{2} v^{-2} &= C \\ 2 \ln |x| + \ln \left| \frac{y}{x} \right| + \frac{1}{2} \left(\frac{y}{x} \right)^{-2} &= C \\ 2 \ln |x| + \ln |y| - \ln |x| + \frac{1}{2} \left(\frac{x}{y} \right)^2 &= C \\ \ln |x| + \ln |y| + \frac{x^2}{2y^2} &= C \end{aligned}$$

Then the general solution is $\boxed{\ln |x| + \ln |y| + \frac{x^2}{2y^2} = C}$, where C is a constant.

39. Write the differential equation $\frac{dy}{dx} = \frac{2xy}{x^2 + y^2}$ in the form $(x^2 + y^2) dy = 2xy dx$. Both $x^2 + y^2$ and $2xy$ are homogeneous of degree 2. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} (x^2 + y^2) dy &= 2xy dx \\ (x^2 + (xv)^2)(x dv + v dx) &= 2x(xv) dx \\ (x^2v^3 - x^2v) dx + (x^3 + x^3v^2) dv &= 0 \\ x^2(v^3 - v) dx + x^3(1 + v^2) dv &= 0 \end{aligned}$$

For $x \neq 0$ and $v \neq 0, \pm 1$, we can separate the variables by dividing by x^3 and $v^3 - v$.

$$\begin{aligned} x^2(v^3 - v) dx + x^3(1 + v^2) dv &= 0 \\ \frac{x^2(v^3 - v)}{x^3(v^3 - v)} dx + \frac{x^3(1 + v^2)}{x^3(v^3 - v)} dv &= 0 \\ \frac{1}{x} dx + \frac{1 + v^2}{v^3 - v} dv &= 0 \end{aligned}$$

Integrate using a partial fraction decomposition.

$$\begin{aligned}
 \int \frac{1}{x} dx + \int \frac{1+v^2}{v^3-v} dv &= 0 \\
 \int \frac{1}{x} dx + \int \left(-\frac{1}{v} + \frac{1}{v-1} + \frac{1}{v+1} \right) dv &= 0 \\
 \ln|x| - \ln|v| + \ln|v-1| + \ln|v+1| &= C_1 \\
 \ln|x| - \ln\left|\frac{y}{x}\right| + \ln\left|\frac{y}{x}-1\right| + \ln\left|\frac{y}{x}+1\right| &= C_1 \\
 \ln|x| - \ln\left|\frac{y}{x}\right| + \ln\left|\frac{y-x}{x}\right| + \ln\left|\frac{y+x}{x}\right| &= C_1 \\
 \ln|x| + \ln\left|\frac{x}{y}\right| + \ln\left|\frac{y-x}{x}\right| + \ln\left|\frac{y+x}{x}\right| &= C_1 \\
 \ln\left|x \cdot \frac{x}{y} \cdot \frac{y-x}{x} \cdot \frac{y+x}{x}\right| &= C_1 \\
 \ln\left|\frac{y^2-x^2}{y}\right| &= C_1 \\
 \left|\frac{y^2-x^2}{y}\right| &= e^{C_1} \\
 \frac{y^2-x^2}{y} &= \pm e^{C_1}
 \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm e^{C_1}$, where C is a nonzero constant. Then the general solution can be written as $\frac{y^2-x^2}{y} = C$, where $C \neq 0$ is a constant.

Notice that the functions $y = x$ and $y = -x$ also satisfy the differential equation $\frac{dy}{dx} = \frac{2xy}{x^2+y^2}$, so they are also solutions. These particular solutions arise in the general solution above when $C = 0$. Then

the general solution is $\boxed{\frac{y^2-x^2}{y} = C}$, where C is a constant.

40. Write the differential equation $\frac{dy}{dx} = \frac{x+2y}{2x-y}$ in the form $(2x-y)dy = (x+2y)dx$. Both $2x-y$ and $x+2y$ are homogeneous of degree 1. Let $y = xv$. Then $dy = xdv + vdx$. Substitute these into the differential equation:

$$\begin{aligned}
 (2x-y)dy &= (x+2y)dx \\
 (2x-xv)(xdv+vdx) &= (x+2xv)dx \\
 (-xv^2-x)dx + (2x^2-x^2v)dv &= 0 \\
 x(-v^2-1)dx + x^2(2-v)dv &= 0
 \end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^2 and $-v^2-1$.

$$\begin{aligned}
 x(-v^2-1)dx + x^2(2-v)dv &= 0 \\
 \frac{x(-v^2-1)}{x^2(-v^2-1)}dx + \frac{x^2(2-v)}{x^2(-v^2-1)}dv &= 0 \\
 \frac{1}{x}dx + \frac{v-2}{v^2+1}dv &= 0
 \end{aligned}$$

Integrate.

$$\begin{aligned}
 \int \frac{1}{x} dx + \int \frac{v-2}{v^2+1} dv &= 0 \\
 \int \frac{1}{x} dx + \int \left(\frac{v}{v^2+1} - \frac{2}{v^2+1} \right) dv &= 0 \\
 \ln |x| + \frac{1}{2} \ln(v^2+1) - 2 \tan^{-1} v &= C \\
 \ln |x| + \frac{1}{2} \ln \left(\frac{y^2}{x^2} + 1 \right) - 2 \tan^{-1} \left(\frac{y}{x} \right) &= C \\
 \ln |x| + \frac{1}{2} \ln \left(\frac{x^2+y^2}{x^2} \right) - 2 \tan^{-1} \left(\frac{y}{x} \right) &= C \\
 \ln |x| + \frac{1}{2} \ln(x^2+y^2) - \frac{1}{2} \ln(x^2) - 2 \tan^{-1} \left(\frac{y}{x} \right) &= C \\
 \ln |x| + \frac{1}{2} \ln(x^2+y^2) - \ln(\sqrt{x^2}) - 2 \tan^{-1} \left(\frac{y}{x} \right) &= C \\
 \ln |x| + \frac{1}{2} \ln(x^2+y^2) - \ln |x| - 2 \tan^{-1} \left(\frac{y}{x} \right) &= C \\
 \frac{1}{2} \ln(x^2+y^2) - 2 \tan^{-1} \left(\frac{y}{x} \right) &= C
 \end{aligned}$$

Then the general solution is $\boxed{\frac{1}{2} \ln(x^2+y^2) - 2 \tan^{-1} \left(\frac{y}{x} \right) = C}$, where C is a constant.

41. Write the differential equation $x^2 \frac{dy}{dx} = x^2 + xy - 4y^2$ in the form $x^2 dy = (x^2 + xy - 4y^2) dx$. Both x^2 and $x^2 + xy - 4y^2$ are homogeneous of degree 2. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}
 x^2 dy &= (x^2 + xy - 4y^2) dx \\
 x^2(x dv + v dx) &= (x^2 + x(xv) - 4(xv)^2) dx \\
 (4x^2v^2 - x^2) dx + x^3 dv &= 0 \\
 x^2(4v^2 - 1) dx + x^3 dv &= 0
 \end{aligned}$$

For $x \neq 0$ and $v \neq \pm 1/2$, we can separate the variables by dividing by x^3 and $4v^2 - 1$.

$$\begin{aligned}
 x^2(4v^2 - 1) dx + x^3 dv &= 0 \\
 \frac{x^2(4v^2 - 1)}{x^3(4v^2 - 1)} dx + \frac{x^3}{x^3(4v^2 - 1)} dv &= 0 \\
 \frac{1}{x} dx + \frac{1}{4v^2 - 1} dv &= 0
 \end{aligned}$$

Integrate using a partial fraction decomposition.

$$\begin{aligned}
 \int \frac{1}{x} dx + \int \frac{1}{4v^2 - 1} dv &= 0 \\
 \int \frac{1}{x} dx + \frac{1}{2} \int \left(\frac{1}{2v - 1} - \frac{1}{2v + 1} \right) dv &= 0 \\
 \ln |x| + \frac{1}{4} \ln |2v - 1| - \frac{1}{4} \ln |2v + 1| &= C_1 \\
 4 \ln |x| + \ln |2v - 1| - \ln |2v + 1| &= 4C_1 \\
 4 \ln |x| + \ln \left| \frac{2y}{x} - 1 \right| - \ln \left| \frac{2y}{x} + 1 \right| &= 4C_1 \\
 4 \ln |x| + \ln \left| \frac{2y - x}{x} \right| - \ln \left| \frac{2y + x}{x} \right| &= 4C_1 \\
 \ln |x^4| + \ln \left| \frac{2y - x}{x} \right| + \ln \left| \frac{x}{2y + x} \right| &= 4C_1 \\
 \ln \left| x^4 \cdot \frac{2y - x}{x} \cdot \frac{x}{2y + x} \right| &= 4C_1 \\
 \ln \left| \frac{x^4(2y - x)}{2y + x} \right| &= 4C_1 \\
 \left| \frac{x^4(2y - x)}{2y + x} \right| &= e^{4C_1} \\
 \frac{x^4(2y - x)}{2y + x} &= \pm e^{4C_1}
 \end{aligned}$$

Since C_1 is a constant, we can write $C = \pm e^{4C_1}$, where $C \neq 0$ is a constant. Then the general solution is $\frac{x^4(2y - x)}{2y + x} = C$, where $C \neq 0$ is a constant.

To find the particular solution, substitute $x = -1$ and $y = 1$ and solve for C .

$$\begin{aligned}
 \frac{x^4(2y - x)}{2y + x} &= C \\
 \frac{(-1)^4(2 - (-1))}{2 - 1} &= C \\
 3 &= C
 \end{aligned}$$

The particular solution is $\boxed{\frac{x^4(2y - x)}{2y + x} = 3}$.

42. Write the differential equation $x(x^2 - y^2) \frac{dy}{dx} - y(x^2 + y^2) = 0$ in the form $x(x^2 - y^2) dy - y(x^2 + y^2) dx = 0$. Both $x(x^2 - y^2)$ and $-y(x^2 + y^2)$ are homogeneous of degree 3. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}
 x(x^2 - y^2) dy - y(x^2 + y^2) dx &= 0 \\
 x(x^2 - (xv)^2)(x dv + v dx) - xv(x^2 + (xv)^2) dx &= 0 \\
 -2x^3v^3 dx + (x^4 - x^4v^2) dv &= 0 \\
 -2x^3v^3 dx + x^4(1 - v^2) dv &= 0
 \end{aligned}$$

For $x \neq 0$ and $v \neq 0$, we can separate the variables by dividing by $-x^4$ and v^3 .

$$\begin{aligned} -2x^3v^3 dx + x^4(1-v^2) dv &= 0 \\ \frac{-2x^3v^3}{-x^4v^3} dx + \frac{x^4(1-v^2)}{-x^4v^3} dv &= 0 \\ \frac{2}{x} dx + \frac{v^2-1}{v^3} dv &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned} \int \frac{2}{x} dx + \int \frac{v^2-1}{v^3} dv &= 0 \\ \int \frac{2}{x} dx + \int \left(\frac{1}{v} - v^{-3} \right) dv &= 0 \\ 2 \ln |x| + \ln |v| + \frac{1}{2} v^{-2} &= C \\ 2 \ln |x| + \ln \left| \frac{y}{x} \right| + \frac{1}{2} \left(\frac{y}{x} \right)^{-2} &= C \\ 2 \ln |x| + \ln |y| - \ln |x| + \frac{1}{2} \left(\frac{x}{y} \right)^2 &= C \\ \ln |x| + \ln |y| + \frac{1}{2} \left(\frac{x^2}{y^2} \right) &= C \\ \ln |x| + \ln |y| + \frac{x^2}{2y^2} &= C \end{aligned}$$

To find the particular solution, substitute $x = -1$ and $y = -2$ and solve for C .

$$\begin{aligned} \ln |x| + \ln |y| + \frac{x^2}{2y^2} &= C \\ \ln |-1| + \ln |-2| + \frac{(-1)^2}{2(-2)^2} &= C \\ \ln(2) + \frac{1}{8} &= C \end{aligned}$$

The particular solution is $\boxed{\ln |x| + \ln |y| + \frac{x^2}{2y^2} = \ln(2) + \frac{1}{8}}$.

43. Find y' by differentiating $xy = C$ with respect to x .

$$\begin{aligned} xy' + y &= 0 \\ xy' &= -y \\ y' &= -\frac{y}{x} \end{aligned}$$

Replace y' with $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = \frac{x}{y}$$

The differential equation $\frac{dy}{dx} = \frac{x}{y}$ is separable and can be written as

$$y dy = x dx$$

Integrate to find the general solution.

$$\begin{aligned}\int y \, dy &= \int x \, dx \\ \frac{1}{2}y^2 &= \frac{1}{2}x^2 + K_1 \\ y^2 &= x^2 + 2K_1\end{aligned}$$

Since K_1 is a constant, we may write $K = 2K_1$, where K is a constant. The orthogonal trajectories for the family of curves $xy = C$ is the family $y^2 = x^2 + K$. To find the particular curves needed for the graph, substitute $x = 2$ and $y = 1$ into $xy = C$ and $y^2 = x^2 + K$ separately and solve for C and K . The graph of $xy = 2$ and $y^2 = x^2 - 3$ is shown.

44. Rewrite $y^2 = 2(C - x)$ in the form $x + \frac{1}{2}y^2 = C$. Find y' by differentiating $x + \frac{1}{2}y^2 = C$ with respect to x .

$$\begin{aligned}1 + yy' &= 0 \\ yy' &= -1 \\ y' &= -\frac{1}{y}\end{aligned}$$

Replace y' with $-\frac{1}{y}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = y$$

The differential equation $\frac{dy}{dx} = y$ is separable and can be written as

$$\frac{1}{y} dy = dx$$

Integrate to find the general solution.

$$\begin{aligned}\int \frac{1}{y} dy &= \int dx \\ \ln |y| &= x + K_1 \\ |y| &= e^{x+K_1} \\ |y| &= e^x e^{K_1} \\ y &= \pm e^x e^{K_1}\end{aligned}$$

Since K_1 is a constant, we can write $K = \pm e^{K_1}$, where K is a nonzero constant. Notice that $y = 0$ also satisfies the differential equation $y' = y$, so it too is a solution. This particular solution matches

the general solution when $K = 0$. The orthogonal trajectories for the family of curves $y^2 = 2(C - x)$ is the family $y = Ke^x$, where K is any constant. To find the particular curves needed for the graph, substitute $x = 2$ and $y = 1$ into $y^2 = 2(C - x)$ and $y = Ke^x$ separately and solve for C and K . The graph of $y^2 = 5 - 2x$ and $y = e^{-2}e^x$ is shown.

45. Rewrite $y = Cx^2$ in the form $\frac{y}{x^2} = C$. Find y' by differentiating $\frac{y}{x^2} = C$ with respect to x .

$$\begin{aligned}\frac{x^2 y' - y \cdot 2x}{x^4} &= 0 \\ x^2 y' - 2xy &= 0 \\ x^2 y' &= 2xy \\ y' &= \frac{2xy}{x^2} \\ y' &= \frac{2y}{x}\end{aligned}$$

Replace y' with $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = -\frac{x}{2y}$$

The differential equation $\frac{dy}{dx} = -\frac{x}{2y}$ is separable and can be written as

$$2y \, dy = -x \, dx$$

Integrate to find the general solution.

$$\begin{aligned}\int 2y \, dy &= -\int x \, dx \\ y^2 &= -\frac{1}{2}x^2 + K_1 \\ 2y^2 &= -x^2 + 2K_1 \\ x^2 + 2y^2 &= 2K_1\end{aligned}$$

Since K_1 is a constant, we can write $K = 2K_1$, where K is a constant. The orthogonal trajectories for the family of curves $y = Cx^2$ is the family $x^2 + 2y^2 = K$. To find the particular curves needed for the graph, substitute $x = 2$ and $y = 1$ into $y = Cx^2$ and $x^2 + 2y^2 = K$ separately and solve for C and K . The graph of $y = \frac{1}{4}x^2$ and $x^2 + 2y^2 = 6$ is shown.

46. Rewrite $x^2 = Cy^3$ in the form $\frac{x^2}{y^3} = C$. Find y' by differentiating $\frac{x^2}{y^3} = C$ with respect to x .

$$\begin{aligned}\frac{y^3 \cdot 2x - x^2 \cdot 3y^2 y'}{y^6} &= 0 \\ 2xy^3 - 3x^2 y^2 y' &= 0 \\ -3x^2 y^2 y' &= -2xy^3 \\ y' &= \frac{-2xy^3}{-3x^2 y^2} \\ y' &= \frac{2y}{3x}\end{aligned}$$

Replace y' with $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = -\frac{3x}{2y}$$

The differential equation $\frac{dy}{dx} = -\frac{3x}{2y}$ is separable and can be written as

$$2y \, dy = -3x \, dx$$

Integrate to find the general solution.

$$\begin{aligned}\int 2y \, dy &= -\int 3x \, dx \\ y^2 &= -\frac{3}{2}x^2 + K \\ \frac{3}{2}x^2 + y^2 &= K\end{aligned}$$

The orthogonal trajectories for the family of curves $x^2 = Cy^3$ is the family $\boxed{\frac{3}{2}x^2 + y^2 = K}$. To find the particular curves needed for the graph, substitute $x = 2$ and $y = 1$ into $x^2 = Cy^3$ and $\frac{3}{2}x^2 + y^2 = K$ separately and solve for C and K . The graph of $x^2 = 4y^3$ and $\frac{3}{2}x^2 + y^2 = 7$ is shown.

Applications and Extensions

47. Substitute $x = u + h$ and $y = v + k$ into the numerator $y - x - 3$ to eliminate the constant -3 : $(v + k) - (u + h) - 3 = v - u$ implies that $k - h - 3 = 0$. Substitute $x = u + h$ and $y = v + k$ into the denominator $y + x + 4$ to eliminate the constant 4 : $(v + k) + (u + h) + 4 = v + u$ implies that $k + h + 4 = 0$. Solve the system of equations

$$\begin{aligned} k - h &= 3 \\ k + h &= -4 \end{aligned}$$

to find $h = -\frac{7}{2}$ and $k = -\frac{1}{2}$.

Let $x = u - \frac{7}{2}$ and $y = v - \frac{1}{2}$. Then $\frac{dy}{dx} = \frac{dv}{du}$. Substitute these into the differential equation:

$$\begin{aligned} \frac{dy}{dx} &= \frac{y - x - 3}{y + x + 4} \\ \frac{dv}{du} &= \frac{v - u}{v + u} \\ (v + u) dv &= (v - u) du \end{aligned}$$

Both $v + u$ and $v - u$ are homogeneous of degree 1. Let $v = uw$. Then $dv = u dw + w du$. Substitute these into the differential equation.

$$\begin{aligned} (v + u) dv &= (v - u) du \\ (uw + u)(u dw + w du) &= (uw - u) du \\ (uw^2 + u) du + (u^2 w + u^2) dw &= 0 \\ u(w^2 + 1) du + u^2(w + 1) dw &= 0 \end{aligned}$$

For $u \neq 0$, we can separate the variables by dividing by u^2 and $w^2 + 1$.

$$\begin{aligned} u(w^2 + 1) du + u^2(w + 1) dw &= 0 \\ \frac{u(w^2 + 1)}{u^2(w^2 + 1)} du + \frac{u^2(w + 1)}{u^2(w^2 + 1)} dw &= 0 \\ \frac{1}{u} du + \frac{w + 1}{w^2 + 1} dw &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned}
 \int \frac{1}{u} du + \int \frac{w+1}{w^2+1} dw &= 0 \\
 \int \frac{1}{u} du + \int \left(\frac{w}{w^2+1} + \frac{1}{w^2+1} \right) dw &= 0 \\
 \ln |u| + \frac{1}{2} \ln(w^2+1) + \tan^{-1} w &= C_1 \\
 \ln |u| + \frac{1}{2} \ln \left(\frac{v^2}{u^2} + 1 \right) + \tan^{-1} \left(\frac{v}{u} \right) &= C_1 \quad w = \frac{v}{u} \\
 \ln |u| + \frac{1}{2} \ln \left(\frac{u^2+v^2}{u^2} \right) + \tan^{-1} \left(\frac{v}{u} \right) &= C_1 \\
 \ln |u| + \frac{1}{2} \ln(u^2+v^2) - \frac{1}{2} \ln(u^2) + \tan^{-1} \left(\frac{v}{u} \right) &= C_1 \\
 \ln |u| + \frac{1}{2} \ln(u^2+v^2) - \ln(\sqrt{u^2}) + \tan^{-1} \left(\frac{v}{u} \right) &= C_1 \\
 \ln |u| + \frac{1}{2} \ln(u^2+v^2) - \ln |u| + \tan^{-1} \left(\frac{v}{u} \right) &= C_1 \\
 \frac{1}{2} \ln(u^2+v^2) + \tan^{-1} \left(\frac{v}{u} \right) &= C_1 \\
 \frac{1}{2} \ln \left(\left(x + \frac{7}{2} \right)^2 + \left(y + \frac{1}{2} \right)^2 \right) + \tan^{-1} \left(\frac{y + \frac{1}{2}}{x + \frac{7}{2}} \right) &= C_1 \quad u = x + \frac{7}{2}, v = y + \frac{1}{2} \\
 \frac{1}{2} \ln \left(\left(\frac{2x+7}{2} \right)^2 + \left(\frac{2y+1}{2} \right)^2 \right) + \tan^{-1} \left(\frac{2y+1}{2x+7} \right) &= C_1 \\
 \frac{1}{2} \ln \left(\frac{(2x+7)^2}{4} + \frac{(2y+1)^2}{4} \right) + \tan^{-1} \left(\frac{2y+1}{2x+7} \right) &= C_1 \\
 \frac{1}{2} \ln((2x+7)^2 + (2y+1)^2) - \frac{1}{2} \ln 4 + \tan^{-1} \left(\frac{2y+1}{2x+7} \right) &= C_1 \\
 \frac{1}{2} \ln((2x+7)^2 + (2y+1)^2) - \ln \sqrt{4} + \tan^{-1} \left(\frac{2y+1}{2x+7} \right) &= C_1 \\
 \frac{1}{2} \ln((2x+7)^2 + (2y+1)^2) + \tan^{-1} \left(\frac{2y+1}{2x+7} \right) &= C_1 + \ln 2 = C
 \end{aligned}$$

Then the general solution is $\boxed{\frac{1}{2} \ln((2x+7)^2 + (2y+1)^2) + \tan^{-1} \left(\frac{2y+1}{2x+7} \right) = C}$, where C is a constant.

48. Substitute $x = u + h$ and $y = v + k$ into the numerator $x + 2y - 3$ to eliminate the constant -3 : $(u + h) + 2(v + k) - 3 = u + 2v$ implies that $h + 2k - 3 = 0$. Substitute $x = u + h$ and $y = v + k$ into the denominator $2x - y + 1$ to eliminate the constant 1 : $2(u + h) - (v + k) + 1 = 2u - v$ implies that $2h - k + 1 = 0$. Solve the system of equations

$$\begin{aligned}
 h + 2k &= 3 \\
 2h - k &= -1
 \end{aligned}$$

to find $h = \frac{1}{5}$ and $k = \frac{7}{5}$.

Let $x = u + \frac{1}{5}$ and $y = v + \frac{7}{5}$. Then $\frac{dy}{dx} = \frac{dv}{du}$. Substitute these into the differential equation:

$$\begin{aligned}\frac{dy}{dx} &= \frac{x + 2y - 3}{2x - y + 1} \\ \frac{dv}{du} &= \frac{u + 2v}{2u - v} \\ (2u - v) dv &= (u + 2v) du\end{aligned}$$

Both $2u - v$ and $u + 2v$ are homogeneous of degree 1. Let $v = uw$. Then $dv = u dw + w du$. Substitute these into the differential equation.

$$\begin{aligned}(2u - v) dv &= (u + 2v) du \\ (2u - uw)(u dw + w du) &= (u + 2uw) du \\ (-uw^2 - u) du + (2u^2 - u^2w) dw &= 0 \\ -u(w^2 + 1) du + u^2(2 - w) dw &= 0\end{aligned}$$

For $u \neq 0$, we can separate the variables by dividing by u^2 and $w^2 + 1$.

$$\begin{aligned}-u(w^2 + 1) du + u^2(2 - w) dw &= 0 \\ \frac{-u(w^2 + 1)}{-u^2(w^2 + 1)} du + \frac{u^2(2 - w)}{-u^2(w^2 + 1)} dw &= 0 \\ \frac{1}{u} du + \frac{w - 2}{w^2 + 1} dw &= 0\end{aligned}$$

Integrate.

$$\begin{aligned}
 \int \frac{1}{u} du + \int \frac{w-2}{w^2+1} dw &= 0 \\
 \int \frac{1}{u} du + \int \left(\frac{w}{w^2+1} - \frac{2}{w^2+1} \right) dw &= 0 \\
 \ln |u| + \frac{1}{2} \ln(w^2+1) - 2 \tan^{-1} w &= 0 \\
 \ln |u| + \frac{1}{2} \ln \left(\frac{v^2}{u^2} + 1 \right) - 2 \tan^{-1} \left(\frac{v}{u} \right) &= C \quad w = \frac{v}{u} \\
 \ln |u| + \frac{1}{2} \ln \left(\frac{u^2 + v^2}{u^2} \right) - 2 \tan^{-1} \left(\frac{v}{u} \right) &= C \\
 \ln |u| + \frac{1}{2} \ln(u^2 + v^2) - \frac{1}{2} \ln(u^2) - 2 \tan^{-1} \left(\frac{v}{u} \right) &= C \\
 \ln |u| + \frac{1}{2} \ln(u^2 + v^2) - \ln(\sqrt{u^2}) - 2 \tan^{-1} \left(\frac{v}{u} \right) &= C \\
 \ln |u| + \frac{1}{2} \ln(u^2 + v^2) - \ln |u| - 2 \tan^{-1} \left(\frac{v}{u} \right) &= C \\
 \frac{1}{2} \ln(u^2 + v^2) - 2 \tan^{-1} \left(\frac{v}{u} \right) &= C \\
 \frac{1}{2} \ln \left(\left(x - \frac{1}{5} \right)^2 + \left(y - \frac{7}{5} \right)^2 \right) - 2 \tan^{-1} \left(\frac{y - \frac{7}{5}}{x - \frac{1}{5}} \right) &= C \quad u = x - \frac{1}{5}, \quad v = y - \frac{7}{5} \\
 \frac{1}{2} \ln \left(\left(\frac{5x-1}{5} \right)^2 + \left(\frac{5y-7}{2} \right)^2 \right) - 2 \tan^{-1} \left(\frac{5y-7}{5x-1} \right) &= C \\
 \frac{1}{2} \ln \left(\frac{(5x-1)^2}{25} + \frac{(5y-7)^2}{25} \right) - 2 \tan^{-1} \left(\frac{5y-7}{5x-1} \right) &= C \\
 \frac{1}{2} \ln((5x-1)^2 + (5y-7)^2) - \frac{1}{2} \ln 25 - 2 \tan^{-1} \left(\frac{5y-7}{5x-1} \right) &= C \\
 \frac{1}{2} \ln((5x-1)^2 + (5y-7)^2) - \ln \sqrt{25} - 2 \tan^{-1} \left(\frac{5y-7}{5x-1} \right) &= C \\
 \frac{1}{2} \ln((5x-1)^2 + (5y-7)^2) - 2 \tan^{-1} \left(\frac{5y-7}{5x-1} \right) &= C + \ln 5
 \end{aligned}$$

To find the particular solution, substitute $x = 3$ and $y = 4$. The particular solution is

$$\boxed{\frac{1}{2} \ln((5x-1)^2 + (5y-7)^2) - 2 \tan^{-1} \left(\frac{5y-7}{5x-1} \right) = \ln \sqrt{365} - 2 \tan^{-1} \left(\frac{13}{14} \right)}$$

49. Differentiate $y^2 = 4Cx$ with respect to x to get $2yy' = 4C$. Since $C = \frac{y^2}{4x}$ from the original equation, the differential equation becomes

$$\begin{aligned}
 2yy' &= 4C \\
 2yy' &= 4 \frac{y^2}{4x} \\
 y' &= \frac{y}{2x}
 \end{aligned}$$

Replace y' with its opposite reciprocal $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = -\frac{2x}{y}$$

The differential equation is separable and can be written as

$$y \, dy = -2x \, dx$$

The general solution is

$$\frac{1}{2}y^2 = -x^2 + K_1 \quad \text{or} \quad y^2 = -2x^2 + K$$

Note that $2x^2 + y^2 = K$ describes an ellipse when $K > 0$, describes a single point $(0, 0)$ when $K = 0$, and describes no points in the plane when $K < 0$. The orthogonal trajectories for the family of parabolas $y^2 = 4Cx$ is a family of ellipses $\boxed{2x^2 + y^2 = K}$, where $K > 0$.

50. We will find the orthogonal trajectories of all circles tangent to the x -axis at $(0, 0)$, then translate the family.

A line tangent to a circle is perpendicular to the radius at the point of contact. For a circle to be tangent to the x -axis, the radius that meets the x -axis must be vertical. For a circle to be tangent to the x -axis at the origin, the center is of the form $(0, b)$. The family of circles perpendicular to the x -axis at $(0, 0)$ is $x^2 + (y - C)^2 = C^2$, where $C \neq 0$, which can be rewritten as:

$$\begin{aligned} x^2 + (y - C)^2 &= C^2 \\ x^2 + y^2 - 2Cy + C^2 &= C^2 \\ x^2 + y^2 &= 2Cy \\ \frac{x^2 + y^2}{y} &= 2C \end{aligned}$$

Differentiate implicitly with respect to x to find y' .

$$\begin{aligned} \frac{d}{dx} \left(\frac{x^2 + y^2}{y} \right) &= \frac{d}{dx} (2C) \\ \frac{y(2x + 2yy') - (x^2 + y^2)y'}{y^2} &= 0 \\ y(2x + 2yy') - (x^2 + y^2)y' &= 0 \\ 2xy + (y^2 - x^2)y' &= 0 \\ (y^2 - x^2)y' &= -2xy \\ y' &= -\frac{2xy}{y^2 - x^2} \end{aligned}$$

Replace y' with its opposite reciprocal $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = \frac{y^2 - x^2}{2xy}$$

Rewrite in differential form as $(x^2 - y^2) \, dy + 2xy \, dx = 0$. This is a homogenous differential equation. Let $y = xv$. Then $dy = x \, dv + v \, dx$. Substitute these into the differential equation:

$$\begin{aligned} (x^2 - y^2) \, dy + 2xy \, dx &= 0 \\ (x^2 - x^2v^2) \, dx + 2x^2v \, (x \, dv + v \, dx) &= 0 \\ (x^2 + x^2v^2) \, dx + 2x^3v \, dv &= 0 \\ x^2(1 + v^2) \, dx + 2x^3v \, dv &= 0 \end{aligned}$$

For $x \neq 0$, separate the variables by dividing by x^3 and $1 + v^2$, then integrate.

$$\begin{aligned}\frac{1}{x} dx + \frac{2v}{1+v^2} dv &= 0 \\ \int \frac{1}{x} dx + \int \frac{2v}{1+v^2} dv &= 0 \\ \ln|x| + \ln(1+v^2) &= K_1 \\ \ln|x| + \ln\left(1 + \frac{y^2}{x^2}\right) &= K_1 \\ \ln\left|\frac{x^2+y^2}{x}\right| &= K_1 \\ \left|\frac{x^2+y^2}{x}\right| &= e^{K_1} \\ \frac{x^2+y^2}{x} &= \pm e^{K_1}\end{aligned}$$

Since K_1 is a constant, we can write $K = \pm e^{K_1}$, where $K \neq 0$ is a constant. Then the family of orthogonal trajectories to the family of circles tangent to the x -axis at the origin is $x^2 + y^2 = Kx$, where K is a constant.

Translate this family to the right 3 units to find that the orthogonal trajectories of all circles tangent to the x -axis at $(3, 0)$ is the family of circles tangent to the line $x = 3$ at $(3, 0)$, $\boxed{(x-3)^2 + y^2 = K(x-3)}$, where K is a constant.

51. Consider the differential equation

$$\frac{du}{dt} = k(T - u)$$

where k is a positive constant.

- (a) The differential equation is separable, so separate the variables and integrate.

$$\begin{aligned}\frac{du}{dt} &= k(T - u) \\ \frac{1}{T - u} du &= k dt \\ \int \frac{1}{T - u} du &= \int k dt \\ -\ln|T - u| &= kt + C_1 \\ \ln|T - u| &= -kt - C_1 \\ |T - u| &= e^{-kt - C_1} \\ |T - u| &= e^{-kt} e^{-C_1} \\ T - u &= \pm e^{-kt} e^{-C_1}\end{aligned}$$

Since C_1 is a constant, we may write $C = \pm e^{-C_1}$, where $C \neq 0$ is a constant. It can be shown that $C = 0$ also provides a solution, so C is any constant. Then $T - u = Ce^{-kt}$ leads to the general solution of $\boxed{u = T - Ce^{-kt}}$, where C is a constant.

- (b) When $t = 0$, the initial temperature is $u = u_0$. Substitute these into the general solution to find C .

$$\begin{aligned}u &= T - Ce^{-kt} \\ u_0 &= T - Ce^0 \\ u_0 &= T - C \\ C &= T - u_0\end{aligned}$$

The particular solution is $\boxed{u = T - (T - u_0)e^{-kt}}$.

- (c) The initial temperature of the bar is $u_0 = 25$ and the medium temperature is the temperature of the boiling water $T = 100$. The equation that describes the temperature of the bar in degrees Celsius at time t in seconds is

$$u = 100 - 75e^{-kt}$$

When $t = 5$, the temperature is $u = 35$. Substitute these into the equation to find k .

$$\begin{aligned} u &= 100 - 75e^{-kt} \\ 35 &= 100 - 75e^{-5k} \\ -65 &= -75e^{-5k} \\ \frac{13}{15} &= e^{-5k} \\ \ln \frac{13}{15} &= -5k \\ -0.2 \ln \frac{13}{15} &= k \end{aligned}$$

Now the equation that describes the temperature of the bar at time t in seconds is

$$u = 100 - 75e^{0.2t \ln \frac{13}{15}}$$

After one minute, the time is $t = 60$ seconds, which is substituted into the equation to get

$$u = 100 - 75e^{(0.2)(60) \ln \frac{13}{15}} \approx 86.533$$

The temperature of the bar after 1 minute is approximately $\boxed{86.533^\circ\text{C}}$.

- (d) The graph of $u = 100 - 75e^{0.2t \ln \frac{13}{15}}$ is shown.

- (e) It will take approximately $\boxed{175.1 \text{ seconds}}$ for the temperature of the bar to be within 0.5°C of the temperature of the boiling water.

52. The differential equation from Problem 52 applies to this problem,

$$\frac{du}{dt} = k(T - u)$$

and the same general solution applies as well

$$u = T - (T - u_0)e^{-kt}$$

The initial temperature is $u_0 = 1230$ and the surrounding temperature is $T = 30$. Substitute these into the general solution to get

$$u = 30 + 1200e^{-kt}$$

where u is in degrees Celsius and t is in minutes. After 10 minutes, $t = 10$ and the temperature is $u = 1030$. Substitute these into the equation to find k .

$$\begin{aligned} u &= 30 + 1200e^{-kt} \\ 1030 &= 30 + 1200e^{-10k} \\ 1000 &= 1200e^{-10k} \\ \frac{5}{6} &= e^{-10k} \\ \ln \frac{5}{6} &= -10k \\ -0.1 \ln \frac{5}{6} &= k \end{aligned}$$

The function is now

$$u = 30 + 1200e^{0.1t \ln \frac{5}{6}}$$

- (a) Find the time for the bar to cool to 80°C by substituting $u = 80$ into the equation.

$$\begin{aligned} u &= 30 + 1200e^{0.1t \ln \frac{5}{6}} \\ 80 &= 30 + 1200e^{0.1t \ln \frac{5}{6}} \\ 50 &= 1200e^{0.1t \ln \frac{5}{6}} \\ \frac{1}{24} &= e^{0.1t \ln \frac{5}{6}} \\ \ln \frac{1}{24} &= 0.1t \ln \frac{5}{6} \\ \frac{10 \ln \frac{1}{24}}{\ln \frac{5}{6}} &= t \\ 174.310 &\approx t \end{aligned}$$

The bar will cool to 80°C after 174.310 minutes.

- (b) The graph of the temperature of the steel bar over the interval $0 \leq t \leq 240$ is shown.

- (c) The steel bar cools to 50°C after approximately 225 minutes.
53. (a) Since there are no sales initially, use equation (4). Then since the upper limit of sales is \$20 million, the sales at time t are

$$y(t) = 20(1 - e^{-kt})$$

Since sales are \$3 million after 2 years, the boundary condition is $y(2) = 3$. Use the boundary

condition to find the constant k :

$$\begin{aligned} 3 &= 20(1 - e^{-2k}) \\ 0.15 &= 1 - e^{-2k} \\ e^{-2k} &= 0.85 \\ -2k &= \ln 0.85 \\ k &= -0.5 \ln 0.85 \end{aligned}$$

So the function

$$y(t) = 20 \left(1 - e^{(0.5 \ln 0.85)t} \right)$$

models the company's sales in year t .

- (b) According to the model, sales during the eighth year of operations will be $y(8) = 20 \left(1 - e^{(0.5)(8) \ln 0.85} \right) \approx$
9.560 million dollars.
- (c) To find out how long it will take for sales to reach \$12 million, solve the equation $y(t) = 12$ for t .
 Then

$$\begin{aligned} 12 &= 20(1 - e^{0.5t \ln 0.85}) \\ 0.6 &= 1 - e^{0.5t \ln 0.85} \\ e^{0.5t \ln 0.85} &= 0.4 \\ 0.5t \ln 0.85 &= \ln 0.4 \\ t &= \frac{2 \ln 0.4}{\ln 0.85} \approx 11.28 \text{ years} \end{aligned}$$

It will take approximately 11.28 years for annual sales to reach \$12 million.

- (d) The graph of the annual sales of the company for its first 20 years of operation is shown.

54. The bacteria experience inhibited growth, so the function

$$y(t) = M + (R - M)e^{-kt}$$

models the population at time t in hours. The maximum population is $M = 1,000,000$ and the initial population is $R = 1000$. Replacing M and R in the function gives

$$y(t) = 1,000,000 - 999,000e^{-kt}$$

Since the population is 1500 cells after 1 hour, the boundary condition $y(1) = 1500$, which we use to find the constant k :

$$\begin{aligned} 1500 &= 1,000,000 - 999,000e^{-k} \\ 999,000e^{-k} &= 998,500 \\ e^{-k} &= \frac{998,500}{999,000} \\ -k &= \ln \frac{998,500}{999,000} \\ k &= -\ln \frac{998,500}{999,000} \end{aligned}$$

Now the function is

$$y(t) = 1,000,000 - 999,000e^{t \ln \frac{998,500}{999,000}}$$

(a) To find the number of bacteria after 5 hours, find $y(5) = 1,000,000 - 999,000e^{5 \ln \frac{998,500}{999,000}} \approx 3497$. There will be about 3497 bacteria after 5 hours.

(b) To find when the culture contains 9950 bacteria, solve the equation $y(t) = 9950$ for t .

$$\begin{aligned} 9950 &= 1,000,000 - 999,000e^{t \ln \frac{998,500}{999,000}} \\ 999,000e^{t \ln \frac{998,500}{999,000}} &= 990,050 \\ e^{t \ln \frac{998,500}{999,000}} &= \approx 0.991041041 \\ t \ln \frac{998,500}{999,000} &\approx \ln 0.991041041 \approx -0.0089993317 \\ t &\approx 17.976 \end{aligned}$$

The culture will contain 9950 bacteria in approximately 17.976 hours.

55. The growth of the number of words per minute W is inhibited. Since a beginner cannot text at all ($W = 0$), use

$$W(t) = M(1 - e^{-kt})$$

The upper limit on W is 150 words per minute, so $M = 150$. Now the function becomes

$$W(t) = 150(1 - e^{-kt})$$

The condition that the beginner can text 30 words per minute after 10 hours of practice is $W(10) = 30$. Use this condition to find the constant k :

$$\begin{aligned} 30 &= 150(1 - e^{-10k}) \\ 0.2 &= 1 - e^{-10k} \\ e^{-10k} &= 0.8 \\ -10k &= \ln 0.8 \\ k &= -0.1 \ln 0.8 \end{aligned}$$

The function

$$W(t) = 150(1 - e^{0.1t \ln 0.8})$$

models the number of words per minute that the beginner can text after t hours of practice.

- (a) To find the number of words per minute he can text after 25 hours of practice, let $t = 25$, then $W(25) = 150(1 - e^{(0.1)(25) \ln 0.8}) \approx 64.135$. After 25 hours of practice, the beginner can text approximately 64.1 words per minute.

- (b) To find the number of hours of practice required, solve the equation $W(t) = 100$ for t .

$$\begin{aligned}
 100 &= 150(1 - e^{0.1t \ln 0.8}) \\
 \frac{2}{3} &= 1 - e^{0.1t \ln 0.8} \\
 e^{0.1t \ln 0.8} &= \frac{1}{3} \\
 0.1t \ln 0.8 &= \ln \frac{1}{3} \\
 t &= \frac{10 \ln \frac{1}{3}}{\ln 0.8} \approx 49.233
 \end{aligned}$$

It will take approximately 49.2 hours for a beginner to text 100 words per minute.

- (c) The graph of the number of words per minute W a beginner can text as a function of hours of practice is shown.

56. (a) Let $k > 0$ be the constant of proportionality referred to in the problem. Then the rate of change depends on the addition of the drug at a rate of r mg/s and the removal of the drug at a rate of ky mg/s. A differential equation that models the problem is $\frac{dy}{dt} = r - ky$.

- (b) The differential equation is separable and can be written and solved as

$$\begin{aligned}
 \frac{dy}{dt} &= r - ky \\
 \frac{dy}{r - ky} &= dt \\
 \int \frac{dy}{r - ky} &= \int dt \\
 -\frac{1}{k} \ln |r - ky| &= t + C_1 \\
 \ln |r - ky| &= -kt - kC_1 \\
 |r - ky| &= e^{-kt - kC_1} \\
 |r - ky| &= e^{-kt} e^{-kC_1} \\
 r - ky &= \pm e^{-kt} e^{-kC_1} \\
 -ky &= -r \pm e^{-kt} e^{-kC_1} \\
 y &= \frac{r}{k} \pm \frac{e^{-kt} e^{-kC_1}}{k}
 \end{aligned}$$

Since k and C_1 are constants, we let $C = \pm \frac{e^{-kC_1}}{k}$ and the general solution can be written as

$$\boxed{y = \frac{r}{k} + Ce^{-kt}}, \text{ where } k > 0 \text{ and } C \text{ are constants.}$$

- (c) Using the initial condition $y(0) = 0$, $0 = \frac{r}{k} + Ce^0$ so $C = -\frac{r}{k}$. The particular solution is

$$\boxed{y = \frac{r}{k} - \frac{r}{k}e^{-kt}}, \text{ where } k > 0 \text{ is a constant.}$$

57. The frictional force f of an object sliding over a surface is modeled by $f = -Av$, where A is a positive constant.

- (a) Since acceleration is the derivative of velocity, $a = \frac{dv}{dt}$, we can write Newton's Second Law $F = ma$ as

$$F = m \frac{dv}{dt}$$

When the force is due to friction, that is $F = f$, we have the differential equation

$$\boxed{m \frac{dv}{dt} = -Av}$$

where m is the mass of the object and A is a positive constant.

- (b) The differential equation $m \frac{dv}{dt} = -Av$ is separable. Separate the variables and integrate.

$$\begin{aligned} m \frac{dv}{dt} &= -Av \\ m \frac{1}{v} dv &= -A dt \\ m \int \frac{1}{v} dv &= -A \int dt \\ m \ln |v| &= -At + C_1 \\ \ln |v| &= -\frac{A}{m}t + \frac{C_1}{m} \\ |v| &= e^{(-\frac{A}{m}t + \frac{C_1}{m})} \\ |v| &= e^{-\frac{A}{m}t} e^{\frac{C_1}{m}} \\ v &= \pm e^{-\frac{A}{m}t} e^{\frac{C_1}{m}} \end{aligned}$$

Since C_1 and m are constants, we may write $C = \pm e^{\frac{C_1}{m}}$, where $C \neq 0$ is a constant. The speed function is now $v = Ce^{-\frac{A}{m}t}$. Given the initial velocity of v_0 , we have the boundary condition $v(0) = v_0$, and the speed of the object is

$$\boxed{v = v_0 e^{-\frac{A}{m}t}}$$

where A and m are constants.

- (c) The frictional force of a 25-kg sled with a speed of 10 m/s is 150N. The force is negative because the direction of the frictional force is opposite to the direction of the velocity, so $f = -150\text{N} = -150\text{kg} \frac{\text{m}}{\text{s}^2}$ and $v = 10 \frac{\text{m}}{\text{s}}$. Use $f = -Av$ to find A : $-150\text{kg} \frac{\text{m}}{\text{s}^2} = -A \left(10 \frac{\text{m}}{\text{s}}\right)$ so $\boxed{A = 15 \frac{\text{kg}}{\text{s}}}$.
- (d) To find the time required for the sled to slow down to 10% of its initial speed, we solve $v(t) = 0.1v_0$ for t , using $A = 15$ and $m = 25$:

$$\begin{aligned} 0.1v_0 &= v_0 e^{-\frac{15}{25}t} \\ 0.1 &= e^{-0.6t} \\ \ln 0.1 &= -0.6t \\ t &= -\frac{\ln 0.1}{0.6} \approx 3.838 \end{aligned}$$

The sled will down to 10% of its initial speed in approximately 3.838 seconds.

- (e) To slow down to 1.0 m/s, or 10% of the initial speed, takes 3.838 seconds. The distance traveled is the definite integral of the speed. Find the definite integral of $v = 10e^{-0.6t}$ over the interval $[0, 3.838]$.

$$\begin{aligned}\int_0^{3.838} v \, dt &= \int_0^{3.838} 10e^{-0.6t} \, dt \\ &= -\frac{10}{0.6} e^{-0.6t} \Big|_0^{3.838} \\ &\approx 15.0\end{aligned}$$

The sled will travel 15 meters while slowing down to 1.0 m/s.

58. The frictional force f of an object sliding over a surface is modeled by $f = -B\sqrt{v}$, where B is a positive constant.

- (a) Since acceleration is the derivative of velocity, $a = \frac{dv}{dt}$, we can write Newton's Second Law $F = ma$ as

$$F = m \frac{dv}{dt}$$

When the force is due to friction, that is $F = f$, we have the differential equation

$$\boxed{m \frac{dv}{dt} = -B\sqrt{v}}$$

where m is the mass of the object and B is a positive constant.

- (b) The differential equation $m \frac{dv}{dt} = -B\sqrt{v}$ is separable. Separate the variables and integrate.

$$\begin{aligned}m \frac{dv}{dt} &= -B\sqrt{v} \\ mv^{-1/2} dv &= -B \, dt \\ m \int v^{-1/2} dv &= -B \int dt \\ 2mv^{1/2} &= -Bt + C \\ v^{1/2} &= \frac{-Bt + C}{2m} \\ v &= \frac{(C - Bt)^2}{4m^2}\end{aligned}$$

The velocity function is $v = \frac{(C - Bt)^2}{4m^2}$. Solve for C using the initial velocity $v(0) = v_0 = \frac{C^2}{4m^2}$ so $C = 2m\sqrt{v_0}$. The speed of the object is

$$\boxed{v = \frac{(2m\sqrt{v_0} - Bt)^2}{4m^2}}$$

where B and m are constants and $0 \leq t \leq \frac{2m}{B}\sqrt{v_0}$.

- (c) The frictional force of a 25-kg sled with a speed of 10 m/s is 150N. The force is negative because the direction of the frictional force is opposite to the direction of the velocity, so $f = -150$ and $v = 10$. Use $f = -B\sqrt{v}$ to find B :

$$\begin{aligned}-150 &= -B\sqrt{10} \\ \frac{150}{\sqrt{10}} &= B \\ \frac{150\sqrt{10}}{10} &= B \\ 15\sqrt{10} &= B\end{aligned}$$

Therefore

$$\boxed{B = 15\sqrt{10}}$$

- (d) Using $B = 15\sqrt{10}$ and $m = 25$, the speed is $v = \frac{(50\sqrt{v_0} - 15t\sqrt{10})^2}{2500}$, where $0 \leq t \leq \frac{\sqrt{10v_0}}{3}$. To find the time required for the sled to slow down to 10% of its initial speed, we solve $v(t) = 0.1v_0$ for t :

$$\begin{aligned} 0.1v_0 &= \frac{(50\sqrt{v_0} - 15t\sqrt{10})^2}{2500} \\ 250v_0 &= (50\sqrt{v_0} - 15t\sqrt{10})^2 \\ \pm\sqrt{250}\sqrt{v_0} &= 50\sqrt{v_0} - 15t\sqrt{10} \\ 15t\sqrt{10} &= 50\sqrt{v_0} \pm \sqrt{250}\sqrt{v_0} \\ t &= \frac{50 \pm \sqrt{250}}{15\sqrt{10}}\sqrt{v_0} \end{aligned}$$

Only $t = \frac{50 - \sqrt{250}}{15\sqrt{10}}\sqrt{v_0} \leq \frac{\sqrt{10v_0}}{3}$, so the sled will down to 10% of its initial speed in approximately $\boxed{0.721\sqrt{v_0} \text{ seconds}}$.

- (e) To slow down to 1.0 m/s, or 10% of the initial speed, takes $0.721\sqrt{10} \approx 2.279$ seconds. The distance traveled is the definite integral of the speed. Find the definite integral of $v = \frac{(50\sqrt{10} - 15t)^2}{2500}$ over the interval $[0, 2.279]$.

$$\begin{aligned} \int_0^{2.279} v \, dt &= \int_0^{2.279} \frac{(50\sqrt{10} - 15t\sqrt{10})^2}{2500} \, dt \\ &= \frac{1}{3} \left(-\frac{1}{15\sqrt{10}} \right) \frac{(50\sqrt{10} - 15t)^3}{2500} \bigg|_0^{2.279} \\ &\approx 10.760 \end{aligned}$$

The sled will travel $\boxed{10.760 \text{ meters}}$ while slowing down to 1.0 m/s.

59. Consider a circuit with initial charge q_0 that satisfies the differential equation

$$\frac{dq}{dt} + \frac{q}{RC} = 0$$

- (a) The differential equation is separable and can be written in the differential form

$$\frac{1}{q} dq + \frac{1}{RC} dt = 0$$

Integrate and solve for q .

$$\begin{aligned} \int \frac{1}{q} dq + \frac{1}{RC} \int dt &= 0 \\ \ln |q| + \frac{1}{RC} t &= K_1 \\ \ln |q| &= K_1 - \frac{1}{RC} t \\ |q| &= e^{(K_1 - \frac{1}{RC} t)} \\ |q| &= e^{K_1} e^{-\frac{1}{RC} t} \\ q &= \pm e^{K_1} e^{-\frac{1}{RC} t} \end{aligned}$$

Since K_1 is a constant, we may write $K = \pm e^{K_1}$, where K is a constant. The charge is now $q = Ke^{-\frac{1}{RC}t}$. Using the initial charge is $q(0) = q_0$, we can solve for K : $q_0 = Ke^0$ so $K = q_0$. The charge of the capacitor is given by the function

$$q = q_0 e^{-\frac{1}{RC}t}$$

- (b) Using $R = 150$ and $C = 0.000005$ (a microfarad is one-millionth of a farad), the charge is given by the function

$$q = q_0 e^{-\frac{4000}{3}t}$$

For the capacitor to lose 99% of its charge means that the capacitor has only 1% of the initial charge left, so solve $q(t) = 0.01q_0$ for t .

$$\begin{aligned} 0.01q_0 &= q_0 e^{-\frac{4000}{3}t} \\ 0.01 &= e^{-\frac{4000}{3}t} \\ \ln 0.01 &= -\frac{4000}{3}t \\ t &= -\frac{3}{4000} \ln 0.01 \approx 0.00345 \end{aligned}$$

The discharging capacitor will lose 99% of its initial charge in approximately 0.00345 seconds.

60. Model the air resistance with

$$F_{\text{drag}} = -Av^2$$

where A is a positive constant.

- (a) Since acceleration is the derivative of velocity, $a = \frac{dv}{dt}$, we can write Newton's Second Law $F = ma$ as

$$F = m \frac{dv}{dt}$$

When the only force is drag, that is $F = F_{\text{drag}}$, we have the differential equation

$$m \frac{dv}{dt} = -Av^2$$

where A is a positive constant.

- (b) The differential equation $m \frac{dv}{dt} = -Av^2$ is separable. Separate the variables and integrate.

$$\begin{aligned} m \frac{dv}{dt} &= -Av^2 \\ mv^{-2} dv &= -A dt \\ m \int v^{-2} dv &= -A \int dt \\ -mv^{-1} &= -At + C \\ v^{-1} &= \frac{At - C}{m} \\ v &= \frac{m}{At - C} \end{aligned}$$

The velocity of the object is modeled by the function

$$v = \frac{m}{At - C}$$

where A is a positive constant and C is a constant.

(c) The limit of $v(t)$ as t approaches infinity is

$$\lim_{t \rightarrow \infty} \frac{m}{At - C} = 0$$

If the model for air resistance at high speeds is used for arbitrarily large values of t , then the speed of the projectile approaches zero.

Challenge Problems

61. Given the family of hyperbolas

$$\frac{x^2}{C^2} - \frac{y^2}{4 - C^2} = 1$$

where $0 < C < 2$, first clear the denominators and then find y' using implicit differentiation.

$$\begin{aligned} \frac{x^2}{C^2} - \frac{y^2}{4 - C^2} &= 1 \\ \frac{x^2}{C^2} \cdot C^2(4 - C^2) - \frac{y^2}{4 - C^2} \cdot C^2(4 - C^2) &= 1 \cdot C^2(4 - C^2) \\ (4 - C^2)x^2 - C^2y^2 &= C^2(4 - C^2) \\ (4 - C^2)(2x) - C^2(2yy') &= 0 \\ (4 - C^2)x - C^2yy' &= 0 \end{aligned}$$

It is necessary to find the derivative y' in terms of x and y alone, without using the constant C . To do this, first solve for $4 - C^2$ above.

$$\begin{aligned} (4 - C^2)x - C^2yy' &= 0 \\ (4 - C^2)x &= C^2yy' \\ 4 - C^2 &= \frac{C^2yy'}{x} \end{aligned}$$

Now replace $4 - C^2$ in the original equation, and solve for C^2 .

$$\begin{aligned} \frac{x^2}{C^2} - \frac{y^2}{4 - C^2} &= 1 \\ \frac{x^2}{C^2} - \frac{y^2}{\frac{C^2yy'}{x}} &= 1 \\ \frac{x^2}{C^2} - \frac{xy^2}{C^2yy'} &= 1 \\ \frac{x^2}{C^2} - \frac{xy}{C^2y'} &= 1 \\ x^2 - \frac{xy}{y'} &= C^2 \end{aligned}$$

Now replace C^2 in the differential equation found before.

$$\begin{aligned} (4 - C^2)x - C^2yy' &= 0 \\ \left(4 - \left(x^2 - \frac{xy}{y'}\right)\right)x - \left(x^2 - \frac{xy}{y'}\right)yy' &= 0 \\ 4x - x^3 + \frac{x^2y}{y'} - x^2yy' + xy^2 &= 0 \\ 4 - x^2 + \frac{xy}{y'} - xy y' + y^2 &= 0 \end{aligned}$$

We find the differential equation for the family of orthogonal curves by replacing y' in the differential equation with $-\frac{1}{y'}$.

$$\begin{aligned} 4 - x^2 + \frac{xy}{y'} - xy y' + y^2 &= 0 \\ 4 - x^2 + \frac{xy}{-\frac{1}{y'}} - xy \left(-\frac{1}{y'}\right) + y^2 &= 0 \\ 4 - x^2 - xy y' + \frac{xy}{y'} + y^2 &= 0 \end{aligned}$$

The differential equation for the family of orthogonal trajectories is the same as the differential equation for the original family, so the solutions are of the form

$$\frac{x^2}{C^2} - \frac{y^2}{4 - C^2} = 1$$

as well. The orthogonal trajectories consists of the family of ellipses

$$\boxed{\frac{x^2}{C^2} - \frac{y^2}{4 - C^2} = 1}$$

where $C > 2$. The hyperbolas and ellipses all have $(\pm 2, 0)$ as foci.

62. The family of parabolas with a common vertex at $(1, 2)$ and having a vertical axis is

$$y - 2 = C(x - 1)^2$$

Rewrite $y - 2 = C(x - 1)^2$ in the form $\frac{y - 2}{(x - 1)^2} = C$. Find y' by differentiating $\frac{y - 2}{(x - 1)^2} = C$ with respect to x .

$$\begin{aligned} \frac{(x - 1)^2 y' - (y - 2) \cdot 2(x - 1)}{(x - 1)^4} &= 0 \\ (x - 1)^2 y' - 2(x - 1)(y - 2) &= 0 \\ (x - 1)^2 y' &= 2(x - 1)(y - 2) \\ y' &= \frac{2(y - 2)}{(x - 1)} \end{aligned}$$

Replace y' with $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = -\frac{(x - 1)}{2(y - 2)}$$

The differential equation $\frac{dy}{dx} = -\frac{x - 1}{2(y - 2)}$ is separable and can be written as

$$2(y - 2) dy = -(x - 1) dx$$

Integrate to find the general solution.

$$\begin{aligned} \int 2(y - 2) dy &= -\int (x - 1) dx \\ (y - 2)^2 &= -\frac{1}{2}(x - 1)^2 + K \end{aligned}$$

The orthogonal trajectories for the family of curves $y = Cx^2$ is the family $\boxed{\frac{1}{2}(x-1)^2 + (y-2)^2 = K}$.

To find the particular curves needed for the graph, substitute $x = 2$ and $y = 3$ into $y - 2 = C(x - 1)^2$ and $\frac{1}{2}(x - 1)^2 + (y - 2)^2 = K$ separately and solve for C and K . The graph of $y - 2 = (x - 1)^2$ and $(x - 1)^2 + 2(y - 2)^2 = 3$ is shown.

63. (a) Recall Newton's Second Law $F = ma$ and set it equal to the force due to gravity $F = \frac{k}{x^2}$:

$$ma = \frac{k}{x^2}$$

Let g be the magnitude of acceleration due to gravity at sea level, that is when $x = R$. Solve for k by substituting $a = -g$ and $x = R$ into the equation: $-mg = \frac{k}{R^2}$ so $k = -mgR^2$. The equation becomes $ma = -\frac{mgR^2}{x^2}$ or

$$a = -\frac{R^2g}{x^2}$$

Also consider that $a = \frac{dv}{dt} = \frac{dv}{dx} \frac{dx}{dt} = v \frac{dv}{dx}$. The equation now becomes the differential equation

$$v \frac{dv}{dx} = -\frac{R^2g}{x^2}$$

The differential equation is separable, so separate the variables and integrate.

$$\begin{aligned} v dv &= -R^2g x^{-2} dx \\ \int v dv &= -R^2g \int x^{-2} dx \\ \frac{1}{2}v^2 &= \frac{R^2g}{x} + C \end{aligned}$$

where C is a constant. The initial velocity is v_0 when $x = R$. Solve for C by making the substitutions $v = v_0$ and $x = R$:

$$\begin{aligned} \frac{1}{2}v^2 &= \frac{R^2g}{x} + C \\ \frac{1}{2}v_0^2 &= \frac{R^2g}{R} + C \\ \frac{1}{2}v_0^2 &= Rg + C \\ \frac{1}{2}v_0^2 - Rg &= C \end{aligned}$$

Replacing C gives $\frac{1}{2}v^2 = \frac{1}{2}v_0^2 - Rg + \frac{R^2g}{x}$. The velocity of the projectile is given by

$$v^2 = v_0^2 - 2Rg + \frac{2R^2g}{x}$$

- (b) To keep the projectile going indefinitely, $f(x) = v_0^2 - 2Rg + \frac{2R^2g}{x} > 0$ for all $x > R$. Notice that f is a decreasing function with respect to x because

$$f'(x) = -\frac{2R^2g}{x^2} < 0$$

for $x > R$. To keep the projectile going indefinitely, it is enough then for the limit as x approaches infinity to be greater than or equal to zero. If

$$\lim_{x \rightarrow \infty} \left(v_0^2 - 2Rg + \frac{2R^2g}{x} \right) = v_0^2 - 2Rg \geq 0$$

then $v_0 \geq \sqrt{2Rg}$. The smallest value of v_0 is the escape velocity $\boxed{\sqrt{2Rg}}$.

64. The volume of water is a function of time, $V(t) = \pi r^2 h$. The radius of the cylinder remains constant $r = \frac{3}{2}$, but the height of the water is also a function of time, $h = h(t)$, so $V(t) = \frac{9\pi}{4}h(t)$. Differentiate to find

$$\frac{dV}{dt} = \frac{9\pi}{4} \frac{dh}{dt}$$

The circular hole has area $A = \pi \left(\frac{1}{2}\right)^2 = \frac{\pi}{4}$, and we are given $k = 0.6$ and $g = 32$. The equation $\frac{dV}{dt} = -kA\sqrt{2gh}$ becomes

$$\frac{dV}{dt} = -(0.6)\frac{\pi}{4}\sqrt{2(32)}h^{1/2} = -\frac{6\pi}{5}h^{1/2}$$

- (a) Set these equations equal to each other to get

$$\frac{9\pi}{4} \frac{dh}{dt} = -\frac{6\pi}{5}h^{1/2}$$

This differential equation is separable, so separate the variables and integrate.

$$\begin{aligned} \frac{9\pi}{4} \frac{dh}{dt} &= -\frac{6\pi}{5}h^{1/2} \\ h^{-1/2} dh &= -\frac{8}{15} dt \\ \int h^{-1/2} dh &= -\frac{8}{15} \int dt \\ 2h^{1/2} &= -\frac{8}{15}t + C_1 \\ h^{1/2} &= -\frac{4}{15}t + \frac{C_1}{2} \end{aligned}$$

Since C_1 is a constant, we may write $C = \frac{C_1}{2}$ where C is a constant. The equation is

$$h^{1/2} = -\frac{4}{15}t + C$$

The initial height of the water is $h(0) = 6$. Use the boundary condition to find C : $6^{1/2} = \sqrt{6} = C$. Then the height of the water is

$$\boxed{h = \left(-\frac{4}{15}t + \sqrt{6}\right)^2}$$

at time t in seconds.

(b) To find the time required to empty the tank, solve the equation $h(t) = 0$ for t :

$$\begin{aligned} 0 &= \left(-\frac{4}{15}t + \sqrt{6}\right)^2 \\ 0 &= -\frac{4}{15}t + \sqrt{6} \\ \frac{4}{15}t &= \sqrt{6} \\ t &= \frac{15\sqrt{6}}{4} \approx 9.186 \end{aligned}$$

The tank will drain in approximately 9.186 seconds.

65. The volume of water is $V(t) = \pi r^2 h(t)$, where $V(t)$ is a function of t , r is the constant radius of the cylinder, and $h(t)$ is the height of the water which is also a function of t . The rate of flow is the derivative of the volume and is proportional to the square root of the height of the water:

$$\frac{dV}{dt} = \pi r^2 \frac{dh}{dt} = -k\sqrt{h}$$

where k is a positive constant and r is the constant radius. This differential equation is separable, so separate the variables and integrate.

$$\begin{aligned} \pi r^2 \frac{dh}{dt} &= -k h^{1/2} \\ \pi r^2 h^{-1/2} dh &= -k dt \\ \pi r^2 \int h^{-1/2} dh &= -k \int dt \\ 2\pi r^2 h^{1/2} &= -kt + C \end{aligned}$$

Denote the initial height h_0 . Use the initial height to find C : $2\pi r^2 \sqrt{h_0} = C$. So we can write

$$2\pi r^2 h^{1/2} = -kt + 2\pi r^2 \sqrt{h_0}$$

To find the time required to leak three-fourths of the water (when the volume is one-fourth of the original volume), solve the equation when $h = \frac{1}{4}h_0$ for t :

$$\begin{aligned} 2\pi r^2 \sqrt{\frac{1}{4}h_0} &= -kt + 2\pi r^2 \sqrt{h_0} \\ \pi r^2 \sqrt{h_0} &= -kt + 2\pi r^2 \sqrt{h_0} \\ kt &= \pi r^2 \sqrt{h_0} \\ t &= \frac{\pi r^2 \sqrt{h_0}}{k} \end{aligned}$$

The time required to leak three-fourths of the water is $\frac{\pi r^2 \sqrt{h_0}}{k}$. To find the time required to empty the tank completely, solve the equation when $h = 0$ for t :

$$\begin{aligned} 0 &= -kt + 2\pi r^2 \sqrt{h_0} \\ kt &= 2\pi r^2 \sqrt{h_0} \\ t &= \frac{2\pi r^2 \sqrt{h_0}}{k} \end{aligned}$$

The time required to empty the entire tank is $\frac{2\pi r^2 \sqrt{h_0}}{k}$, twice as long as the time required to leak three-fourths of the water. Therefore, the time required to leak out three-fourths of the water is equal to the time required to leak out the remaining one-fourth of the water.

66. Let r denote the radius of the tank, and let $y(t)$ denote the depth and $V(t)$ the volume of the water at time t in hours. Pressure is proportional to the water depth, so the rate of change of volume is proportional to the water depth:

$$\frac{dV}{dt} = k_1 y$$

Differentiating $V = \pi r^2 y$ with respect to t yields

$$\begin{aligned}\frac{dV}{dt} &= \pi r^2 \frac{dy}{dt} \\ k_1 y &= \pi r^2 \frac{dy}{dt} \\ \frac{k_1}{\pi r^2} y &= \frac{dy}{dt} \\ ky &= \frac{dy}{dt}\end{aligned}$$

where $k = \frac{k_1}{\pi r^2}$. This is a separable equation with a general solution of $y = y_0 e^{kt}$. The tank loses 2% of its water in 24 h, so the depth of the water is 98% of the original in 24 h, $y(24) = 0.98y_0$.

$$\begin{aligned}0.98y_0 &= y_0 e^{24k} \\ 0.98 &= e^{24k} \\ \ln(0.98) &= 24k \\ \frac{\ln(0.98)}{24} &= k\end{aligned}$$

Now solve for the t such that $y(t) = 0.5y_0$,

$$\begin{aligned}0.5y_0 &= y_0 e^{t \ln(0.98)/24} \\ 0.5 &= e^{t \ln(0.98)/24} \\ \ln(0.5) &= \frac{t \ln(0.98)}{24} \\ \frac{24 \ln(0.5)}{\ln(0.98)} &= t \\ 823.431 &\approx t\end{aligned}$$

The tank will be half empty in $\boxed{\frac{24 \ln(0.5)}{\ln(0.98)} \approx 823.431}$ hours.

16.3 Exact Differential Equations

Concepts and Vocabulary

1. True. Let $M = xy$ and $N = \frac{x^2}{2}$. Then

$$\frac{\partial M}{\partial y} = x \quad \text{and} \quad \frac{\partial N}{\partial x} = x$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , then differential equation $xy \, dx + \frac{x^2}{2} \, dy = 0$ is exact.

2. False. Let $M = y \cos x$ and $N = -\sin x$. Then

$$\frac{\partial M}{\partial y} = \cos x \quad \text{and} \quad \frac{\partial N}{\partial x} = -\cos x$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$ for all x and y , then differential equation $y \cos x \, dx - \sin x \, dy = 0$ is not exact.

3. False. If $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then $M(x, y) dx + N(x, y) dy = 0$ is an exact differential equation.
4. If the differential equation $M(x, y) dx + N(x, y) dy = 0$ is not exact, but $a(x, y)M(x, y) dx + a(x, y)N(x, y) dy = 0$ is an exact differential equation, then the expression $a(x, y)$ is called an integrating factor.

Skill Building

5. Consider the differential equation $(4x - 2y + 5) dx + (2y - 2x) dy = 0$.

(a) Let $M = 4x - 2y + 5$ and $N = 2y - 2x$. Then

$$\frac{\partial M}{\partial y} = -2 \quad \text{and} \quad \frac{\partial N}{\partial x} = -2$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M = 4x - 2y + 5$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (4x - 2y + 5) dx = 2x^2 - 2xy + 5x + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [2x^2 - 2xy + 5x + B(y)] = -2x + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ -2x + \frac{\partial B}{\partial y} &= 2y - 2x \\ \frac{\partial B}{\partial y} &= 2y \end{aligned}$$

Now we integrate $\frac{dB}{dy} = 2y$ with respect to y .

$$B(y) = \int 2y dy = y^2 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = 2x^2 - 2xy + 5x + y^2 + C$$

The general solution of the differential equation is

$$\boxed{2x^2 - 2xy + 5x + y^2 + C = 0}$$

where C is a constant.

6. Consider the differential equation $(3x^2 + 3xy^2) dx + (3x^2y - 3y^2 + 2y) dy = 0$.

(a) Let $M = 3x^2 + 3xy^2$ and $N = 3x^2y - 3y^2 + 2y$. Then

$$\frac{\partial M}{\partial y} = 6xy \quad \text{and} \quad \frac{\partial N}{\partial x} = 6xy$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M = 3x^2 + 3xy^2$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (3x^2 + 3xy^2) dx = x^3 + \frac{3}{2}x^2y^2 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[x^3 + \frac{3}{2}x^2y^2 + B(y) \right] = 3x^2y + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 3x^2y + \frac{\partial B}{\partial y} &= 3x^2y - 3y^2 + 2y \\ \frac{\partial B}{\partial y} &= -3y^2 + 2y \end{aligned}$$

Now we integrate $\frac{dB}{dy} = -3y^2 + 2y$ with respect to y .

$$B(y) = \int (-3y^2 + 2y) dy = -y^3 + y^2 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = x^3 + \frac{3}{2}x^2y^2 - y^3 + y^2 + C$$

The general solution of the differential equation is

$$\boxed{x^3 + \frac{3}{2}x^2y^2 - y^3 + y^2 + C = 0}$$

where C is a constant.

7. Consider the differential equation $(a^2 - 2xy - y^2) dx - (x + y)^2 dy = 0$, where a is a constant.

- (a) Let $M = a^2 - 2xy - y^2$ and $N = -(x + y)^2$. Then

$$\frac{\partial M}{\partial y} = -2x - 2y \quad \text{and} \quad \frac{\partial N}{\partial x} = -2x - 2y$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M = a^2 - 2xy - y^2$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (a^2 - 2xy - y^2) dx = a^2x - x^2y - xy^2 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [a^2x - x^2y - xy^2 + B(y)] = -x^2 - 2xy + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ -x^2 - 2xy + \frac{\partial B}{\partial y} &= -(x+y)^2 \\ -x^2 - 2xy + \frac{\partial B}{\partial y} &= -x^2 - 2xy - y^2 \\ \frac{\partial B}{\partial y} &= -y^2\end{aligned}$$

Now we integrate $\frac{dB}{dy} = -y^2$ with respect to y .

$$B(y) = -\int y^2 dy = -\frac{1}{3}y^3 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = a^2x - x^2y - xy^2 - \frac{1}{3}y^3 + C$$

The general solution of the differential equation is

$$a^2x - x^2y - xy^2 - \frac{1}{3}y^3 + C = 0$$

where C is a constant.

8. Consider the differential equation $(2ax + by + g)dx + (2e^y + bx + h)dy = 0$, where a, b, g, h are constants.

(a) Let $M = 2ax + by + g$ and $N = 2e^y + bx + h$. Then

$$\frac{\partial M}{\partial y} = b \quad \text{and} \quad \frac{\partial N}{\partial x} = b$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M = 2ax + by + g$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (2ax + by + g) dx = ax^2 + bxy + gx + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [ax^2 + bxy + gx + B(y)] = bx + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ bx + \frac{\partial B}{\partial y} &= 2e^y + bx + h \\ \frac{\partial B}{\partial y} &= 2e^y + h\end{aligned}$$

Now we integrate $\frac{dB}{dy} = 2e^y + h$ with respect to y .

$$B(y) = \int (2e^y + h) dy = 2e^y + hy + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = ax^2 + bxy + gx + 2e^y + hy + C$$

The general solution of the differential equation is

$$\boxed{ax^2 + bxy + gx + 2e^y + hy + C = 0}$$

where C is a constant.

9. Consider the differential equation $\frac{1}{y} dx - \frac{x}{y^2} dy = 0$.

(a) Let $M = \frac{1}{y}$ and $N = -\frac{x}{y^2}$. Then

$$\frac{\partial M}{\partial y} = -\frac{1}{y^2} \quad \text{and} \quad \frac{\partial N}{\partial x} = -\frac{1}{y^2}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and $y \neq 0$, the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = \frac{1}{y}$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \frac{1}{y} dx = \frac{x}{y} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[\frac{x}{y} + B(y) \right] = -\frac{x}{y^2} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ -\frac{x}{y^2} + \frac{\partial B}{\partial y} &= -\frac{x}{y^2} \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = \frac{x}{y} + C$$

The general solution of the differential equation is

$$\boxed{\frac{x}{y} + C = 0}$$

where C is a constant.

10. Consider the differential equation $\frac{y}{x^2} dx - \frac{1}{x} dy = 0$.

(a) Let $M = \frac{y}{x^2}$ and $N = -\frac{1}{x}$. Then

$$\frac{\partial M}{\partial y} = \frac{1}{x^2} \quad \text{and} \quad \frac{\partial N}{\partial x} = \frac{1}{x^2}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all $x \neq 0$ and y , the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = \frac{y}{x^2}$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \frac{y}{x^2} dx = -\frac{y}{x} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[-\frac{y}{x} + B(y) \right] = -\frac{1}{x} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ -\frac{1}{x} + \frac{\partial B}{\partial y} &= -\frac{1}{x} \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = -\frac{y}{x} + C$$

The general solution of the differential equation is

$$\boxed{-\frac{y}{x} + C = 0}$$

where C is a constant.

11. Consider the differential equation $(x-1)^{-1}y dx + [\ln(2x-2) + y^{-1}] dy = 0$.

(a) Let $M = (x-1)^{-1}y$ and $N = \ln(2x-2) + y^{-1}$. Then

$$\frac{\partial M}{\partial y} = (x-1)^{-1} \quad \text{and} \quad \frac{\partial N}{\partial x} = \frac{2}{2x-2} = \frac{1}{x-1}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all $x > 1$ and $y \neq 0$, the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = (x-1)^{-1}y$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (x-1)^{-1}y dx = y \int \frac{1}{x-1} dx = y \ln(x-1) + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [y \ln(x-1) + B(y)] = \ln(x-1) + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ \ln(x-1) + \frac{\partial B}{\partial y} &= \ln(2x-2) + y^{-1} \\ \ln(x-1) + \frac{\partial B}{\partial y} &= \ln(2(x-1)) + y^{-1} \\ \ln(x-1) + \frac{\partial B}{\partial y} &= \ln(2) + \ln(x-1) + y^{-1} \\ \frac{\partial B}{\partial y} &= \ln 2 + y^{-1} \end{aligned}$$

Now we integrate $\frac{dB}{dy} = \ln(2) + y^{-1}$ with respect to y .

$$B(y) = \int (\ln(2) + y^{-1}) dy = y \ln(2) + \ln |y| + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = y \ln(x-1) + y \ln(2) + \ln |y| + C$$

The general solution of the differential equation is

$$\boxed{y \ln(x-1) + y \ln(2) + \ln |y| + C = 0}$$

where C is a constant.

12. Consider the differential equation $(2 \ln(5y) + x^{-1}) dx + 2xy^{-1} dy = 0$.

(a) Let $M = 2 \ln(5y) + x^{-1}$ and $N = 2xy^{-1}$. Then

$$\frac{\partial M}{\partial y} = 2 \frac{5}{5y} = \frac{2}{y} \quad \text{and} \quad \frac{\partial N}{\partial x} = 2y^{-1}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all $x \neq 0$ and $y > 0$, the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = 2 \ln(5y) + x^{-1}$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (2 \ln(5y) + x^{-1}) dx = 2x \ln(5y) + \ln |x| + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [2x \ln(5y) + \ln |x| + B(y)] = \frac{2x}{y} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ \frac{2x}{y} + \frac{\partial B}{\partial y} &= 2xy^{-1} \\ \frac{\partial B}{\partial y} &= 0\end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = 2x \ln(5y) + \ln|x| + C$$

The general solution of the differential equation is

$$\boxed{2x \ln(5y) + \ln|x| + C = 0}$$

where C is a constant.

13. Consider the differential equation $(x+3)^{-1} \cos y \, dx - [\sin y \ln(5x+15) - y - 1] \, dy = 0$.

(a) Let $M = (x+3)^{-1} \cos y$ and $N = -[\sin y \ln(5x+15) - y - 1]$. Then

$$\frac{\partial M}{\partial y} = -\frac{\sin y}{x+3} \quad \text{and} \quad \frac{\partial N}{\partial x} = -\sin y \frac{5}{5x+15} = -\sin y \frac{1}{x+3}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all $x > -3$ and y , the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = (x+3)^{-1} \cos y$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (x+3)^{-1} \cos y \, dx = \cos y \int \frac{1}{x+3} \, dx = \ln(x+3) \cos y + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [\ln(x+3) \cos y + B(y)] = -\ln(x+3) \sin y + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ -\ln(x+3) \sin y + \frac{\partial B}{\partial y} &= -[\sin y \ln(5x+15) - y - 1] \\ -\ln(x+3) \sin y + \frac{\partial B}{\partial y} &= -\sin y \ln(5x+15) + y + 1 \\ -\ln(x+3) \sin y + \frac{\partial B}{\partial y} &= -\sin y \ln(5(x+3)) + y + 1 \\ -\ln(x+3) \sin y + \frac{\partial B}{\partial y} &= -\sin y \ln(5) - \sin y \ln(x+3) + y + 1 \\ \frac{\partial B}{\partial y} &= -\sin y \ln(5) + y + 1\end{aligned}$$

Now we integrate $\frac{dB}{dy} = -\sin y \ln(5) + y + 1$ with respect to y .

$$B(y) = \int (-\sin y \ln(5) + y + 1) \, dy = \ln(5) \cos y + \frac{1}{2}y^2 + y + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = \ln(x + 3) \cos y + \ln(5) \cos y + \frac{1}{2}y^2 + y + C$$

The general solution of the differential equation is

$$\ln(x + 3) \cos y + \ln(5) \cos y + \frac{1}{2}y^2 + y + C = 0$$

where C is a constant.

14. Consider the differential equation $p^2 \sec(2\theta) \tan(2\theta) d\theta + p[\sec(2\theta) + 2] dp = 0$.

(a) Let $M = p^2 \sec(2\theta) \tan(2\theta)$ and $N = p[\sec(2\theta) + 2]$. Then

$$\frac{\partial M}{\partial p} = 2p \sec(2\theta) \tan(2\theta) \quad \text{and} \quad \frac{\partial N}{\partial \theta} = 2p \sec(2\theta) \tan(2\theta)$$

Since $\frac{\partial M}{\partial p} = \frac{\partial N}{\partial \theta}$ for all θ and p where defined, the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial \theta} = M = p^2 \sec(2\theta) \tan(2\theta)$ partially with respect to θ (holding p constant). Then

$$f(\theta, p) = \int p^2 \sec(2\theta) \tan(2\theta) d\theta = \frac{1}{2}p^2 \sec(2\theta) + B(p)$$

where the constant of integration B is a function of p alone. Find $\frac{\partial f}{\partial p}$.

$$\frac{\partial f}{\partial p} = \frac{\partial}{\partial p} \left[\frac{1}{2}p^2 \sec(2\theta) + B(p) \right] = p \sec(2\theta) + \frac{\partial B}{\partial p}$$

The function f satisfies $\frac{\partial f}{\partial p} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial p} &= N \\ p \sec(2\theta) + \frac{\partial B}{\partial p} &= p[\sec(2\theta) + 2] \\ \frac{\partial B}{\partial p} &= 2p \end{aligned}$$

Now we integrate $\frac{dB}{dp} = 2p$ with respect to p .

$$B(p) = \int 2p dp = p^2 + C$$

Substituting for $B(p)$ in the function $f(\theta, p)$, we obtain

$$f(\theta, p) = \frac{1}{2}p^2 \sec(2\theta) + p^2 + C$$

The general solution of the differential equation is

$$\frac{1}{2}p^2 \sec(2\theta) + p^2 + C = 0$$

where C is a constant.

15. Consider the differential equation $\cos(x + y^2) dx + 2y \cos(x + y^2) dy = 0$.

(a) Let $M = \cos(x + y^2)$ and $N = 2y \cos(x + y^2)$. Then

$$\frac{\partial M}{\partial y} = -2y \sin(x + y^2) \quad \text{and} \quad \frac{\partial N}{\partial x} = -2y \sin(x + y^2)$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = \cos(x + y^2)$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \cos(x + y^2) dx = \sin(x + y^2) + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [\sin(x + y^2) + B(y)] = 2y \cos(x + y^2) + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 2y \cos(x + y^2) + \frac{\partial B}{\partial y} &= 2y \cos(x + y^2) \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = \sin(x + y^2) + C$$

The general solution of the differential equation is

$$\boxed{\sin(x + y^2) + C = 0}$$

where C is a constant.

16. Consider the differential equation $[\sin(2\theta) - 2p \cos(2\theta)] dp + [2p \cos(2\theta) + 2p^2 \sin(2\theta)] d\theta = 0$.

(a) Let $M = [\sin(2\theta) - 2p \cos(2\theta)]$ and $N = 2p \cos(2\theta) + 2p^2 \sin(2\theta)$. Then

$$\frac{\partial M}{\partial \theta} = 2 \cos(2\theta) + 4p \sin(2\theta) \quad \text{and} \quad \frac{\partial N}{\partial p} = 2 \cos(2\theta) + 4p \sin(2\theta)$$

Since $\frac{\partial M}{\partial \theta} = \frac{\partial N}{\partial p}$ for all p and θ , the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial p} = M = [\sin(2\theta) - 2p \cos(2\theta)]$ partially with respect to p (holding θ constant). Then

$$f(p, \theta) = \int [\sin(2\theta) - 2p \cos(2\theta)] dp = p \sin(2\theta) - p^2 \cos(2\theta) + B(\theta)$$

where the constant of integration B is a function of θ alone. Find $\frac{\partial f}{\partial \theta}$.

$$\frac{\partial f}{\partial \theta} = \frac{\partial}{\partial \theta} [p \sin(2\theta) - p^2 \cos(2\theta) + B(\theta)] = 2p \cos(2\theta) + 2p^2 \sin(2\theta) + \frac{\partial B}{\partial \theta}$$

The function f satisfies $\frac{\partial f}{\partial \theta} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial \theta} &= N \\ 2p \cos(2\theta) + 2p^2 \sin(2\theta) + \frac{\partial B}{\partial \theta} &= 2p \cos(2\theta) + 2p^2 \sin(2\theta) \\ \frac{\partial B}{\partial \theta} &= 0\end{aligned}$$

$B(\theta)$ must equal a constant. Let $B(\theta) = C$ and substitute it in the function $f(p, \theta)$, we obtain

$$f(p, \theta) = p \sin(2\theta) - p^2 \cos(2\theta) + C$$

The general solution of the differential equation is

$$\boxed{p \sin(2\theta) - p^2 \cos(2\theta) + C = 0}$$

where C is a constant.

17. Consider the differential equation $(2ye^{2x} - x^2) dx + e^{2x} dy = 0$.

(a) Let $M = 2ye^{2x} - x^2$ and $N = e^{2x}$. Then

$$\frac{\partial M}{\partial y} = 2e^{2x} \quad \text{and} \quad \frac{\partial N}{\partial x} = 2e^{2x}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = 2ye^{2x} - x^2$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (2ye^{2x} - x^2) dx = ye^{2x} - \frac{1}{3}x^3 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[ye^{2x} - \frac{1}{3}x^3 + B(y) \right] = e^{2x} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ e^{2x} + \frac{\partial B}{\partial y} &= e^{2x} \\ \frac{\partial B}{\partial y} &= 0\end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = ye^{2x} - \frac{1}{3}x^3 + C$$

The general solution of the differential equation is

$$\boxed{ye^{2x} - \frac{1}{3}x^3 + C = 0}$$

where C is a constant.

18. Consider the differential equation $(2xye^{x^2} - 3x^2) dx + e^{x^2} dy = 0$.

(a) Let $M = 2xye^{x^2} - 3x^2$ and $N = e^{x^2}$. Then

$$\frac{\partial M}{\partial y} = 2xe^{x^2} \quad \text{and} \quad \frac{\partial N}{\partial x} = 2xe^{x^2}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = 2xye^{x^2} - 3x^2$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int (2xye^{x^2} - 3x^2) dx = ye^{x^2} - x^3 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [ye^{x^2} - x^3 + B(y)] = e^{x^2} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ e^{x^2} + \frac{\partial B}{\partial y} &= e^{x^2} \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = ye^{x^2} - x^3 + C$$

The general solution of the differential equation is

$$\boxed{ye^{x^2} - x^3 + C = 0}$$

where C is a constant.

19. Consider the differential equation $\left[\frac{1}{x+y} + y^2 \right] dx + \left[\frac{1}{x+y} + 2xy \right] dy = 0$.

(a) Let $M = \frac{1}{x+y} + y^2$ and $N = \frac{1}{x+y} + 2xy$. Then

$$\frac{\partial M}{\partial y} = -\frac{1}{(x+y)^2} + 2y \quad \text{and} \quad \frac{\partial N}{\partial x} = -\frac{1}{(x+y)^2} + 2y$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ when $x+y \neq 0$, the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = \frac{1}{x+y} + y^2$ partially with respect to x (holding y constant).
Then

$$f(x, y) = \int \left[\frac{1}{x+y} + y^2 \right] dx = \ln|x+y| + xy^2 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [\ln |x + y| + xy^2 + B(y)] = \frac{1}{x + y} + 2xy + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ \frac{1}{x + y} + 2xy + \frac{\partial B}{\partial y} &= \frac{1}{x + y} + 2xy \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = \ln |x + y| + xy^2 + C$$

The general solution of the differential equation is

$$\boxed{\ln |x + y| + xy^2 + C = 0}$$

where C is a constant.

20. Consider the differential equation $\frac{y^2 - 2x^2}{xy^2 - x^3} dx + \frac{2y^2 - x^2}{y^3 - x^2y} dy = 0$.

(a) Let $M = \frac{y^2 - 2x^2}{xy^2 - x^3}$ and $N = \frac{2y^2 - x^2}{y^3 - x^2y}$. Then

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y} \left(\frac{y^2 - 2x^2}{xy^2 - x^3} \right) \\ &= \frac{(xy^2 - x^3)(2y) - (y^2 - 2x^2)(2xy)}{(xy^2 - x^3)^2} \\ &= \frac{2x^3y}{(xy^2 - x^3)^2} \\ &= \frac{2x^3y}{x^2(y^2 - x^2)^2} \\ &= \frac{2xy}{(y^2 - x^2)^2} \end{aligned}$$

and

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x} \left(\frac{2y^2 - x^2}{y^3 - x^2y} \right) \\ &= \frac{(y^3 - x^2y)(-2x) - (2y^2 - x^2)(-2xy)}{(y^3 - x^2y)^2} \\ &= \frac{2xy^3}{(y^3 - x^2y)^2} \\ &= \frac{2xy^3}{y^2(y^2 - x^2)^2} \\ &= \frac{2xy}{(y^2 - x^2)^2} \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ when $x \neq 0$, $y \neq 0$, $x \neq y$ and $x \neq -y$, the differential equation is exact.

(b) Find f by integrating $\frac{\partial f}{\partial x} = M = \frac{y^2 - 2x^2}{xy^2 - x^3}$ partially with respect to x (holding y constant). Then

$$\begin{aligned} f(x, y) &= \int \frac{y^2 - 2x^2}{xy^2 - x^3} dx \\ &= \int \left(\frac{1}{x} - \frac{1}{2} \frac{1}{y-x} + \frac{1}{2} \frac{1}{y+x} \right) dx \\ &= \ln|x| + \frac{1}{2} \ln|y-x| + \frac{1}{2} \ln|y+x| + B(y) \end{aligned}$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[\ln|x| + \frac{1}{2} \ln|y-x| + \frac{1}{2} \ln|y+x| + B(y) \right] = \frac{1}{2(y-x)} + \frac{1}{2(y+x)} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ \frac{1}{2(y-x)} + \frac{1}{2(y+x)} + \frac{\partial B}{\partial y} &= \frac{2y^2 - x^2}{y^3 - x^2y} \\ \frac{y}{y^2 - x^2} + \frac{\partial B}{\partial y} &= \frac{2y^2 - x^2}{y^3 - x^2y} \\ \frac{y^2}{y^3 - x^2y} + \frac{\partial B}{\partial y} &= \frac{2y^2 - x^2}{y^3 - x^2y} \\ \frac{y^2}{y^3 - x^2y} + \frac{\partial B}{\partial y} &= \frac{y^2}{y^3 - x^2y} + \frac{y^2 - x^2}{y^3 - x^2y} \\ \frac{y^2}{y^3 - x^2y} + \frac{\partial B}{\partial y} &= \frac{y^2}{y^3 - x^2y} + \frac{y^2 - x^2}{y(y^2 - x^2)} \\ \frac{y^2}{y^3 - x^2y} + \frac{\partial B}{\partial y} &= \frac{y^2}{y^3 - x^2y} + \frac{1}{y} \\ \frac{\partial B}{\partial y} &= \frac{1}{y} \end{aligned}$$

Now we integrate $\frac{dB}{dy} = \frac{1}{y}$ with respect to y .

$$B(y) = \int \frac{1}{y} dy = \ln|y| + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = \ln|x| + \frac{1}{2} \ln|y-x| + \frac{1}{2} \ln|y+x| + \ln|y| + C$$

The general solution of the differential equation is

$$\ln|x| + \frac{1}{2} \ln|y-x| + \frac{1}{2} \ln|y+x| + \ln|y| + C = 0$$

where C is a constant.

21. Consider the differential equation $2y^3 \sin(2x) dx - 3y^2 \cos(2x) dy = 0$.

- (a) Let $M = 2y^3 \sin(2x)$ and $N = -3y^2 \cos(2x)$. Then

$$\frac{\partial M}{\partial y} = 6y^2 \sin(2x) \quad \text{and} \quad \frac{\partial N}{\partial x} = 6y^2 \sin(2x)$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M = 2y^3 \sin(2x)$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int 2y^3 \sin(2x) dx = -y^3 \cos(2x) + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [-y^3 \cos(2x) + B(y)] = -3y^2 \cos(2x) + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ -3y^2 \cos(2x) + \frac{\partial B}{\partial y} &= -3y^2 \cos(2x) \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substitute it in the function $f(x, y)$, we obtain

$$f(x, y) = -y^3 \cos(2x) + C$$

The general solution of the differential equation is

$$\boxed{-y^3 \cos(2x) + C = 0}$$

where C is a constant.

22. Consider the differential equation $\frac{3y^2}{x^2 + 3x} dx + \left(2y \ln \frac{5x}{x+3} + 3 \sin y \right) dy = 0$.

- (a) Let $M = \frac{3y^2}{x^2 + 3x}$ and $N = 2y \ln \frac{5x}{x+3} + 3 \sin y$. Then

$$\frac{\partial M}{\partial y} = \frac{6y}{x^2 + 3x} \quad \text{and} \quad \frac{\partial N}{\partial x} = 2y \frac{1}{\frac{5x}{x+3}} \cdot \frac{(x+3)(5) - 5x}{(x+3)^2} = 2y \frac{x+3}{5x} \cdot \frac{15}{(x+3)^2} = \frac{6y}{x(x+3)}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ on the domain $\{(x, y) | x < -3 \text{ or } x > 0\}$, the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M = \frac{3y^2}{x^2 + 3x}$ partially with respect to x (holding y constant). Then

$$\begin{aligned} f(x, y) &= \int \frac{3y^2}{x^2 + 3x} dx \\ &= y^2 \int \left(\frac{1}{x} - \frac{1}{x+3} \right) dx \\ &= y^2 (\ln |x| - \ln |x+3|) + B(y) \\ &= y^2 \ln \left| \frac{x}{x+3} \right| + B(y) \\ &= y^2 \ln \frac{x}{x+3} + B(y) \end{aligned}$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[y^2 \ln \frac{x}{x+3} + B(y) \right] = 2y \ln \frac{x}{x+3} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 2y \ln \frac{x}{x+3} + \frac{\partial B}{\partial y} &= 2y \ln \frac{5x}{x+3} + 3 \sin y \\ 2y \ln \frac{x}{x+3} + \frac{\partial B}{\partial y} &= 2y \ln \frac{x}{x+3} + 2y \ln(5) + 3 \sin y \\ \frac{\partial B}{\partial y} &= 2y \ln(5) + 3 \sin y \end{aligned}$$

Now we integrate $\frac{dB}{dy} = 2y \ln(5) + 3 \sin y$ with respect to y .

$$B(y) = \int (2y \ln(5) + 3 \sin y) dy = y^2 \ln(5) - 3 \cos y + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$\begin{aligned} f(x, y) &= y^2 \ln \frac{x}{x+3} + y^2 \ln(5) - 3 \cos y + C \\ &= y^2 \left(\ln \frac{x}{x+3} + \ln(5) \right) - 3 \cos y + C \\ &= y^2 \ln \frac{5x}{x+3} - 3 \cos y + C \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y^2 \ln \frac{5x}{x+3} - 3 \cos y + C = 0}$$

where C is a constant.

23. Consider the differential equation $(1 + y^2 + xy^2) dx + (x^2y + y + 2xy) dy = 0$, with $y(1) = 1$. Let $M = 1 + y^2 + xy^2$ and $N = x^2y + y + 2xy$. Find f by integrating $\frac{\partial f}{\partial x} = M = 1 + y^2 + xy^2$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (1 + y^2 + xy^2) dx = x + xy^2 + \frac{1}{2}x^2y^2 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[x + xy^2 + \frac{1}{2}x^2y^2 + B(y) \right] = 2xy + x^2y + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 2xy + x^2y + \frac{\partial B}{\partial y} &= x^2y + y + 2xy \\ \frac{\partial B}{\partial y} &= y \end{aligned}$$

Now we integrate $\frac{dB}{dy} = y$ with respect to y .

$$B(y) = \int y \, dy = \frac{1}{2}y^2 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = x + xy^2 + \frac{1}{2}x^2y^2 + \frac{1}{2}y^2 + C$$

The general solution of the differential equation is $x + xy^2 + \frac{1}{2}x^2y^2 + \frac{1}{2}y^2 + C = 0$, where C is a constant. To find the particular solution, substitute $x = 1$ and $y = 1$ and solve for C .

$$\begin{aligned} x + xy^2 + \frac{1}{2}x^2y^2 + \frac{1}{2}y^2 + C &= 0 \\ 1 + 1 + \frac{1}{2} + \frac{1}{2} + C &= 0 \\ C &= -3 \end{aligned}$$

The particular solution is $\boxed{x + xy^2 + \frac{1}{2}x^2y^2 + \frac{1}{2}y^2 - 3 = 0}$.

24. Consider the differential equation $(3x^2y^{-1} + 2x) \, dx + (y^2 - x^3y^{-2}) \, dy = 0$, with $y(3) = 3$. Let $M = 3x^2y^{-1} + 2x$ and $N = y^2 - x^3y^{-2}$. Find f by integrating $\frac{\partial f}{\partial x} = M = 3x^2y^{-1} + 2x$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (3x^2y^{-1} + 2x) \, dx = x^3y^{-1} + x^2 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [x^3y^{-1} + x^2 + B(y)] = -x^3y^{-2} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ -x^3y^{-2} + \frac{\partial B}{\partial y} &= y^2 - x^3y^{-2} \\ \frac{\partial B}{\partial y} &= y^2 \end{aligned}$$

Now we integrate $\frac{dB}{dy} = y^2$ with respect to y .

$$B(y) = \int y^2 \, dy = \frac{1}{3}y^3 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = x^3y^{-1} + x^2 + \frac{1}{3}y^3 + C$$

The general solution of the differential equation is $x^3y^{-1} + x^2 + \frac{1}{3}y^3 + C = 0$, where C is a constant. To find the particular solution, substitute $x = 3$ and $y = 3$ and solve for C .

$$\begin{aligned}x^3y^{-1} + x^2 + \frac{1}{3}y^3 + C &= 0 \\ \frac{3^3}{3} + 3^2 + \frac{1}{3}3^3 + C &= 0 \\ C &= -27\end{aligned}$$

The particular solution is $\boxed{x^3y^{-1} + x^2 + \frac{1}{3}y^3 - 27 = 0}$.

25. Consider the differential equation $(2xy - \sin x) dx + (x^2 - 2y) dy = 0$, with $y(0) = 1$. Let $M = 2xy - \sin x$ and $N = x^2 - 2y$. Find f by integrating $\frac{\partial f}{\partial x} = M = 2xy - \sin x$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (2xy - \sin x) dx = x^2y + \cos x + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [x^2y + \cos x + B(y)] = x^2 + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ x^2 + \frac{\partial B}{\partial y} &= x^2 - 2y \\ \frac{\partial B}{\partial y} &= -2y\end{aligned}$$

Now we integrate $\frac{dB}{dy} = -2y$ with respect to y .

$$B(y) = - \int 2y dy = -y^2 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = x^2y + \cos x - y^2 + C$$

The general solution of the differential equation is $x^2y + \cos x - y^2 + C = 0$, where C is a constant. To find the particular solution, substitute $x = 0$ and $y = 1$ and solve for C .

$$\begin{aligned}x^2y + \cos x - y^2 + C &= 0 \\ 0 + \cos 0 - 1 + C &= 0 \\ C &= 0\end{aligned}$$

The particular solution is $\boxed{x^2y + \cos x - y^2 = 0}$.

26. Consider the differential equation $y[y + \sin x] dx - \left[\cos x - 2xy + \frac{1}{1+y^2} \right] dy = 0$, with $y(0) = 1$. Let $M = y[y + \sin x]$ and $N = 2xy - \cos x - \frac{1}{1+y^2}$. Find f by integrating $\frac{\partial f}{\partial x} = M = y[y + \sin x]$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int y[y + \sin x] dx = \int [y^2 + y \sin x] dx = xy^2 - y \cos x + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [xy^2 - y \cos x + B(y)] = 2xy - \cos x + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 2xy - \cos x + \frac{\partial B}{\partial y} &= 2xy - \cos x - \frac{1}{1+y^2} \\ \frac{\partial B}{\partial y} &= -\frac{1}{1+y^2} \end{aligned}$$

Now we integrate $\frac{dB}{dy} = -\frac{1}{1+y^2}$ with respect to y .

$$B(y) = -\int \frac{1}{1+y^2} dy = -\tan^{-1} y + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = xy^2 - y \cos x - \tan^{-1} y + C$$

The general solution of the differential equation is $xy^2 - y \cos x - \tan^{-1} y + C = 0$, where C is a constant. To find the particular solution, substitute $x = 0$ and $y = 1$ and solve for C .

$$\begin{aligned} xy^2 - y \cos x - \tan^{-1} y + C &= 0 \\ 0 - \cos 0 - \tan^{-1}(1) + C &= 0 \\ C &= 1 + \frac{\pi}{4} \end{aligned}$$

The particular solution is $\boxed{xy^2 - y \cos x - \tan^{-1} y + 1 + \frac{\pi}{4} = 0}$.

Applications and Extensions

27. Suppose the equation $M(x, y) dx + N(x, y) dy = 0$ has the property that

$$g(y) = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{M}$$

is a function of y only. Let $u(y) = e^{\int g(y) dy}$ so that

$$\begin{aligned} \frac{du}{dy} &= \frac{d}{dy} \left[e^{\int g(y) dy} \right] \\ &= e^{\int g(y) dy} \frac{d}{dy} \left[\int g(y) dy \right] \\ &= e^{\int g(y) dy} g(y) \\ &= u(y)g(y) \end{aligned}$$

To show that $u(y)[M(x, y) dx + N(x, y) dy] = 0$ is exact, let $M_1(x, y) = u(y)M(x, y)$ and $N_1(x, y) = u(y)N(x, y)$ so that

$$u(y)[M(x, y) dx + N(x, y) dy] = M_1(x, y) dx + N_1(x, y) dy = 0$$

Then

$$\begin{aligned}
 \frac{\partial M_1}{\partial y} &= \frac{\partial}{\partial y} [u(y)M(x, y)] \\
 &= \frac{\partial u}{\partial y} M(x, y) + u(y) \frac{\partial M}{\partial y} \\
 &= \frac{du}{dy} M(x, y) + u(y) \frac{\partial M}{\partial y} \\
 &= u(y)g(y)M(x, y) + u(y) \frac{\partial M}{\partial y} \\
 &= u(y) \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{M} M(x, y) + u(y) \frac{\partial M}{\partial y} \\
 &= u(y) \frac{\partial N}{\partial x} - u(y) \frac{\partial M}{\partial y} + u(y) \frac{\partial M}{\partial y} \\
 &= u(y) \frac{\partial N}{\partial x}
 \end{aligned}$$

and, because $u(y)$ is a function of y only,

$$\frac{\partial N_1}{\partial x} = \frac{\partial}{\partial x} [u(y)N(x, y)] = u(y) \frac{\partial N}{\partial x}$$

Since $\frac{\partial M_1}{\partial y} = \frac{\partial N_1}{\partial x}$ for all x and y , the differential equation $u(y)[M(x, y) dx + N(x, y) dy] = 0$ is exact.

28. Suppose the equation $M(x, y) dx + N(x, y) dy = 0$ has the property that

$$g(x) = \frac{\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}}{N}$$

is a function of x only. Let $u(x) = e^{\int g(x) dx}$ so that

$$\begin{aligned}
 \frac{du}{dx} &= \frac{d}{dx} \left[e^{\int g(x) dx} \right] \\
 &= e^{\int g(x) dx} \frac{d}{dx} \left[\int g(x) dx \right] \\
 &= e^{\int g(x) dx} g(x) \\
 &= u(x)g(x)
 \end{aligned}$$

To show that $u(x)[M(x, y) dx + N(x, y) dy] = 0$ is exact, let $M_1(x, y) = u(x)M(x, y)$ and $N_1(x, y) = u(x)N(x, y)$ so that

$$u(x)[M(x, y) dx + N(x, y) dy] = M_1(x, y) dx + N_1(x, y) dy = 0$$

Then because $u(x)$ is a function of x only,

$$\frac{\partial M_1}{\partial y} = \frac{\partial}{\partial y} [u(x)M(x, y)] = u(x) \frac{\partial M}{\partial y}$$

and

$$\begin{aligned}
 \frac{\partial N_1}{\partial x} &= \frac{\partial}{\partial x} [u(x)N(x, y)] \\
 &= \frac{\partial u}{\partial x} N(x, y) + u(x) \frac{\partial N}{\partial x} \\
 &= \frac{du}{dx} N(x, y) + u(x) \frac{\partial N}{\partial x} \\
 &= u(x)g(x)N(x, y) + u(x) \frac{\partial N}{\partial x} \\
 &= u(x) \frac{\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}}{N} N(x, y) + u(x) \frac{\partial N}{\partial x} \\
 &= u(x) \frac{\partial M}{\partial y} - u(x) \frac{\partial N}{\partial x} + u(x) \frac{\partial N}{\partial x} \\
 &= u(x) \frac{\partial M}{\partial y}
 \end{aligned}$$

Since $\frac{\partial M_1}{\partial y} = \frac{\partial N_1}{\partial x}$ for all x and y , the differential equation $u(x)[M(x, y) dx + N(x, y) dy] = 0$ is exact.

29. Consider the differential equation $(4x^2 + y^2 + 1) dx + (x^2 - 2xy) dy = 0$.

(a) Let $M = 4x^2 + y^2 + 1$ and $N = x^2 - 2xy$. Since $\frac{\partial M}{\partial y} = 2y$ and $\frac{\partial N}{\partial x} = 2x - 2y$,

$$\frac{\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}}{N} = \frac{4y - 2x}{x^2 - 2xy} = \frac{2(2y - x)}{x(x - 2y)} = -\frac{2}{x}$$

Let

$$u(x) = e^{\left[-\int \frac{2}{x} dx\right]} = e^{-2 \ln(x)} = e^{\ln(x^{-2})} = x^{-2} = \frac{1}{x^2}$$

Then the equation

$$\left(4 + \frac{y^2}{x^2} + \frac{1}{x^2}\right) dx + \left(1 - \frac{2y}{x}\right) dy = 0$$

is exact.

(b) Let $M_1 = 4 + \frac{y^2}{x^2} + \frac{1}{x^2}$ and $N_1 = \frac{x - 2y}{x}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \left(4 + \frac{y^2}{x^2} + \frac{1}{x^2}\right) dx = 4x - \frac{y^2}{x} - \frac{1}{x} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[4x - \frac{y^2}{x} - \frac{1}{x} + B(y)\right] = -\frac{2y}{x} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned}
 \frac{\partial f}{\partial y} &= N_1 \\
 -\frac{2y}{x} + \frac{\partial B}{\partial y} &= \frac{x - 2y}{x} \\
 -\frac{2y}{x} + \frac{\partial B}{\partial y} &= 1 - \frac{2y}{x} \\
 \frac{\partial B}{\partial y} &= 1
 \end{aligned}$$

Now we integrate $\frac{dB}{dy} = 1$ with respect to y .

$$B(y) = \int 1 \, dy = y + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = 4x - \frac{y^2}{x} - \frac{1}{x} + y + C$$

The general solution of the differential equation is

$$\boxed{4x - \frac{y^2}{x} - \frac{1}{x} + y + C = 0}$$

where C is a constant.

- (c) Differentiate $4x - \frac{y^2}{x} - \frac{1}{x} + y + C = 0$ with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} \frac{d}{dx} \left(4x - \frac{y^2}{x} - \frac{1}{x} + y + C \right) &= 0 \\ 4 - \frac{(x)(2yy') - y^2}{x^2} + \frac{1}{x^2} + y' &= 0 \\ 4x^2 - 2xyy' + y^2 + 1 + y' &= 0 \\ 4x^2 + y^2 + 1 + (1 - 2xy)y' &= 0 \\ 4x^2 + y^2 + 1 + (1 - 2xy)\frac{dy}{dx} &= 0 \end{aligned}$$

The equivalent differential form is

$$(4x^2 + y^2 + 1) \, dx + (x^2 - 2xy) \, dy = 0$$

so $4x - \frac{y^2}{x} - \frac{1}{x} + y + C = 0$ is a solution this differential equation as well.

30. Consider the differential equation $4x^2y \, dx + (x^3 + y) \, dy = 0$.

- (a) Let $M = 4x^2y$ and $N = x^3 + y$. Since $\frac{\partial M}{\partial y} = 4x^2$ and $\frac{\partial N}{\partial x} = 3x^2$,

$$\frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{M} = \frac{-x^2}{4x^2y} = -\frac{1}{4y}$$

Let

$$u(y) = e^{\left[-\int \frac{1}{4y} \, dy\right]} = e^{-\frac{1}{4} \ln(y)} = e^{\ln(y^{-1/4})} = y^{-1/4}$$

Then the equation

$$\boxed{4x^2y^{3/4} \, dx + (x^3y^{-1/4} + y^{3/4}) \, dy = 0}$$

is exact.

- (b) Let $M_1 = 4x^2y^{3/4}$ and $N_1 = x^3y^{-1/4} + y^{3/4}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1 = 4x^2y^{3/4}$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int 4x^2y^{3/4} \, dx = \frac{4}{3}x^3y^{3/4} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[\frac{4}{3}x^3y^{3/4} + B(y) \right] = x^3y^{-1/4} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N_1 \\ x^3y^{-1/4} + \frac{\partial B}{\partial y} &= x^3y^{-1/4} + y^{3/4} \\ \frac{\partial B}{\partial y} &= y^{3/4} \end{aligned}$$

Now we integrate $\frac{dB}{dy} = y^{3/4}$ with respect to y .

$$B(y) = \int y^{3/4} dy = \frac{4}{7}y^{7/4} + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = \frac{4}{3}x^3y^{3/4} + \frac{4}{7}y^{7/4} + C$$

The general solution of the differential equation is

$$\boxed{\frac{4}{3}x^3y^{3/4} + \frac{4}{7}y^{7/4} + C = 0}$$

where C is a constant.

(c) Differentiate $\frac{4}{3}x^3y^{3/4} + \frac{4}{7}y^{7/4} + C = 0$ with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} \frac{d}{dx} \left(\frac{4}{3}x^3y^{3/4} + \frac{4}{7}y^{7/4} + C \right) &= 0 \\ 4x^2y^{3/4} + x^3y^{-1/4}\frac{dy}{dx} + y^{3/4}\frac{dy}{dx} &= 0 \\ 4x^2y + x^3\frac{dy}{dx} + y\frac{dy}{dx} &= 0 \quad (\text{multiply by } y^{1/4}) \\ 4x^2y + (x^3 + y)\frac{dy}{dx} &= 0 \end{aligned}$$

The equivalent differential form is

$$4x^2y dx + (x^3 + y) dy = 0$$

so $\frac{4}{3}x^3y^{3/4} + \frac{4}{7}y^{7/4} + C = 0$ is a solution this differential equation as well.

31. Consider the differential equation $y dx + (x^2y - x) dy = 0$.

(a) Let $M = y$ and $N = x^2y - x$. Since $\frac{\partial M}{\partial y} = 1$ and $\frac{\partial N}{\partial x} = 2xy - 1$,

$$\frac{\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}}{N} = \frac{2 - 2xy}{x^2y - x} = \frac{2(1 - xy)}{x(xy - 1)} = -\frac{2}{x}$$

Let

$$u(x) = e^{\left[-\int \frac{2}{x} dx\right]} = e^{-2 \ln(x)} = e^{\ln(x^{-2})} = x^{-2} = \frac{1}{x^2}$$

Then the equation

$$\boxed{\frac{y}{x^2} dx + \left(y - \frac{1}{x}\right) dy = 0}$$

is exact.

- (b) Let $M_1 = \frac{y}{x^2}$ and $N_1 = y - \frac{1}{x}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \frac{y}{x^2} dx = -\frac{y}{x} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[-\frac{y}{x} + B(y)\right] = -\frac{1}{x} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N_1 \\ -\frac{1}{x} + \frac{\partial B}{\partial y} &= y - \frac{1}{x} \\ \frac{\partial B}{\partial y} &= y \end{aligned}$$

Now we integrate $\frac{dB}{dy} = y$ with respect to y .

$$B(y) = \int y dy = \frac{1}{2}y^2 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = -\frac{y}{x} + \frac{1}{2}y^2 + C$$

The general solution of the differential equation is

$$\boxed{-\frac{y}{x} + \frac{1}{2}y^2 + C = 0}$$

where C is a constant.

- (c) Differentiate $-\frac{y}{x} + \frac{1}{2}y^2 + C = 0$ with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} \frac{d}{dx} \left(-\frac{y}{x} + \frac{1}{2}y^2 + C \right) &= 0 \\ -\frac{xy' - y}{x^2} + yy' &= 0 \\ -xy' + y + x^2yy' &= 0 \\ y + (x^2y - x)y' &= 0 \\ y + (x^2y - x)\frac{dy}{dx} &= 0 \end{aligned}$$

The equivalent differential form is

$$y \, dx + (x^2 y - x) \, dy = 0$$

so $-\frac{y}{x} + \frac{1}{2}y^2 + C = 0$ is a solution this differential equation as well.

32. Consider the differential equation $(\cos y + x) \, dx + x \sin y \, dy = 0$.

(a) Let $M = \cos y + x$ and $N = x \sin y$. Since $\frac{\partial M}{\partial y} = -\sin y$ and $\frac{\partial N}{\partial x} = \sin y$,

$$\frac{\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}}{N} = \frac{-2 \sin y}{x \sin y} = -\frac{2}{x}$$

Let

$$u(x) = e^{\left[-\int \frac{2}{x} \, dx\right]} = e^{-2 \ln(x)} = e^{\ln(x^{-2})} = x^{-2} = \frac{1}{x^2}$$

Then the equation

$$\left(\frac{\cos y}{x^2} + \frac{1}{x} \right) dx + \frac{\sin y}{x} dy = 0$$

is exact.

(b) Let $M_1 = \frac{\cos y}{x^2} + \frac{1}{x}$ and $N_1 = \frac{\sin y}{x}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1 = \frac{\cos y}{x^2} + \frac{1}{x}$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \left(\frac{\cos y}{x^2} + \frac{1}{x} \right) dx = -\frac{\cos y}{x} + \ln |x| + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[-\frac{\cos y}{x} + \ln |x| + B(y) \right] = \frac{\sin y}{x} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N_1 \\ \frac{\sin y}{x} + \frac{\partial B}{\partial y} &= \frac{\sin y}{x} \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substituting it in the function $f(x, y)$, we obtain

$$f(x, y) = -\frac{\cos y}{x} + \ln |x| + C$$

The general solution of the differential equation is

$$-\frac{\cos y}{x} + \ln |x| + C = 0$$

where C is a constant.

- (c) Differentiate $-\frac{\cos y}{x} + \ln|x| + C = 0$ with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned}\frac{d}{dx} \left(-\frac{\cos y}{x} + \ln|x| + C \right) &= 0 \\ -\frac{x(-\sin y)y' - \cos y}{x^2} + \frac{1}{x} &= 0 \\ x \sin y y' + \cos y + x &= 0 \\ \cos y + x + x \sin y \frac{dy}{dx} &= 0\end{aligned}$$

The equivalent differential form is

$$(\cos y + x) dx + x \sin y dy = 0$$

so $-\frac{\cos y}{x} + \ln|x| + C = 0$ is a solution this differential equation as well.

33. Consider the differential equation $(x^2 - x \sin y) dx + x^2 \cos y dy = 0$.

- (a) Let $M = x^2 - x \sin y$ and $N = x^2 \cos y$. Since $\frac{\partial M}{\partial y} = -x \cos y$ and $\frac{\partial N}{\partial x} = 2x \cos y$,

$$\frac{\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}}{N} = \frac{-3x \cos y}{x^2 \cos y} = -\frac{3}{x}$$

Let

$$u(x) = e^{\left[-\int \frac{3}{x} dx\right]} = e^{-3 \ln(x)} = e^{\ln(x^{-3})} = x^{-3} = \frac{1}{x^3}$$

Then the equation

$$\left(\left(\frac{1}{x} - \frac{\sin y}{x^2} \right) dx + \frac{\cos y}{x} dy \right) = 0$$

is exact.

- (b) Let $M_1 = \frac{1}{x} - \frac{\sin y}{x^2}$ and $N_1 = \frac{\cos y}{x}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1 = \frac{1}{x} - \frac{\sin y}{x^2}$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \left(\frac{1}{x} - \frac{\sin y}{x^2} \right) dx = \ln|x| + \frac{\sin y}{x} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[\ln|x| + \frac{\sin y}{x} + B(y) \right] = \frac{\cos y}{x} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N_1 \\ \frac{\cos y}{x} + \frac{\partial B}{\partial y} &= \frac{\cos y}{x} \\ \frac{\partial B}{\partial y} &= 0\end{aligned}$$

$B(y)$ must equal a constant. Let $B(y) = C$ and substituting it in the function $f(x, y)$, we obtain

$$f(x, y) = \ln|x| + \frac{\sin y}{x} + C$$

The general solution of the differential equation is

$$\ln |x| + \frac{\sin y}{x} + C = 0$$

where C is a constant.

- (c) Differentiate $\ln |x| + \frac{\sin y}{x} + C = 0$ with respect to x to find $\frac{dy}{dx}$.

$$\begin{aligned} \frac{d}{dx} \left(\ln |x| + \frac{\sin y}{x} + C \right) &= 0 \\ \frac{1}{x} + \frac{x \cos y y' - \sin y}{x^2} &= 0 \\ x^2 + x^2 \cos y y' - x \sin y &= 0 \quad (\text{multiplied by } x^3) \\ x^2 - x \sin y + x^2 \cos y \frac{dy}{dx} &= 0 \end{aligned}$$

The equivalent differential form is

$$(x^2 - x \sin y) dx + x^2 \cos y dy = 0$$

so $\ln |x| + \frac{\sin y}{x} + C = 0$ is a solution this differential equation as well.

Challenge Problem

34. Consider the differential equation

$$\frac{2 \frac{\beta-y}{100} - 2 \cos \frac{\beta-y}{100}}{2 \frac{\alpha-x}{100} + 4 \cos \frac{\alpha-x}{100}} \frac{dy}{dx} = 1$$

- (a) The equation is separable, so rewrite and integrate.

$$\begin{aligned} \frac{2 \frac{\beta-y}{100} - 2 \cos \frac{\beta-y}{100}}{2 \frac{\alpha-x}{100} + 4 \cos \frac{\alpha-x}{100}} \frac{dy}{dx} &= 1 \\ 2 \frac{\beta-y}{100} - 2 \cos \frac{\beta-y}{100} dy &= 2 \frac{\alpha-x}{100} + 4 \cos \frac{\alpha-x}{100} dx \\ \int \left(2 \frac{\beta-y}{100} - 2 \cos \frac{\beta-y}{100} \right) dy &= \int \left(2 \frac{\alpha-x}{100} + 4 \cos \frac{\alpha-x}{100} \right) dx \\ \frac{\beta y}{50} - \frac{y^2}{100} + 200 \sin \frac{\beta-y}{100} &= \frac{\alpha x}{50} - \frac{x^2}{100} - 400 \sin \frac{\alpha-x}{100} + C \end{aligned}$$

The general solution is

$$\frac{\beta y}{50} - \frac{y^2}{100} + 200 \sin \frac{\beta-y}{100} = \frac{\alpha x}{50} - \frac{x^2}{100} - 400 \sin \frac{\alpha-x}{100} + C$$

where C is a constant.

- (b) Express the general solution as

$$\frac{\beta y}{50} - \frac{y^2}{100} + 200 \sin \frac{\beta-y}{100} - \frac{\alpha x}{50} + \frac{x^2}{100} + 400 \sin \frac{\alpha-x}{100} - C = 0$$

Let $f(x, y)$ equal the expression on the left-hand side of the equation, so that

$$f(x, y) = \frac{\beta y}{50} - \frac{y^2}{100} + 200 \sin \frac{\beta-y}{100} - \frac{\alpha x}{50} + \frac{x^2}{100} + 400 \sin \frac{\alpha-x}{100} - C$$

Given $\alpha = 93.43$ and $\beta = 59.12$, the function becomes

$$f(x, y) = \frac{59.12y}{50} - \frac{y^2}{100} + 200 \sin \frac{59.12 - y}{100} - \frac{93.43x}{50} + \frac{x^2}{100} + 400 \sin \frac{93.43 - x}{100} - C$$

Use the initial condition $f(0, 0) = 1247.2$ to find C .

$$f(0, 0) = 1247.2 = 200 \sin(0.5912) + 400 \sin(0.9343) - C$$

Solve for C , $C = 200 \sin(0.5912) + 400 \sin(0.9343) - 1247.2 \approx -814.055$ and

$$f(x, y) = \frac{59.12y}{50} - \frac{y^2}{100} + 200 \sin \frac{59.12 - y}{100} - \frac{93.43x}{50} + \frac{x^2}{100} + 400 \sin \frac{93.43 - x}{100} + 814.055$$

To find the oil concentration at point B , evaluate

$$f(162.14, 250.64) \approx 0.152$$

The oil concentration at point B is 0.152 pounds per million gallons.

16.4 First-Order Linear Differential Equations: Bernoulli Differential Equations

Concepts and Vocabulary

1. True. First-order linear differential equations have the form $\frac{dy}{dx} + P(x)y = Q(x)$, where the functions P and Q are continuous on their domains.
2. True. The first-order linear equation $\frac{dy}{dx} + P(x)y = 0$ is separable, since its differential form is $\frac{1}{y} dy + P(x) dx = 0$.
3. False. Multiplying the first-order linear differential equation $\frac{dy}{dx} + P(x)y = Q(x)$, where $Q(x) \neq 0$, by the integrating factor $e^{\int P(x) dx}$ results in a separable differential equation.
4. False. To solve a Bernoulli equation, $\frac{dy}{dx} + P(x)y = Q(x)y^n$, $n \neq 0$, $n \neq 1$, the first step is to multiply by y^{-n} .

Skill Building

5. The differential equation $\frac{dy}{dx} + 2xy = 0$ is separable. Separate the variables and integrate.

$$\begin{aligned} \frac{1}{y} dy + 2x dx &= 0 \\ \ln |y| + x^2 &= C_1 \\ \ln |y| &= -x^2 + C_1 \\ |y| &= e^{(-x^2 + C_1)} \\ |y| &= e^{-x^2} e^{C_1} \\ y &= \pm e^{-x^2} e^{C_1} \end{aligned}$$

Since C_1 is a constant, we may write $C = \pm e^{C_1}$ where $C \neq 0$ is a constant. The solution is now $y = Ce^{-x^2}$, where $C \neq 0$ is a constant.

Notice that the function $y = 0$ also satisfies the differential equation $\frac{dy}{dx} + 2xy = 0$, so it too is a solution. This particular solution matches the general solution above when $C = 0$. So the general solution is $\boxed{y = Ce^{-x^2}}$, where C is any constant.

6. The differential equation $\frac{dy}{dx} + \frac{1}{x}y = 0$ is separable. Separate the variables and integrate.

$$\begin{aligned}\frac{1}{y} dy + \frac{1}{x} dx &= 0 \\ \ln|y| + \ln|x| &= C_1 \\ \ln|xy| &= C_1 \\ |xy| &= e^{C_1} \\ xy &= \pm e^{C_1} \\ y &= \pm \frac{e^{C_1}}{x}\end{aligned}$$

Since C_1 is a constant, we may write $C = \pm e^{C_1}$ where $C \neq 0$ is a constant. The general solution is $\boxed{y = \frac{C}{x}}$, where $C \neq 0$ is a constant.

7. The differential equation $\frac{dy}{dx} + \frac{1}{x}y = 3x$ is first-order linear. Let $P(x) = \frac{1}{x}$. The integrating factor is

$$\begin{aligned}e^{\int P(x) dx} &= e^{\int x^{-1} dx} \\ &= e^{\ln x} \\ &= x\end{aligned}$$

Now multiply the differential equation by x and obtain

$$x \frac{dy}{dx} + y = 3x^2$$

The left side of the above equation is the derivative of xy , so we can write

$$\frac{d}{dx}(xy) = 3x^2$$

Integrate the equation above.

$$\begin{aligned}xy &= \int 3x^2 dx \\ &= x^3 + C\end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = x^2 + \frac{C}{x}}$$

where C is a constant.

8. The differential equation $\frac{dr}{d\theta} + \frac{4r}{\theta} = \theta$ is first-order linear. Let $P(\theta) = \frac{4}{\theta}$. The integrating factor is

$$\begin{aligned}e^{\int P(\theta) d\theta} &= e^{\int 4\theta^{-1} d\theta} \\ &= e^{4 \ln \theta} \\ &= e^{\ln \theta^4} \\ &= \theta^4\end{aligned}$$

Now multiply the differential equation by θ^4 and obtain

$$\theta^4 \frac{dr}{d\theta} + 4\theta^3 r = \theta^5$$

The left side of the above equation is the derivative of $\theta^4 r$, so we can write

$$\frac{d}{d\theta} (\theta^4 r) = \theta^5$$

Integrate the equation above.

$$\begin{aligned} \theta^4 r &= \int \theta^5 d\theta \\ &= \frac{1}{6} \theta^6 + C \end{aligned}$$

Solve for r . The general solution of the differential equation is

$$r = \frac{1}{6} \theta^2 + \frac{C}{\theta^4}$$

where C is a constant.

9. The differential equation $\frac{dy}{dx} + \frac{y}{x} = x^2$ is first-order linear. Let $P(x) = \frac{1}{x}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int x^{-1} dx} \\ &= e^{\ln x} \\ &= x \end{aligned}$$

Now multiply the differential equation by x and obtain

$$x \frac{dy}{dx} + y = x^3$$

The left side of the above equation is the derivative of xy , so we can write

$$\frac{d}{dx} (xy) = x^3$$

Integrate the equation above.

$$\begin{aligned} xy &= \int x^3 dx \\ &= \frac{1}{4} x^4 + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{1}{4} x^3 + \frac{C}{x}$$

where C is a constant.

10. The differential equation $\frac{dy}{dx} - \frac{2y}{x+1} = 3(x+1)^2$ is first-order linear. Let $P(x) = -\frac{2}{x+1}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= \exp \left[\int -\frac{2}{x+1} dx \right] \\ &= \exp [-2 \ln(x+1)] \\ &= \exp [\ln ((x+1)^{-2})] \\ &= (x+1)^{-2} \end{aligned}$$

Now multiply the differential equation by $(x+1)^{-2}$ and obtain

$$(x+1)^{-2} \frac{dy}{dx} - 2(x+1)^{-1}y = 3$$

The left side of the above equation is the derivative of $(x+1)^{-2}y$, so we can write

$$\frac{d}{dx} ((x+1)^{-2}y) = 3$$

Integrate the equation above.

$$\begin{aligned} (x+1)^{-2}y &= \int 3 dx \\ &= 3x + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = (x+1)^2(3x+C)}$$

where C is a constant.

11. The differential equation $\frac{dy}{dx} - 2y = e^{-x}$ is first-order linear. Let $P(x) = -2$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{-\int 2 dx} \\ &= e^{-2x} \end{aligned}$$

Now multiply the differential equation by e^{-2x} and obtain

$$e^{-2x} \frac{dy}{dx} - 2e^{-2x}y = e^{-3x}$$

The left side of the above equation is the derivative of $e^{-2x}y$, so we can write

$$\frac{d}{dx} (e^{-2x}y) = e^{-3x}$$

Integrate the equation above.

$$\begin{aligned} e^{-2x}y &= \int e^{-3x} dx \\ &= -\frac{1}{3}e^{-3x} + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = -\frac{1}{3}e^{-x} + Ce^{2x}}$$

where C is a constant.

12. The differential equation $\frac{dy}{dx} - \frac{y}{x} = x^{3/2}$ is first-order linear. Let $P(x) = -\frac{1}{x}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int -x^{-1} dx} \\ &= e^{-\ln x} \\ &= e^{\ln(x^{-1})} \\ &= x^{-1} \end{aligned}$$

Now multiply the differential equation by x^{-1} and obtain

$$x^{-1} \frac{dy}{dx} - x^{-2} y = x^{1/2}$$

The left side of the above equation is the derivative of $x^{-1}y$, so we can write

$$\frac{d}{dx} (x^{-1}y) = x^{1/2}$$

Integrate the equation above.

$$\begin{aligned} x^{-1}y &= \int x^{1/2} dx \\ &= \frac{2}{3}x^{3/2} + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{2}{3}x^{5/2} + Cx$$

where C is a constant.

13. The differential equation $\frac{dy}{dx} + \frac{2y}{x} = x^2 + 1$ is first-order linear. Let $P(x) = \frac{2}{x}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int 2x^{-1} dx} \\ &= e^{2 \ln x} \\ &= e^{\ln x^2} \\ &= x^2 \end{aligned}$$

Now multiply the differential equation by x^2 and obtain

$$x^2 \frac{dy}{dx} + 2xy = x^4 + x^2$$

The left side of the above equation is the derivative of x^2y , so we can write

$$\frac{d}{dx} (x^2y) = x^4 + x^2$$

Integrate the equation above.

$$\begin{aligned} x^2y &= \int (x^4 + x^2) dx \\ &= \frac{1}{5}x^5 + \frac{1}{3}x^3 + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{1}{5}x^3 + \frac{1}{3}x + \frac{C}{x^2}$$

where C is a constant.

14. The differential equation $\frac{dy}{dx} + 2xy = 2x$ is first-order linear. Let $P(x) = 2x$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int 2x dx} \\ &= e^{x^2} \end{aligned}$$

Now multiply the differential equation by e^{x^2} and obtain

$$e^{x^2} \frac{dy}{dx} + 2xe^{x^2}y = 2xe^{x^2}$$

The left side of the above equation is the derivative of $e^{x^2}y$, so we can write

$$\frac{d}{dx} \left(e^{x^2}y \right) = 2xe^{x^2}$$

Integrate the equation above.

$$\begin{aligned} e^{x^2}y &= \int 2xe^{x^2} dx \quad \text{Let } u = x^2. \\ &= e^{x^2} + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = 1 + Ce^{-x^2}}$$

where C is a constant.

15. The differential equation $\frac{dy}{dx} + e^xy = e^x$ is first-order linear. Let $P(x) = e^x$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int e^x dx} \\ &= e^{e^x} \end{aligned}$$

Now multiply the differential equation by e^{e^x} and obtain

$$e^{e^x} \frac{dy}{dx} + e^xe^{e^x}y = e^xe^{e^x}$$

The left side of the above equation is the derivative of $e^{e^x}y$, so we can write

$$\frac{d}{dx} \left(e^{e^x}y \right) = e^xe^{e^x}$$

Integrate the equation above.

$$\begin{aligned} e^{e^x}y &= \int e^xe^{e^x} dx \quad \text{Let } u = e^x. \\ &= e^{e^x} + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = 1 + Ce^{-e^x}}$$

where C is a constant.

16. The differential equation $\frac{dy}{dx} + e^{-x}y = e^{-x}$ is first-order linear. Let $P(x) = e^{-x}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int e^{-x} dx} \\ &= e^{-e^{-x}} \end{aligned}$$

Now multiply the differential equation by $e^{-e^{-x}}$ and obtain

$$e^{-e^{-x}} \frac{dy}{dx} + e^{-x}e^{-e^{-x}}y = e^{-x}e^{-e^{-x}}$$

The left side of the above equation is the derivative of $e^{-e^{-x}}y$, so we can write

$$\frac{d}{dx} \left(e^{-e^{-x}} y \right) = e^{-x} e^{-e^{-x}}$$

Integrate the equation above.

$$\begin{aligned} e^{-e^{-x}} y &= \int e^{-x} e^{-e^{-x}} dx && \text{Let } u = -e^{-x}. \\ &= e^{-e^{-x}} + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = 1 + C e^{e^{-x}}}$$

where C is a constant.

17. The differential equation $\frac{dy}{dx} + y \tan x = \cos x$ is first-order linear. Let $P(x) = \tan x$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int \tan x dx} \\ &= e^{\ln(\sec x)} \\ &= \sec x \end{aligned}$$

Now multiply the differential equation by $\sec x$ and obtain

$$\sec x \frac{dy}{dx} + y \sec x \tan x = \cos x \sec x = 1$$

The left side of the above equation is the derivative of $y \sec x$, so we can write

$$\frac{d}{dx} (y \sec x) = 1$$

Integrate the equation above.

$$\begin{aligned} y \sec x &= \int dx \\ &= x + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = x \cos x + C \cos x}$$

where C is a constant.

18. The differential equation $\frac{dy}{dx} - y \csc x = \sin 2x$ is first-order linear. Let $P(x) = -\csc x$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{-\int \csc x dx} \\ &= e^{\ln(\csc x + \cot x)} \\ &= \csc x + \cot x \end{aligned}$$

(Note: There are several forms for the integral $\int \csc x dx$. It can be shown that $\ln |\csc x - \cot x| = -\ln |\csc x + \cot x|$. The form chosen makes the cancelation easiest.) Now multiply the differential

equation by $\csc x + \cot x$ and obtain

$$\begin{aligned}
 (\csc x + \cot x) \frac{dy}{dx} - y(\csc^2 x + \csc x \cot x) &= \sin 2x(\csc x + \cot x) \\
 &= 2 \sin x \cos x \left(\frac{1}{\sin x} + \frac{\cos x}{\sin x} \right) \\
 &= 2 \cos x + 2 \cos^2 x \\
 &= 2 \cos x + 1 + \cos 2x
 \end{aligned}$$

The left side of the above equation is the derivative of $(\csc x + \cot x)y$, so we can write

$$\frac{d}{dx} ((\csc x + \cot x)y) = 2 \cos x + 1 + \cos 2x$$

Integrate the equation above.

$$\begin{aligned}
 (\csc x + \cot x)y &= \int (2 \cos x + 1 + \cos 2x) dx \\
 &= 2 \sin x + x + \frac{1}{2} \sin 2x + C \\
 &= 2 \sin x + x + \sin x \cos x + C
 \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{2 \sin x + x + \sin x \cos x + C}{\csc x + \cot x}$$

where C is a constant.

19. The differential equation $\frac{dy}{dx} + y \cot x = \csc^2 x$ is first-order linear. Let $P(x) = \cot x$. The integrating factor is

$$\begin{aligned}
 e^{\int P(x) dx} &= e^{\int \cot x dx} \\
 &= e^{\ln(\sin x)} \\
 &= \sin x
 \end{aligned}$$

Now multiply the differential equation by $\sin x$ and obtain

$$\sin x \frac{dy}{dx} + y \cos x = \csc x$$

The left side of the above equation is the derivative of $y \sin x$, so we can write

$$\frac{d}{dx} (y \sin x) = \csc x$$

Integrate the equation above.

$$\begin{aligned}
 y \sin x &= \int \csc x dx \\
 &= \ln |\csc x - \cot x| + C
 \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{\ln |\csc x - \cot x| + C}{\sin x}$$

where C is a constant.

20. The differential equation $\frac{dy}{dx} + y \tan x = \cos^2 x$ is first-order linear. Let $P(x) = \tan x$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int \tan x dx} \\ &= e^{\ln(\sec x)} \\ &= \sec x \end{aligned}$$

Now multiply the differential equation by $\sec x$ and obtain

$$\sec x \frac{dy}{dx} + y \sec x \tan x = \cos x$$

The left side of the above equation is the derivative of $y \sec x$, so we can write

$$\frac{d}{dx} (y \sec x) = \cos x$$

Integrate the equation above.

$$\begin{aligned} y \sec x &= \int \cos x dx \\ &= \sin x + C \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = \sin x \cos x + C \cos x}$$

where C is a constant.

21. Given the Bernoulli equation $\frac{dy}{dx} + x^{-1}y = 3x^2y^3$, with $n = 3$, multiply the equation by y^{-3} to obtain

$$y^{-3} \frac{dy}{dx} + x^{-1}y^{-2} = 3x^2$$

Let $v = y^{-2}$, so $\frac{dv}{dx} = -2y^{-3} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{2} \frac{dv}{dx} + x^{-1}v &= 3x^2 \\ \frac{dv}{dx} - 2x^{-1}v &= -6x^2 \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{-2 \int x^{-1} dx} = e^{-2 \ln x} = e^{\ln x^{-2}} = x^{-2}$$

Now multiply the differential equation by x^{-2} and obtain

$$x^{-2} \frac{dv}{dx} - 2x^{-3}v = -6$$

The left side of the above equation is the derivative of $x^{-2}v$, so we can write

$$\frac{d}{dx} (x^{-2}v) = -6$$

Integrate the equation above.

$$\begin{aligned} x^{-2}v &= -\int 6 dx \\ &= -6x + C \end{aligned}$$

Solve for v .

$$v = -6x^3 + Cx^2$$

Using $v = y^{-2}$, rewrite the solution in terms of x and y .

$$\begin{aligned} y^{-2} &= -6x^3 + Cx^2 \\ y^2 &= \frac{1}{-6x^3 + Cx^2} \\ y &= \pm \sqrt{\frac{1}{-6x^3 + Cx^2}} \\ y &= \pm \frac{1}{\sqrt{x^2(C - 6x)}} \\ y &= \pm \frac{1}{x\sqrt{C - 6x}} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \pm \frac{1}{x\sqrt{C - 6x}}}$$

22. Given the Bernoulli equation $\frac{dy}{dx} + x^{-1}y = \frac{2}{3}x^2y^4$, with $n = 4$, multiply the equation by y^{-4} to obtain

$$y^{-4}\frac{dy}{dx} + x^{-1}y^{-3} = \frac{2}{3}x^2$$

Let $v = y^{-3}$, so $\frac{dv}{dx} = -3y^{-4}\frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{3}\frac{dv}{dx} + x^{-1}v &= \frac{2}{3}x^2 \\ \frac{dv}{dx} - 3x^{-1}v &= -2x^2 \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{-3\int x^{-1}dx} = e^{-3\ln x} = e^{\ln x^{-3}} = x^{-3}$$

Now multiply the differential equation by x^{-3} and obtain

$$x^{-3}\frac{dv}{dx} - 3x^{-4}v = -2x^{-1}$$

The left side of the above equation is the derivative of $x^{-3}v$, so we can write

$$\frac{d}{dx}(x^{-3}v) = -2x^{-1}$$

Integrate the equation above.

$$\begin{aligned} x^{-3}v &= -2\int x^{-1}dx \\ x^{-3}v &= -2\ln|x| + C \\ v &= -2x^3\ln|x| + Cx^3 \end{aligned}$$

Using $v = y^{-3}$, rewrite the solution in terms of x and y , and solve for y .

$$\begin{aligned} y^{-3} &= -2x^3\ln|x| + Cx^3 \\ y^3 &= \frac{1}{-2x^3\ln|x| + Cx^3} \\ y &= \frac{1}{\sqrt[3]{-2x^3\ln|x| + Cx^3}} \end{aligned}$$

The general solution of the differential equation is

$$y = \frac{1}{\sqrt[3]{-2x^3 \ln |x| + Cx^3}}$$

23. Given the Bernoulli equation $\frac{dy}{dx} + 2xy = xy^4$, with $n = 4$, multiply the equation by y^{-4} to obtain

$$y^{-4} \frac{dy}{dx} + 2xy^{-3} = x$$

Let $v = y^{-3}$, so $\frac{dv}{dx} = -3y^{-4} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{3} \frac{dv}{dx} + 2xv &= x \\ \frac{dv}{dx} - 6xv &= -3x \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{-6 \int x dx} = e^{-3x^2}$$

Now multiply the differential equation by e^{-3x^2} and obtain

$$e^{-3x^2} \frac{dv}{dx} - 6xe^{-3x^2} v = -3xe^{-3x^2}$$

The left side of the above equation is the derivative of $e^{-3x^2} v$, so we can write

$$\frac{d}{dx} (e^{-3x^2} v) = -3xe^{-3x^2}$$

Integrate the equation above.

$$\begin{aligned} e^{-3x^2} v &= - \int 3xe^{-3x^2} dx \quad \text{Use } u = e^{-3x^2} \\ e^{-3x^2} v &= \frac{1}{2} e^{-3x^2} + C_1 \\ v &= \frac{1}{2} + C_1 e^{3x^2} \end{aligned}$$

Using $v = y^{-3}$, rewrite the solution in terms of x and y , and solve for y .

$$\begin{aligned} y^{-3} &= 0.5 + C_1 e^{3x^2} \\ y^3 &= \frac{1}{0.5 + C_1 e^{3x^2}} \\ y &= \sqrt[3]{\frac{1}{0.5 + C_1 e^{3x^2}}} \\ y &= \sqrt[3]{\frac{2}{1 + 2C_1 e^{3x^2}}} \\ y &= \sqrt[3]{\frac{2}{1 + C e^{3x^2}}} \end{aligned}$$

The general solution of the differential equation is

$$y = \sqrt[3]{\frac{2}{1 + C e^{3x^2}}}$$

24. Given the Bernoulli equation $\frac{dy}{dx} + \frac{1}{x}y = 3xy^3$, with $n = 3$, multiply the equation by y^{-3} to obtain

$$y^{-3} \frac{dy}{dx} + \frac{1}{x} y^{-2} = 3x$$

Let $v = y^{-2}$, so $\frac{dv}{dx} = -2y^{-3} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{2} \frac{dv}{dx} + \frac{1}{x} v &= 3x \\ \frac{dv}{dx} - 2x^{-1} v &= -6x \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{-\int 2x^{-1} dx} = e^{-2 \ln x} = e^{\ln x^{-2}} = x^{-2}$$

Now multiply the differential equation by x^{-2} and obtain

$$x^{-2} \frac{dv}{dx} - 2x^{-3} v = -6x^{-1}$$

The left side of the above equation is the derivative of $x^{-2}v$, so we can write

$$\frac{d}{dx} (x^{-2}v) = -6x^{-1}$$

Integrate the equation above.

$$\begin{aligned} x^{-2}v &= -\int 6x^{-1} dx \\ x^{-2}v &= -6 \ln |x| + C \\ v &= -6x^2 \ln |x| + Cx^2 \end{aligned}$$

Using $v = y^{-2}$, rewrite the solution in terms of x and y .

$$\begin{aligned} y^{-2} &= -6x^2 \ln |x| + Cx^2 \\ y^2 &= \frac{1}{-6x^2 \ln |x| + Cx^2} \\ y &= \pm \frac{1}{\sqrt{-6x^2 \ln |x| + Cx^2}} \\ y &= \pm \frac{1}{\sqrt{x^2(C - 6 \ln |x|)}} \\ y &= \pm \frac{1}{x\sqrt{C - 6 \ln |x|}} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \pm \frac{1}{x\sqrt{C - 6 \ln |x|}}}$$

25. Given the Bernoulli equation $\frac{dy}{dx} + \frac{1}{x}y = 3xy^{1/3}$, with $n = \frac{1}{3}$, multiply the equation by $y^{-1/3}$ to obtain

$$y^{-1/3} \frac{dy}{dx} + \frac{1}{x} y^{2/3} = 3x$$

Let $v = y^{2/3}$, so $\frac{dv}{dx} = \frac{2}{3}y^{-1/3}\frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned}\frac{3}{2}\frac{dv}{dx} + \frac{1}{x}v &= 3x \\ \frac{dv}{dx} + \frac{2}{3x}v &= 2x\end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{\int (2/3) \frac{1}{x} dx} = e^{(2/3) \ln x} = e^{\ln x^{2/3}} = x^{2/3}$$

Now multiply the differential equation by $x^{2/3}$ and obtain

$$x^{2/3}\frac{dv}{dx} + \frac{2}{3}x^{-1/3}v = 2x^{5/3}$$

The left side of the above equation is the derivative of $x^{2/3}v$, so we can write

$$\frac{d}{dx}(x^{2/3}v) = 2x^{5/3}$$

Integrate the equation above.

$$\begin{aligned}x^{2/3}v &= \int 2x^{5/3} dx \\ x^{2/3}v &= \frac{3}{4}x^{8/3} + C \\ v &= \frac{3}{4}x^2 + Cx^{-2/3}\end{aligned}$$

Using $v = y^{2/3}$, rewrite the solution in terms of x and y . The general solution of the differential equation is

$$\boxed{y^{2/3} = \frac{3}{4}x^2 + Cx^{-2/3}}$$

26. Given the Bernoulli equation $\frac{dy}{dx} + \frac{4y}{x} = xy^{1/2}$, with $n = \frac{1}{2}$, multiply the equation by $y^{-1/2}$ to obtain

$$y^{-1/2}\frac{dy}{dx} + 4x^{-1}y^{1/2} = x$$

Let $v = y^{1/2}$, so $\frac{dv}{dx} = \frac{1}{2}y^{-1/2}\frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned}2\frac{dv}{dx} + 4x^{-1}v &= x \\ \frac{dv}{dx} + 2x^{-1}v &= \frac{1}{2}x\end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{\int 2x^{-1} dx} = e^{2 \ln x} = e^{\ln x^2} = x^2$$

Now multiply the differential equation by x^2 and obtain

$$x^2\frac{dv}{dx} + 2xv = \frac{1}{2}x^3$$

The left side of the above equation is the derivative of x^2v , so we can write

$$\frac{d}{dx}(x^2v) = \frac{1}{2}x^3$$

Integrate the equation above.

$$\begin{aligned}x^2v &= \int \frac{1}{2}x^3 dx \\x^2v &= \frac{1}{8}x^4 + C \\v &= \frac{1}{8}x^2 + Cx^{-2}\end{aligned}$$

Using $v = y^{1/2}$, rewrite the solution in terms of x and y , and solve for y .

$$\begin{aligned}y^{1/2} &= \frac{1}{8}x^2 + Cx^{-2} \\y &= \left(\frac{1}{8}x^2 + Cx^{-2}\right)^2\end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \left(\frac{1}{8}x^2 + Cx^{-2}\right)^2}$$

Applications and Extensions

27. Write the differential equation $x \frac{dy}{dx} - y = x^2e^x$ in the form

$$\frac{dy}{dx} - \frac{y}{x} = xe^x$$

This is a first-order linear differential equation. Let $P(x) = -\frac{1}{x}$. The integrating factor is

$$\begin{aligned}e^{\int P(x) dx} &= \exp \left[-\int \frac{1}{x} dx \right] \\&= \exp [-\ln x] \\&= \exp [\ln x^{-1}] \\&= x^{-1}\end{aligned}$$

Now multiply the differential equation by x^{-1} and obtain

$$x^{-1} \frac{dy}{dx} - x^{-2}y = e^x$$

The left side of the above equation is the derivative of $x^{-1}y$, so we can write

$$\frac{d}{dx} (x^{-1}y) = e^x$$

Integrate the equation above.

$$\begin{aligned}x^{-1}y &= \int e^x dx \\&= e^x + C\end{aligned}$$

Solve for y . The general solution of the differential equation is

$$\boxed{y = x(e^x + C)}$$

where C is a constant.

28. Write the differential equation $\frac{dy}{dx} = \frac{y}{x - y^2}$ in the form

$$y \, dx + (y^2 - x) \, dy = 0$$

Let $M = y$ and $N = y^2 - x$. Since $\frac{\partial M}{\partial y} = 1$ and $\frac{\partial N}{\partial x} = -1$, then

$$\frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{M} = -\frac{2}{y}$$

is a function of y only (see Section 3, Problem 27). Let

$$u(y) = e^{\int -\frac{2}{y} \, dy} = e^{-2 \ln(y)} = e^{\ln(y^{-2})} = y^{-2} = \frac{1}{y^2}$$

Multiply the differential equation by the integrating factor $u(y)$. Then the equation

$$\frac{1}{y} \, dx + \left(1 - \frac{x}{y^2}\right) \, dy = 0$$

is exact. Let $M_1 = \frac{1}{y}$ and $N_1 = 1 - \frac{x}{y^2}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int \frac{1}{y} \, dx = \frac{x}{y} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[\frac{x}{y} + B(y) \right] = -\frac{x}{y^2} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N_1 \\ -\frac{x}{y^2} + \frac{\partial B}{\partial y} &= 1 - \frac{x}{y^2} \\ \frac{\partial B}{\partial y} &= 1 \end{aligned}$$

Now we integrate $\frac{dB}{dy} = 1$ with respect to y .

$$B(y) = \int 1 \, dy = y + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = \frac{x}{y} + y + C$$

The general solution of the differential equation is

$$\boxed{\frac{x}{y} + y + C = 0}$$

where C is a constant.

29. Given the differential equation $dx + (2x - y^2) dy = 0$, let $M = 1$ and $N = 2x - y^2$. Since $\frac{\partial M}{\partial y} = 0$ and $\frac{\partial N}{\partial x} = 2$, then

$$\frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{M} = 2$$

is a function of y only (see Section 3, Problem 27). Let

$$u(y) = e^{[2 dy]} = e^{2y}$$

Then the equation

$$e^{2y} dx + e^{2y}(2x - y^2) dy = 0$$

is exact. Let $M_1 = e^{2y}$ and $N_1 = e^{2y}(2x - y^2) = 2xe^{2y} - y^2e^{2y}$. Find f by integrating $\frac{\partial f}{\partial x} = M_1$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int e^{2y} dx = xe^{2y} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [xe^{2y} + B(y)] = 2xe^{2y} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N_1$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N_1 \\ 2xe^{2y} + \frac{\partial B}{\partial y} &= 2xe^{2y} - y^2e^{2y} \\ \frac{\partial B}{\partial y} &= -y^2e^{2y} \end{aligned}$$

Now we integrate $\frac{dB}{dy} = -y^2e^{2y}$ with respect to y , using integration by parts twice.

$$B(y) = - \int y^2 e^{2y} dy = \left(-\frac{1}{2}y^2 + \frac{1}{2}y - \frac{1}{4} \right) e^{2y} + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = \left(x - \frac{1}{2}y^2 + \frac{1}{2}y - \frac{1}{4} \right) e^{2y} + C$$

The general solution of the differential equation is

$$\left(x - \frac{1}{2}y^2 + \frac{1}{2}y - \frac{1}{4} \right) e^{2y} + C = 0$$

or

$$\boxed{x - \frac{1}{2}y^2 + \frac{1}{2}y - \frac{1}{4} + Ce^{-2y} = 0}$$

where C is a constant.

30. Consider the differential equation $(2x + y) dx - x dy = 0$. Both $2x + y$ and $-x$ are homogeneous of degree 1. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}(2x + xv) dx - x(x dv + v dx) &= 0 \\ 2x dx - x^2 dv &= 0 \\ \frac{2}{x} dx - dv &= 0 \quad \text{when } x \neq 0 \\ \int \frac{2}{x} dx - \int dv &= 0 \\ 2 \ln |x| - v + C &= 0 \\ 2 \ln |x| - \frac{y}{x} + C &= 0 \\ 2x \ln |x| - y + Cx &= 0 \\ y &= 2x \ln |x| + Cx\end{aligned}$$

Then the general solution is $\boxed{y = 2x \ln |x| + Cx}$, where C is a constant.

31. Write the differential equation $\cos x \frac{dy}{dx} + y = \sec x$ in the form

$$\frac{dy}{dx} + y \sec x = \sec^2 x$$

The differential equation is first-order linear. Let $P(x) = \sec x$. The integrating factor is

$$\begin{aligned}e^{\int P(x) dx} &= e^{\int \sec x dx} \\ &= e^{\ln(\sec x + \tan x)} \\ &= \sec x + \tan x\end{aligned}$$

Now multiply the differential equation by $\sec x + \tan x$ and obtain

$$(\sec x + \tan x) \frac{dy}{dx} + y(\sec^2 x + \sec x \tan x) = \sec^3 x + \sec^2 x \tan x$$

The left side of the above equation is the derivative of $(\sec x + \tan x)y$, so we can write

$$\frac{d}{dx} ((\sec x + \tan x)y) = \sec^3 x + \sec^2 x \tan x$$

Integrate the equation above.

$$(\sec x + \tan x)y = \int (\sec^3 x + \sec^2 x \tan x) dx$$

The first integral can be done using integration by parts. Let $u = \sec x$ and $dv = \sec^2 x dx$. Then

$$\begin{aligned}\int \sec^3 x dx &= \sec x \tan x - \int \sec x \tan^2 x dx \\ \int \sec^3 x dx &= \sec x \tan x - \int \sec x (\sec^2 x - 1) dx \\ \int \sec^3 x dx &= \sec x \tan x - \int \sec^3 x dx + \int \sec x dx \\ 2 \int \sec^3 x dx &= \sec x \tan x + \int \sec x dx \\ 2 \int \sec^3 x dx &= \sec x \tan x + \ln |\sec x + \tan x| \\ \int \sec^3 x dx &= \frac{1}{2} \sec x \tan x + \frac{1}{2} \ln |\sec x + \tan x|\end{aligned}$$

The second integral can be done using the substitution $u = \tan x$.

$$\begin{aligned}
 (\sec x + \tan x)y &= \int (\sec^3 x + \sec^2 x \tan x) dx \\
 &= \frac{1}{2} \sec x \tan x + \frac{1}{2} \ln |\sec x + \tan x| + \frac{1}{2} \tan^2 x + C_1 \\
 &= \frac{\sec x \tan x + \ln |\sec x + \tan x| + \tan^2 x + C}{2} \quad \text{where } C = 2C_1
 \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{\sec x \tan x + \ln |\sec x + \tan x| + \tan^2 x + C}{2(\sec x + \tan x)}$$

where C is a constant.

32. Write the differential equation $(1 + x^2) \frac{dy}{dx} + xy = x^3$ in the form

$$\frac{dy}{dx} + \frac{x}{x^2 + 1}y = \frac{x^3}{x^2 + 1}$$

The differential equation is first-order linear. Let $P(x) = \frac{x}{x^2 + 1}$. The integrating factor is

$$\begin{aligned}
 e^{\int P(x) dx} &= \exp \left[\int \frac{x}{x^2 + 1} dx \right] \\
 &= \exp \left[\frac{1}{2} \ln(x^2 + 1) \right] \\
 &= \exp \left[\ln(\sqrt{x^2 + 1}) \right] \\
 &= \sqrt{x^2 + 1}
 \end{aligned}$$

Now multiply the differential equation by $\sqrt{x^2 + 1}$ and obtain

$$\sqrt{x^2 + 1} \frac{dy}{dx} + \frac{x}{\sqrt{x^2 + 1}}y = \frac{x^3}{\sqrt{x^2 + 1}}$$

The left side of the above equation is the derivative of $\sqrt{x^2 + 1}y$, so we can write

$$\frac{d}{dx} \left(\sqrt{x^2 + 1}y \right) = \frac{x^3}{\sqrt{x^2 + 1}}$$

Integrate the equation above.

$$\begin{aligned}
 \sqrt{x^2 + 1}y &= \int \frac{x^3}{\sqrt{x^2 + 1}} dx \quad \text{Let } u = x^2 + 1 \\
 &= \int \frac{u - 1}{2\sqrt{u}} du \\
 &= \int \left(\frac{1}{2}u^{1/2} - \frac{1}{2}u^{-1/2} \right) du \\
 &= \frac{1}{3}u^{3/2} - u^{1/2} + C \\
 &= \frac{1}{3}(x^2 + 1)^{3/2} - (x^2 + 1)^{1/2} + C
 \end{aligned}$$

Solve for y . The general solution of the differential equation is

$$y = \frac{1}{3}x^2 - \frac{2}{3} + \frac{C}{\sqrt{x^2 + 1}}$$

where C is a constant.

33. Write the differential equation $dy + y dx = 2xy^2 e^x dx$ in the form

$$\frac{dy}{dx} + y = 2xy^2 e^x$$

to recognize that it is a Bernoulli equation with $n = 2$. Multiply the equation by y^{-2} to obtain

$$y^{-2} \frac{dy}{dx} + y^{-1} = 2xe^x$$

Let $v = y^{-1}$, so $\frac{dv}{dx} = -y^{-2} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{dv}{dx} + v &= 2xe^x \\ \frac{dv}{dx} - v &= -2xe^x \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{\int (-1) dx} = e^{-x}$$

Now multiply the differential equation by e^{-x} and obtain

$$e^{-x} \frac{dv}{dx} - e^{-x} v = -2x$$

The left side of the above equation is the derivative of $e^{-x}v$, so we can write

$$\frac{d}{dx}(e^{-x}v) = -2x$$

Integrate the equation above.

$$\begin{aligned} e^{-x}v &= -\int 2x dx \\ e^{-x}v &= -x^2 + C \\ v &= -x^2 e^x + C e^x \end{aligned}$$

Using $v = y^{-1}$, rewrite the solution in terms of x and y , and solve for y .

$$\begin{aligned} y^{-1} &= -x^2 e^x + C e^x \\ y &= \frac{1}{-x^2 e^x + C e^x} \\ y &= \frac{1}{e^x(C - x^2)} \end{aligned}$$

The general solution of the differential equation is

$$y = \frac{1}{e^x(C - x^2)}$$

34. Write the differential equation $dx + 2xy^{-1} dy = 2x^2y^2 dy$ in the form

$$\frac{dx}{dy} + 2xy^{-1} = 2x^2y^2$$

to recognize that it is a Bernoulli equation with $n = 2$. Multiply the equation by x^{-2} to obtain

$$x^{-2} \frac{dx}{dy} + 2x^{-1}y^{-1} = 2y^2$$

Let $v = x^{-1}$, so $\frac{dv}{dy} = -x^{-2} \frac{dx}{dy}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{dv}{dy} + 2y^{-1}v &= 2y^2 \\ \frac{dv}{dy} - 2y^{-1}v &= -2y^2 \end{aligned}$$

This is a first-order linear differential equation in y and v . The integrating factor is

$$e^{-\int 2y^{-1} dy} = e^{-2 \ln y} = e^{\ln y^{-2}} = y^{-2}$$

Now multiply the differential equation by y^{-2} and obtain

$$y^{-2} \frac{dv}{dy} - 2y^{-3}v = -2$$

The left side of the above equation is the derivative of $y^{-2}v$, so we can write

$$\frac{d}{dy} (y^{-2}v) = -2$$

Integrate the equation above.

$$\begin{aligned} y^{-2}v &= \int (-2) dy \\ y^{-2}v &= -2y + C \\ v &= -2y^3 + Cy^2 \end{aligned}$$

Using $v = x^{-1}$, rewrite the solution in terms of x and y .

$$\begin{aligned} x^{-1} &= -2y^3 + Cy^2 \\ x &= \frac{1}{-2y^3 + Cy^2} \\ -2xy^3 + Cxy^2 &= 1 \end{aligned}$$

The general solution of the differential equation is

$$\boxed{2xy^3 - Cxy^2 + 1 = 0}$$

35. Write the differential equation $2 \frac{dy}{dx} - yx^{-1} = 5x^3y^3$ in the form

$$\frac{dy}{dx} - \frac{1}{2}yx^{-1} = \frac{5}{2}x^3y^3$$

to recognize that it is a Bernoulli equation with $n = 3$. Multiply the equation by y^{-3} to obtain

$$y^{-3} \frac{dy}{dx} - \frac{1}{2}x^{-1}y^{-2} = \frac{5}{2}x^3$$

Let $v = y^{-2}$, so $\frac{dv}{dx} = -2y^{-3} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{2} \frac{dv}{dx} - \frac{1}{2} x^{-1} v &= \frac{5}{2} x^3 \\ \frac{dv}{dx} + x^{-1} v &= -5x^3 \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{\int x^{-1} dx} = e^{\ln x} = x$$

Now multiply the differential equation by x and obtain

$$x \frac{dv}{dx} + v = -5x^4$$

The left side of the above equation is the derivative of xv , so we can write

$$\frac{d}{dx}(xv) = -5x^4$$

Integrate the equation above.

$$\begin{aligned} xv &= -\int 5x^4 dx \\ xv &= -x^5 + C \\ v &= \frac{C - x^5}{x} \end{aligned}$$

Using $v = y^{-2}$, rewrite the solution in terms of x and y .

$$\begin{aligned} y^{-2} &= \frac{C - x^5}{x} \\ y^2 &= \frac{x}{C - x^5} \\ y &= \pm \sqrt{\frac{x}{C - x^5}} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \pm \sqrt{\frac{x}{C - x^5}}}$$

36. Write the differential equation $dx - 2xy dy = 6x^3 y^2 e^{-2y^2} dy$ in the form

$$\frac{dx}{dy} - 2xy = 6x^3 y^2 e^{-2y^2}$$

to recognize that it is a Bernoulli equation with $n = 3$. Multiply the equation by x^{-3} to obtain

$$x^{-3} \frac{dx}{dy} - 2x^{-2} y = 6y^2 e^{-2y^2}$$

Let $v = x^{-2}$, so $\frac{dv}{dy} = -2x^{-3} \frac{dx}{dy}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{2} \frac{dv}{dy} - 2yv &= 6y^2 e^{-2y^2} \\ \frac{dv}{dy} + 4yv &= -12y^2 e^{-2y^2} \end{aligned}$$

This is a first-order linear differential equation in y and v . The integrating factor is

$$e^{\int 4y \, dy} = e^{2y^2}$$

Now multiply the differential equation by e^{2y^2} and obtain

$$e^{2y^2} \frac{dv}{dy} + 4ye^{2y^2}v = -12y^2$$

The left side of the above equation is the derivative of $e^{2y^2}v$, so we can write

$$\frac{d}{dy} (e^{2y^2}v) = -12y^2$$

Integrate the equation above.

$$\begin{aligned} e^{2y^2}v &= -\int 12y^2 \, dy \\ e^{2y^2}v &= -4y^3 + C \\ v &= (C - 4y^3)e^{-2y^2} \end{aligned}$$

Using $v = x^{-2}$, rewrite the solution in terms of x and y .

$$\begin{aligned} x^{-2} &= (C - 4y^3)e^{-2y^2} \\ x^2 &= \frac{e^{2y^2}}{C - 4y^3} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{x^2 = \frac{e^{2y^2}}{C - 4y^3}}$$

37. Write the differential equation $(x^2 + 2y^2)\frac{dx}{dy} + xy = 0$ in the form

$$(x^2 + 2y^2) \, dx + xy \, dy = 0$$

Both $x^2 + 2y^2$ and xy are homogeneous of degree 2. Let $y = xv$. Then $dy = x \, dv + v \, dx$. Substitute these into the differential equation:

$$\begin{aligned} (x^2 + 2x^2v^2) \, dx + x^2v(x \, dv + v \, dx) &= 0 \\ (x^2 + 3x^2v^2) \, dx + x^3v \, dv &= 0 \\ x^2(1 + 3v^2) \, dx + x^3v \, dv &= 0 \\ \frac{1}{x} \, dx + \frac{v}{1 + 3v^2} \, dv &= 0 \quad \text{Divide by } x^3(1 + 3v^2) \, (x \neq 0) \\ \int \frac{1}{x} \, dx + \int \frac{v}{1 + 3v^2} \, dv &= 0 \\ \ln x + \frac{1}{6} \ln(1 + 3v^2) &= C_1 \\ 6 \ln x + \ln(1 + 3v^2) &= 6C_1 \\ \ln x^6 + \ln(1 + 3v^2) &= 6C_1 \\ \ln(x^6(1 + 3v^2)) &= 6C_1 \\ x^6(1 + 3v^2) &= e^{6C_1} \quad \text{Let } C = e^{6C_1} \neq 0 \\ x^6 \left(1 + \frac{3y^2}{x^2}\right) &= C \\ x^6 + 3x^4y^2 &= C \end{aligned}$$

It can be shown that $x = 0$ is a solution, and that $x = 0$ corresponds to $C = 0$. So C can be any constant. Then the general solution is $\boxed{x^6 + 3x^4y^2 = C}$, where C is a constant.

38. Write the differential equation $(3x^2y^2 - e^yx^4y)\frac{dy}{dx} = 2xy^3$ in the form

$$\frac{dx}{dy} - \frac{3}{2}xy^{-1} = -\frac{1}{2}x^3y^{-2}e^y$$

to recognize that it is a Bernoulli equation with $n = 3$. Multiply the equation by x^{-3} to obtain

$$x^{-3}\frac{dx}{dy} - \frac{3}{2}x^{-2}y^{-1} = -\frac{1}{2}y^{-2}e^y$$

Let $v = x^{-2}$, so $\frac{dv}{dy} = -2x^{-3}\frac{dx}{dy}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{2}\frac{dv}{dy} - \frac{3}{2}y^{-1}v &= -\frac{1}{2}y^{-2}e^y \\ \frac{dv}{dy} + 3y^{-1}v &= y^{-2}e^y \end{aligned}$$

This is a first-order linear differential equation in y and v . The integrating factor is

$$e^{\int 3y^{-1} dy} = e^{3 \ln y} = e^{\ln y^3} = y^3$$

Now multiply the differential equation by y^3 and obtain

$$y^3\frac{dv}{dy} + 3y^2v = ye^y$$

The left side of the above equation is the derivative of y^3v , so we can write

$$\frac{d}{dy}(y^3v) = ye^y$$

Integrate the equation above using the technique of integration by parts.

$$\begin{aligned} y^3v &= \int ye^y dx \\ y^3v &= (y-1)e^y + C \\ v &= \frac{(y-1)e^y + C}{y^3} \end{aligned}$$

Using $v = x^{-2}$, rewrite the solution in terms of x and y .

$$\begin{aligned} x^{-2} &= \frac{(y-1)e^y + C}{y^3} \\ x^2 &= \frac{y^3}{(y-1)e^y + C} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{x^2 = \frac{y^3}{(y-1)e^y + C}}$$

39. The differential equation $\frac{dy}{dx} + y = e^{-x}$ is first-order linear. Let $P(x) = 1$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int 1 dx} \\ &= e^x \end{aligned}$$

Now multiply the differential equation by e^x and obtain

$$e^x \frac{dy}{dx} + e^x y = 1$$

The left side of the above equation is the derivative of $e^x y$, so we can write

$$\frac{d}{dx} (e^x y) = 1$$

Integrate the equation above.

$$\begin{aligned} e^x y &= \int 1 dx \\ &= x + C \end{aligned}$$

Substitute $x = 0$ and $y = 5$ to find $C = 5$. Solve for y . The particular solution of the differential equation is

$$\boxed{y = \frac{x + 5}{e^x}}$$

40. The differential equation $\frac{dy}{dx} + \frac{2y}{x} = \frac{4}{x}$ is first-order linear. Let $P(x) = \frac{2}{x}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int 2x^{-1} dx} \\ &= e^{2 \ln x} \\ &= e^{\ln x^2} \\ &= x^2 \end{aligned}$$

Now multiply the differential equation by x^2 and obtain

$$x^2 \frac{dy}{dx} + 2xy = 4x$$

The left side of the above equation is the derivative of $x^2 y$, so we can write

$$\frac{d}{dx} (x^2 y) = 4x$$

Integrate the equation above.

$$\begin{aligned} x^2 y &= \int 4x dx \\ &= 2x^2 + C \end{aligned}$$

Substitute $x = 1$ and $y = 6$ to find $C = 4$. Solve for y . The particular solution of the differential equation is

$$\boxed{y = 2 + 4x^{-2}}$$

41. The differential equation $\frac{dy}{dx} + \frac{y}{x} = e^x$ is first-order linear. Let $P(x) = \frac{1}{x}$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int x^{-1} dx} \\ &= e^{\ln x} \\ &= x \end{aligned}$$

Now multiply the differential equation by x and obtain

$$x \frac{dy}{dx} + y = xe^x$$

The left side of the above equation is the derivative of xy , so we can write

$$\frac{d}{dx}(xy) = xe^x$$

Integrate the equation above using the technique of integration by parts.

$$\begin{aligned} xy &= \int xe^x dx \\ &= xe^x - e^x + C \end{aligned}$$

Substitute $x = -1$ and $y = e^{-1}$ to find $C = e^{-1}$. Solve for y . The particular solution of the differential equation is

$$y = e^x - \frac{e^x}{x} + \frac{e^{-1}}{x}$$

42. The differential equation $\frac{dy}{dx} + y \cot x = 2 \cos x$ is first-order linear. Let $P(x) = \cot x$. The integrating factor is

$$\begin{aligned} e^{\int P(x) dx} &= e^{\int \cot x dx} \\ &= e^{\ln(\sin x)} \\ &= \sin x \end{aligned}$$

Now multiply the differential equation by $\sin x$ and obtain

$$\sin x \frac{dy}{dx} + y \cos x = 2 \sin x \cos x = \sin 2x$$

The left side of the above equation is the derivative of $y \sin x$, so we can write

$$\frac{d}{dx}(y \sin x) = \sin 2x$$

Integrate the equation above.

$$\begin{aligned} y \sin x &= \int \sin 2x dx \\ &= -\frac{1}{2} \cos 2x + C \end{aligned}$$

Substitute $x = \frac{\pi}{2}$ and $y = 3$ to find $C = \frac{5}{2}$. Solve for y . The particular solution of the differential equation is

$$y = -\frac{1}{2} \cos 2x \csc x + \frac{5}{2} \csc x$$

43. Consider the differential equation $\frac{dy}{dx} + \frac{3y}{x} = \sin x$.

(a) The general solution of the differential equation is

$$y = \frac{-x^3 \cos x + 3x^2 \sin x - 6 \sin x + 6x \cos x + C}{x^3}$$

(b) The particular solution that satisfies the boundary condition $y(\pi) = 0$ is

$$y = \frac{-x^3 \cos x + 3x^2 \sin x - 6 \sin x + 6x \cos x + 6\pi - \pi^3}{x^3}$$

(c) The graph of the particular solution over the interval $[\pi/2, 5\pi/2]$ is shown below.

44. Consider the differential equation $x \frac{dy}{dx} + 2y = \frac{5 \sin x}{x}$.

(a) The general solution of the differential equation is

$$y = \frac{C - 5 \cos x}{x^2}$$

(b) The particular solution that satisfies the boundary condition $y(\pi) = 0$ is

$$y = \frac{-5 - 5 \cos x}{x^2}$$

(c) The graph of the particular solution over the interval $[\pi/2, 5\pi/2]$ is shown below.

45. The derivative of position is velocity, that is

$$\frac{ds}{dt} = v(t) = -\frac{mg}{k} + \left(v_0 + \frac{mg}{k}\right) e^{-(k/m)t}$$

Integrate to find the position.

$$\begin{aligned} s(t) &= \int \left(-\frac{mg}{k} + \left(v_0 + \frac{mg}{k}\right) e^{-(k/m)t}\right) dt \\ &= -\frac{mg}{k}t - \frac{m}{k} \left(v_0 + \frac{mg}{k}\right) e^{-(k/m)t} + C \\ &= -\frac{mg}{k}t - \left(\frac{v_0 m}{k} + \frac{m^2 g}{k^2}\right) e^{-(k/m)t} + C \end{aligned}$$

Use $s(0) = s_0$ to find C .

$$\begin{aligned}s_0 &= 0 - \left(\frac{v_0 m}{k} + \frac{m^2 g}{k^2} \right) e^0 + C \\s_0 &= - \left(\frac{v_0 m}{k} + \frac{m^2 g}{k^2} \right) + C \\s_0 + \left(\frac{v_0 m}{k} + \frac{m^2 g}{k^2} \right) &= C\end{aligned}$$

The position of a freely falling object at any time t is

$$s(t) = s_0 - \frac{mg}{k}t + \left(\frac{v_0 m}{k} + \frac{m^2 g}{k^2} \right) \left(1 - e^{-(k/m)t} \right)$$

46. The mass of the object in grams is $m = 2000$, the initial velocity in m/s is $v_0 = 0$ (because the object is dropped from rest), the initial height in meters is 2000, the acceleration due to gravity in m/s² is $g = 9.8$, and the constant of proportionality is $k = \frac{1}{2} = 0.5$.

(a) The velocity is

$$\begin{aligned}v(t) &= -\frac{mg}{k} + \left(v_0 + \frac{mg}{k} \right) e^{-(k/m)t} \\&= -\frac{(2000)(9.8)}{0.5} + \left(0 + \frac{(2000)(9.8)}{0.5} \right) e^{-(0.5/2000)t} \\&= \boxed{-39,200 + 39,200e^{-0.00025t}}\end{aligned}$$

Note that $v \leq 0$ when $t \geq 0$. The distance the object has fallen at time t is

$$s(t) = \int_0^t |v(x)| dx = \int_0^t -v(x) dx$$

not to be confused with the height of the object. The distance s that the object has fallen at time t is

$$\begin{aligned}s(t) &= \int_0^t |v(x)| dx = \int_0^t -v(x) dx \\&= \int_0^t 39,200 - 39,200e^{-0.00025x} dx \\&= 39,200x + 156,800,000e^{0.00025x} \Big|_0^t \\&= (39,200t + 156,800,000e^{0.00025t}) - (0 + 156,800,000e^0) \\&= \boxed{-156,800,000 + 39,200t + 156,800,000e^{-0.00025t}}\end{aligned}$$

Alternatively, let $\bar{s}(t)$ represent the height of the object. Then the distance the object has fallen is $s(t) = \bar{s}(0) - \bar{s}(t)$. Using the formula found in Problem 45, the distance that the object has fallen at time t is

$$\begin{aligned}s(t) &= 2000 - \left[\bar{s}_0 - \frac{mg}{k}t + \left(\frac{v_0 m}{k} + \frac{m^2 g}{k^2} \right) \left(1 - e^{-(k/m)t} \right) \right] \\&= 2000 - \left[2000 - \frac{(2000)(9.8)}{0.5}t + \left(0 + \frac{(2000)^2(9.8)}{(0.5)^2} \right) \left(1 - e^{-(0.5/2000)t} \right) \right] \\&= -156,800,000 + 39,200t + 156,800,000e^{-0.00025t}\end{aligned}$$

(b) The limiting velocity of the object is

$$\lim_{t \rightarrow \infty} (-39,200 + 39,200e^{-0.00025t}) = \boxed{-39,200 \text{ m/s}^2}$$

(c) The object will strike Earth when it has fallen 2000m.

$$\begin{aligned} 2000 &= -156,800,000 + 39,200t + 156,800,000e^{-0.00025t} \\ t &\approx 20.22007 \end{aligned}$$

The object strikes the Earth with a velocity of $v(20.22007) = \boxed{-197.657 \text{ m/s}^2}$.

47. Let $s(t)$ and $v(t)$ represent the position and velocity of the skydiver t seconds after the initial fall, for $0 \leq t \leq 5$. The only acceleration during the free fall is due to gravity, so $a = \frac{dv}{dt} = -32$ and for $0 \leq t \leq 5$

$$\begin{aligned} v(t) &= -\int 32 \, dt \\ &= -32t + C_1 \\ &= -32t \end{aligned}$$

since her initial velocity is $v(0) = 0$. The position is

$$\begin{aligned} s(t) &= -\int 32t \, dt \\ &= -16t^2 + C_2 \\ &= -16t^2 + 10,000 \end{aligned}$$

for $0 \leq t \leq 5$ since her initial height is 10,000ft. Her velocity when the parachute is deployed is $v(5) = -160$ and her position when the parachute is deployed is $s(5) = 9600$.

Let $\bar{s}(t)$ and $\bar{v}(t)$ represent the position and velocity of the skydiver t seconds after the parachute is deployed. Then $\bar{s}_0 = \bar{s}(0) = s(5) = 9600$ and $\bar{v}_0 = \bar{v}(0) = v(5) = -160$. The constant $k = 4$ is given and the skydiver's weight gives $mg = 160$ and $m = \frac{160}{32} = 5$. Then use the formulas in Problem 45 to find

$$\begin{aligned} \bar{v}(t) &= -\frac{mg}{k} + \left(\bar{v}_0 + \frac{mg}{k}\right)e^{-(k/m)t} \\ &= -\frac{160}{4} + \left(-160 + \frac{160}{4}\right)e^{-(4/5)t} \\ &= -40 - 120e^{-0.8t} \end{aligned}$$

for $t \geq 0$ and

$$\begin{aligned} \bar{s}(t) &= \bar{s}_0 - \frac{mg}{k}t + \left(\frac{\bar{v}_0 m}{k} + \frac{m^2 g}{k^2}\right)\left(1 - e^{-(k/m)t}\right) \\ &= 9600 - \frac{160}{4}t + \left(\frac{(-160)(5)}{4} + \frac{(5)(160)}{4^2}\right)\left(1 - e^{-(4/5)t}\right) \\ &= 9450 - 40t + 150e^{-0.8t} \end{aligned}$$

for $t \geq 0$.

(a) Since $\bar{v}(4) = -40 - 120e^{-0.8(4)} \approx -44.891$, the skydiver will be falling at a rate of $\boxed{44.891 \text{ ft/sec}}$ four seconds after the parachute opens.

- (b) The skydiver lands when $\bar{s}(t) = 0$. Solve for t .

$$\begin{aligned} 0 &= 9450 - 40t + 150e^{-0.8t} \\ t &\approx 236.250 \end{aligned}$$

The skydiver lands approximately 241.250 seconds after the initial fall or 236.250 seconds after the parachute opened.

- (c) Find $\bar{v}(236.250) = -40 - 120e^{-0.8(236.250)} = -40$. The skydiver's velocity is -40ft/sec when she lands.

48. Let M denote the population, R denote the number of people who initiated the rumor, and $y = y(t)$ denote the number of people who have heard the rumor after t days. Then $M - y$ is the number of people who have not heard the rumor after t days. Let k denote the constant of proportionality. Then the differential equation

$$\frac{dy}{dt} = ky(M - y)$$

models the rate at which the rumor spreads for $t \geq 0$, and

$$y(t) = \frac{RM}{R + (M - R)e^{-kMt}}$$

models the function for $t \geq 0$. Rewrite this equation using $M = 5000$ and $R = 100$:

$$\begin{aligned} y(t) &= \frac{(100)(5000)}{100 + (5000 - 100)e^{-5000kt}} \\ &= \frac{500,000}{100 + 4900e^{-5000kt}} \end{aligned}$$

The number of people who have heard the rumor after 3 days is 500. Use $y(3) = 500$ to find k .

$$\begin{aligned} 500 &= \frac{500,000}{100 + 4900e^{-5000k(3)}} \\ 500(100 + 4900e^{-15,000k}) &= 500,000 \\ 100 + 4900e^{-15,000k} &= 1000 \\ 4900e^{-15,000k} &= 900 \\ e^{-15,000k} &= \frac{9}{49} \\ -15,000k &= \ln\left(\frac{9}{49}\right) \\ k &= -\frac{\ln(9/49)}{15,000} \end{aligned}$$

- (a) The differential equation

$$\frac{dy}{dt} = -\frac{\ln(9/49)}{15,000}y(5000 - y)$$

models the rate of the spread of the rumor for $t \geq 0$.

- (b) The solution of the differential equation is

$$y(t) = \frac{500,000}{100 + 4900e^{t \ln(9/49)/3}}$$

for $t \geq 0$.

(c) The number of people who have heard the rumor after 8 days is

$$y(8) = \frac{500,000}{100 + 4900e^{8 \ln(9/49)/3}} \approx \boxed{3259}$$

(d) To find how long it will take for half of the people to hear the rumor, solve $y(t) = 2500$ for t .

$$\begin{aligned} 2500 &= \frac{500,000}{100 + 4900e^{t \ln(9/49)/3}} \\ 2500 \left(100 + 4900e^{t \ln(9/49)/3} \right) &= 500,000 \\ 100 + 4900e^{t \ln(9/49)/3} &= 200 \\ 4900e^{t \ln(9/49)/3} &= 100 \\ e^{t \ln(9/49)/3} &= \frac{1}{49} \\ t \frac{\ln(9/49)}{3} &= \ln\left(\frac{1}{49}\right) \\ t &= \frac{3 \ln(1/49)}{\ln(9/49)} \approx 7 \end{aligned}$$

It will take about $\boxed{7 \text{ days}}$ for half of the people to hear the rumor.

49. Let $y = y(t)$ be the amount of salt in the tank at time t . Salt enters the tank at the rate of $(3 \text{ kg/L})(8 \text{ L/min}) = 24 \text{ kg/min}$. The number of gallons of liquid remains a constant 100 L, so the concentration of salt is $y/100 \text{ kg/L}$. Then the rate at which the salt exits the tank is $(y/100 \text{ kg/L})(8 \text{ L/min}) = 2y/25 \text{ kg/min}$. The mixture problem is modeled by the differential equation

$$\frac{dy}{dt} = \text{rate in} - \text{rate out} = 24 - \frac{2y}{25}$$

for $t \geq 0$. This equation is a separable differential equation and it is first-order linear differential equation. To solve it as a first-order linear differential equation, rewrite it as $\frac{dy}{dt} + \frac{2}{25}y = 24$. The integrating factor is

$$e^{\int P(t) dt} = e^{\int 2/25 dt} = e^{2t/25}$$

Multiply the differential equation by the integrating factor to obtain

$$\begin{aligned} e^{2t/25} \frac{dy}{dt} + \frac{2}{25} e^{2t/25} y &= 24e^{2t/25} \\ \frac{d}{dt} \left[e^{2t/25} y \right] &= 24e^{2t/25} \end{aligned}$$

Integrate both sides with respect to t .

$$\begin{aligned} e^{2t/25} y &= \int 24e^{2t/25} dt \\ e^{2t/25} y &= 300e^{2t/25} + C \\ y &= 300 + Ce^{-2t/25} \end{aligned}$$

The tank initially held pure water, so $y(0) = 0$, which we use to find C .

$$\begin{aligned} 0 &= 300 + Ce^0 \\ 0 &= 300 + C \\ -300 &= C \end{aligned}$$

The amount of salt in kg at time $t \geq 0$ is $y(t) = 300 - 300e^{-2t/25}$. After 5 minutes, there is $y(5) = 300 - 300e^{-2(5)/25} \approx \boxed{98.904 \text{ kg}}$ of salt in the tank. The limit of $y(t)$ as t approaches infinity is

$$\lim_{t \rightarrow \infty} (300 - 300e^{-2t/25}) = 300$$

so after a very long time there is approximately $\boxed{300 \text{ kg}}$ of salt in the tank, when the concentration of the salt in the liquid is nearly equal to the concentration of the brine flowing into the tank.

50. Let M denote the population, R denote the number of infected students initially, and $y = y(t)$ denote the number of infected students after t days. Then $M - y$ is the number of noninfected students after t days. Let k denote the constant of proportionality. Then the differential equation

$$\frac{dy}{dt} = ky(M - y)$$

models the rate at which the infection spreads for $t \geq 0$, and

$$y(t) = \frac{RM}{R + (M - R)e^{-kMt}}$$

models the function for $t \geq 0$. Rewrite this equation using $M = 10,000$ and $R = 10$:

$$\begin{aligned} y(t) &= \frac{(10)(10,000)}{10 + (10,000 - 10)e^{-10,000kt}} \\ &= \frac{100,000}{10 + 9990e^{-10,000kt}} \end{aligned}$$

The number of students infected after 10 days is 200. Use $y(10) = 200$ to find k .

$$\begin{aligned} 200 &= \frac{100,000}{10 + 9990e^{-10,000k(10)}} \\ 200(10 + 9990e^{-100,000k}) &= 100,000 \\ 10 + 9990e^{-100,000k} &= 500 \\ 9990e^{-100,000k} &= 490 \\ e^{-100,000k} &= \frac{49}{999} \\ -100,000k &= \ln\left(\frac{49}{999}\right) \\ k &= -\frac{\ln(49/999)}{100,000} \end{aligned}$$

- (a) The differential equation

$$\frac{dy}{dt} = -\frac{\ln(49/999)}{100,000}y(10,000 - y)$$

models the rate of the spread of the infection for $t \geq 0$.

- (b) The solution of the differential equation is

$$y(t) = \frac{100,000}{10 + 9990e^{t \ln(49/999)/10}}$$

for $t \geq 0$.

- (c) The number of students infected after 5 days is

$$y(5) = \frac{100,000}{10 + 9990e^{5 \ln(49/999)/10}} \approx \boxed{45}$$

- (d) To find how long it will take for 75% of the students to be infected, solve $y(t) = 7500$ for t .

$$\begin{aligned}
 7500 &= \frac{100,000}{10 + 9990e^{t \ln(49/999)/10}} \\
 7500 \left(10 + 9990e^{t \ln(49/999)/10} \right) &= 100,000 \\
 10 + 9990e^{t \ln(49/999)/10} &= \frac{40}{3} \\
 9990e^{t \ln(49/999)/10} &= \frac{10}{3} \\
 e^{t \ln(49/999)/10} &= \frac{1}{2997} \\
 t \frac{\ln(49/999)}{10} &= \ln \left(\frac{1}{2997} \right) \\
 t &= \frac{10 \ln(1/2997)}{\ln(49/999)} \approx 27
 \end{aligned}$$

It will take about 27 days for 75% of the students to become infected.

- (e) The graph of $y = y(t)$ for the first 40 days of the flu epidemic is shown.

51. Rewrite the differential equation $\frac{dP}{dt} = P(10^{-2} - 10^{-6}P)$ in the form

$$\frac{dP}{dt} = 10^{-6}P(10^4 - P)$$

to recognize it as a logistic growth problem with $k = 10^{-6}$ and $M = 10^4$.

- (a) Given an initial population of $R = P(0) = 1500$, find the solution

$$\begin{aligned}
 P(t) &= \frac{RM}{R + (M - R)e^{-kMt}} \\
 &= \frac{(1500)(10^4)}{1500 + (10000 - 1500)e^{-(10^{-6})(10^4)t}} \\
 &= \frac{15,000,000}{1500 + 8500e^{-0.01t}} \\
 &= \frac{15,000,000}{500(3 + 17e^{-0.01t})} \\
 &= \frac{30,000}{3 + 17e^{-0.01t}}
 \end{aligned}$$

The population is modeled by the function

$$P(t) = \frac{30,000}{3 + 17e^{-0.01t}}$$

for $t \geq 0$.

(b) The limiting size of the population is $M = \boxed{10,000}$. It can be verified by the limit

$$\lim_{t \rightarrow \infty} \frac{30,000}{3 + 17e^{-0.01t}} = \frac{30,000}{3} = 10,000$$

(c) To find when the population will equal one-half of the limiting value, solve $P(t) = 5000$.

$$\begin{aligned} 5000 &= \frac{30,000}{3 + 17e^{-0.01t}} \\ 5000(3 + 17e^{-0.01t}) &= 30,000 \\ 3 + 17e^{-0.01t} &= 6 \\ 17e^{-0.01t} &= 3 \\ e^{-0.01t} &= \frac{3}{17} \\ -0.01t &= \ln\left(\frac{3}{17}\right) \\ t &= -100 \ln\left(\frac{3}{17}\right) \approx 173 \end{aligned}$$

The population will be equal to one-half of the limiting value in approximately $\boxed{173 \text{ months}}$.

(d) The graph of the predicted population for $0 \leq t \leq 600$ (50 years) is shown.

52. Assuming E , R , and L are constants, the differential equation

$$\frac{dI}{dt} + \frac{R}{L}I = \frac{E}{L}$$

is a first-order linear differential equation. The integrating factor is

$$e^{\int P(t) dt} = e^{\int R/L dt} = e^{Rt/L}$$

Multiply the differential equation by the integrating factor.

$$\begin{aligned} e^{Rt/L} \frac{dI}{dt} + \frac{R}{L} e^{Rt/L} I &= \frac{E}{L} e^{Rt/L} \\ \frac{d}{dt} [e^{Rt/L} I] &= \frac{E}{L} e^{Rt/L} \end{aligned}$$

Integrate both sides of the differential equation with respect to t .

$$\begin{aligned} e^{Rt/L} I &= \int \frac{E}{L} e^{Rt/L} dt \\ e^{Rt/L} I &= \frac{E}{R} e^{Rt/L} + C \\ I &= \frac{E}{R} + C e^{-Rt/L} \end{aligned}$$

where C is a constant. Use the initial condition $I(0) = 0$ to find C .

$$\begin{aligned} 0 &= \frac{E}{R} + Ce^0 \\ 0 &= \frac{E}{R} + C \\ -\frac{E}{R} &= C \end{aligned}$$

The particular solution of the differential equation is

$$I(t) = \frac{E}{R} - \frac{E}{R}e^{-Rt/L}$$

53. Assuming E , R , and C are constants, the differential equation

$$\frac{dq}{dt} + \frac{1}{RC}q = \frac{E}{R}$$

is a first-order linear differential equation. The integrating factor is

$$e^{\int P(t) dt} = e^{\int 1/(RC) dt} = e^{t/(RC)}$$

Multiply the differential equation by the integrating factor.

$$\begin{aligned} e^{t/(RC)} \frac{dq}{dt} + \frac{1}{RC} e^{t/(RC)} q &= \frac{E}{R} e^{t/(RC)} \\ \frac{d}{dt} [e^{t/(RC)} q] &= \frac{E}{R} e^{t/(RC)} \end{aligned}$$

Integrate both sides of the differential equation with respect to t .

$$\begin{aligned} e^{t/(RC)} q &= \int \frac{E}{R} e^{t/(RC)} dt \\ e^{t/(RC)} q &= CE e^{t/(RC)} + K \\ q &= CE + K e^{-t/(RC)} \end{aligned}$$

where K is a constant. Use the initial condition $q(0) = 0$ to find K .

$$\begin{aligned} 0 &= CE + K e^0 \\ 0 &= CE + K \\ -CE &= K \end{aligned}$$

The particular solution of the differential equation is

$$q(t) = CE - CE e^{-t/(RC)} = CE \left(1 - e^{-t/(RC)} \right)$$

54. (a) The differential equation

$$\frac{dN}{dt} = kN(N_{\max} - N)$$

is a logistic differential equation so its solution is

$$N(t) = \frac{RN_{\max}}{R + (N_{\max} - R)e^{-kN_{\max}t}}$$

for $t \geq 0$.

- (b) Given an initial population of $R = 20$ and a maximum population of $N_{\max} = 400$, the logistic function becomes

$$N(t) = \frac{(20)(400)}{20 + (400 - 20)e^{-400kt}} = \frac{8000}{20 + 380e^{-400kt}} = \frac{400}{1 + 19e^{-400kt}}$$

The population doubles in 5 years, so use $N(5) = 40$ to find k .

$$\begin{aligned} 40 &= \frac{400}{1 + 19e^{-400k(5)}} \\ 40 &= \frac{400}{1 + 19e^{-2000k}} \\ 40(1 + 19e^{-2000k}) &= 400 \\ 1 + 19e^{-2000k} &= 10 \\ 19e^{-2000k} &= 9 \\ e^{-2000k} &= \frac{9}{19} \\ -2000k &= \ln\left(\frac{9}{19}\right) \\ k &= -\frac{\ln(9/19)}{2000} \end{aligned}$$

Now the logistic function is

$$N(t) = \frac{400}{1 + 19e^{t \ln(9/19)/5}}$$

- (c) Since $N(43) = \frac{400}{1 + 19e^{43 \ln(9/19)/5}} \approx 388$, the population after 43 years as modeled will be approximately 388 fish.
- (d) The population is growing fastest when $\frac{dN}{dt}$ is at a maximum. Notice that by completing the square that the derivative equals

$$\begin{aligned} \frac{dN}{dt} &= kN(N_{\max} - N) \\ &= kNN_{\max} - kN^2 \\ &= -k\frac{N_{\max}^2}{4} + kNN_{\max} - kN^2 + k\frac{N_{\max}^2}{4} \\ &= -k\left(\frac{N_{\max}}{2} - N\right)^2 + k\frac{N_{\max}^2}{4} \end{aligned}$$

When $k > 0$ the maximum is when $\frac{N_{\max}}{2} - N = 0$ and when $k < 0$ the minimum is when $\frac{N_{\max}}{2} - N = 0$. Since $k > 0$, the maximum of the derivative and the moment when the population is growing fastest is when $N = \frac{N_{\max}}{2}$.

- (e) The graph of the predicted population $N = N(t)$ is shown.

55. (a) The differential equation

$$\frac{dN}{dt} = pN \ln \left(\frac{N_{\max}}{N} \right)$$

is separable. Separate the variables and integrate.

$$\begin{aligned} \frac{dN}{dt} &= pN \ln \left(\frac{N_{\max}}{N} \right) \\ \frac{dN}{dt} &= pN (\ln N_{\max} - \ln N) \\ \frac{1}{N (\ln N_{\max} - \ln N)} dN &= p dt \\ \int \frac{1}{N (\ln N_{\max} - \ln N)} dN &= \int p dt \quad u = \ln N_{\max} - \ln N, \text{ so } du = -\frac{1}{N} dN \\ - \int \frac{1}{u} du &= \int p dt \\ - \ln |u| &= pt + C_1 \\ - \ln |\ln N_{\max} - \ln N| &= pt + C_1 \\ \ln |\ln N_{\max} - \ln N| &= -pt - C_1 \\ |\ln N_{\max} - \ln N| &= e^{-pt - C_1} \\ |\ln N_{\max} - \ln N| &= e^{-pt} e^{-C_1} \\ \ln N_{\max} - \ln N &= \pm e^{-pt} e^{-C_1} \\ \ln N_{\max} - \ln N &= -C e^{-pt} \\ \ln \left(\frac{N_{\max}}{N} \right) &= -C e^{-pt} \\ \frac{N_{\max}}{N} &= \exp(-C e^{-pt}) \\ \frac{N}{N_{\max}} &= \exp(C e^{-pt}) \\ N &= N_{\max} \exp(C e^{-pt}) \end{aligned}$$

The solution to the differential equation is

$$\boxed{N(t) = N_{\max} \exp(C e^{-pt})}$$

for $t \geq 0$.

- (b) Given the maximum population of $N_{\max} = 400$, the function becomes

$$N(t) = N_{\max} \exp(C e^{-pt}) = 400 \exp(C e^{-pt})$$

Use the initial population $N(0) = 20$ to find C .

$$\begin{aligned} 20 &= 400 \exp(C e^0) \\ 20 &= 400 \exp(C) \\ 0.05 &= \exp(C) \\ \ln(0.05) &= C \end{aligned}$$

Now the function is $N(t) = 400 \exp(\ln(0.05)e^{-pt})$ The population doubles in 5 years, so use

$N(5) = 40$ to find p .

$$\begin{aligned}
 40 &= 400 \exp(\ln(0.05)e^{-5p}) \\
 0.1 &= \exp(\ln(0.05)e^{-5p}) \\
 \ln(0.1) &= \ln(0.05)e^{-5p} \\
 \frac{\ln(0.1)}{\ln(0.05)} &= e^{-5p} \\
 \ln\left(\frac{\ln(0.1)}{\ln(0.05)}\right) &= -5p \\
 -\frac{1}{5} \ln\left(\frac{\ln(0.1)}{\ln(0.05)}\right) &= p
 \end{aligned}$$

With $C \approx -2.996$ and $p \approx .0526$, the particular function is

$$N(t) = 400 \exp(-2.996e^{-0.0526t})$$

- (c) Since $N(43) = 400 \exp(-2.996e^{-0.0526(43)}) \approx 293$, the population after 43 years as modeled will be approximately 293 fish.
- (d) The population is growing fastest when $\frac{dN}{dt}$ is at a maximum, which is where its derivative is zero. Find the derivative of $\frac{dN}{dt}$.

$$\begin{aligned}
 \frac{d}{dt} \left[\frac{dN}{dt} \right] &= \frac{d}{dt} \left[pN \ln\left(\frac{N_{\max}}{N}\right) \right] \\
 &= \frac{d}{dt} [pN (\ln N_{\max} - \ln N)] \\
 &= p \frac{dN}{dt} (\ln N_{\max} - \ln N) + pN \left(-\frac{1}{N} \frac{dN}{dt} \right) \\
 &= p \frac{dN}{dt} \ln\left(\frac{N_{\max}}{N}\right) - p \frac{dN}{dt} \\
 &= p \frac{dN}{dt} \left[\ln\left(\frac{N_{\max}}{N}\right) - 1 \right]
 \end{aligned}$$

Since neither p nor N' can equal zero, the derivative can only occur when

$$\ln\left(\frac{N_{\max}}{N}\right) = 1$$

Solve for N to find $N = \frac{N_{\max}}{e}$.

- (e) The graph of the predicted population $N = N(t)$ for $0 \leq t \leq 100$ is shown.

56.

57. The logistic differential equation can be rewritten by completing the square.

$$\begin{aligned}
\frac{dy}{dt} &= ky(M - y) \\
&= kMy - y^2 \\
&= -k\frac{M^2}{4} + kMy - ky^2 + k\frac{M^2}{4} \\
&= -\frac{k}{4}(M^2 - 4My + 4y^2) + k\frac{M^2}{4} \\
&= -k\left(\frac{M}{2} - y\right)^2 + k\frac{M^2}{4}
\end{aligned}$$

Recall that $k > 0$ so that $\frac{dy}{dt}$ is increasing when $y < \frac{M}{2}$ and decreasing when $y > \frac{M}{2}$. From this, it follows that the growth rate is a maximum when $y = \frac{M}{2}$.

Alternatively, find $\frac{d^2y}{dt^2}$.

$$\begin{aligned}
\frac{d^2y}{dt^2} &= \frac{d}{dt} \left[\frac{dy}{dt} \right] \\
&= \frac{d}{dt} [ky(M - y)] \\
&= \frac{d}{dt} [kMy - ky^2] \\
&= kM\frac{dy}{dt} - 2ky\frac{dy}{dt} \\
&= k\frac{dy}{dt} (M - 2y) \\
&= k[ky(M - y)] (M - 2y) \\
&= k^2y(M - y)(M - 2y)
\end{aligned}$$

When $0 < y < \frac{M}{2}$, we have $M - y > \frac{M}{2} > 0$ and $M - 2y > 0$ so the derivative of $\frac{dy}{dt}$ is positive, which means $\frac{dy}{dt}$ is increasing. When $\frac{M}{2} < y < M$, we have $0 < M - y < \frac{M}{2}$ and $M - 2y < 0$ so the derivative of $\frac{dy}{dt}$ is negative, which means $\frac{dy}{dt}$ is decreasing. From this, it follows that the growth rate is a maximum when $y = \frac{M}{2}$.

58. Separate the variables in the differential equation

$$\frac{dy}{dt} = ky(M - y)$$

and integrate.

$$\begin{aligned}
 \frac{dy}{dt} &= ky(M-y) \\
 \frac{1}{y(M-y)} dy &= k dt \\
 \int \frac{1}{y(M-y)} dy &= \int k dt \\
 \frac{1}{M} \int \left(\frac{1}{y} + \frac{1}{M-y} \right) dy &= \int k dt \\
 \int \left(\frac{1}{y} + \frac{1}{M-y} \right) dy &= \int kM dt \\
 \ln |y| - \ln |M-y| &= kMt + C_1 \\
 \ln |M-y| - \ln |y| &= -kMt - C_1 \\
 \ln \left| \frac{M-y}{y} \right| &= -kMt - C_1 \\
 \left| \frac{M-y}{y} \right| &= e^{-kMt - C_1} \\
 \left| \frac{M-y}{y} \right| &= e^{-kMt} e^{-C_1} \\
 \frac{M-y}{y} &= \pm e^{-kMt} e^{-C_1} \\
 \frac{M-y}{y} &= Ce^{-kMt} \\
 \frac{M}{y} - 1 &= Ce^{-kMt} \\
 \frac{M}{y} &= 1 + Ce^{-kMt} \\
 \frac{y}{M} &= \frac{1}{1 + Ce^{-kMt}} \\
 y &= \frac{M}{1 + Ce^{-kMt}}
 \end{aligned}$$

If we assume that the initial condition is $y(0) = R$, $0 \leq R < M$, then $R = \frac{M}{1+C}$ or $C = \frac{M-R}{R}$ and

$$y(t) = \frac{M}{1 + Ce^{-kMt}} = \frac{M}{1 + \frac{M-R}{R}e^{-kMt}} = \frac{RM}{R + (M-R)e^{-kMt}}$$

This answer matches the answer obtained with the “Bernoulli solution”.

Challenge Problem

59. Let $y = y(t)$ be the volume of carbon dioxide in cubic-feet present in the room at time t in minutes. Carbon dioxide enters the room at the rate of $(0.04\%)(5000 \text{ ft}^3/\text{min}) = 2 \text{ ft}^3/\text{min}$. The volume of air in the room remains a constant $150,000 \text{ ft}^3/\text{min}$, so the percentage of carbon dioxide is $y/150,000\%$. Then the rate at which the carbon dioxide leaves the room is $(y/150,000\%)(5000 \text{ ft}^3/\text{min}) = y/30 \text{ ft}^3/\text{min}$. The mixture problem is modeled by the differential equation

$$\frac{dy}{dt} = \text{rate in} - \text{rate out} = 2 - \frac{y}{30}$$

for $t \geq 0$. This equation is a separable differential equation and it is first-order linear differential equation. To solve it as a first-order linear differential equation, rewrite it as $\frac{dy}{dt} + \frac{1}{30}y = 2$. The

integrating factor is

$$e^{\int P(t) dt} = e^{\int 1/30 dt} = e^{t/30}$$

Multiply the differential equation by the integrating factor to obtain

$$\begin{aligned} e^{t/30} \frac{dy}{dt} + \frac{1}{30} e^{t/30} y &= 2e^{t/30} \\ \frac{d}{dt} [e^{t/30} y] &= 2e^{t/30} \end{aligned}$$

Integrate both sides with respect to t .

$$\begin{aligned} e^{t/30} y &= \int 2e^{t/30} dt \\ e^{t/30} y &= 60e^{t/30} + C \\ y &= 60 + Ce^{-t/30} \end{aligned}$$

Initially, 0.3% of the air in the room initially was carbon dioxide, so $y(0) = (0.003)(150,000) = 450$, which we use to find C .

$$\begin{aligned} 450 &= 60 + Ce^0 \\ 450 &= 60 + C \\ 390 &= C \end{aligned}$$

The volume of the carbon dioxide after t minutes is $y(t) = 60 + 390e^{-t/30}$. After 1 hour, there is $y(60) = 60 + 390e^{-60/30} = 60 + 390e^{-2}$ cubic-feet of carbon dioxide in the room, so the percentage is $\frac{60 + 390e^{-2}}{150,000} \approx \boxed{0.0752\%}$. After 2 hours, there is $y(120) = 60 + 390e^{-120/30} = 60 + 390e^{-4}$ cubic-feet of carbon dioxide in the room, so the percentage is $\frac{60 + 390e^{-4}}{150,000} \approx \boxed{0.0448\%}$.

60. Assume that the percentage of cash that comes into the bank each day that consists of new bills is the same as the percentage in the general circulation. Let $y = y(t)$ be the amount of new currency in circulation in millions of dollars t days after the new currency is first issued. Of the \$10 million that comes into the federal bank each day, a portion of it, namely $((y \text{ \$ million})/(\$3 \text{ billion}))(\$10 \text{ million}) = y/300$ million \$, consists of new currency. So the federal bank replaces $10 - y/300$ in \$ million of the old currency each day.

$$\frac{dy}{dt} = \text{rate in} - \text{rate out} = 10 - \frac{y}{300}$$

for $t \geq 0$. This equation is a separable differential equation and it is first-order linear differential equation. To solve it as a first-order linear differential equation, rewrite it as $\frac{dy}{dt} + \frac{1}{300}y = 10$. The integrating factor is

$$e^{\int P(t) dt} = e^{\int 1/300 dt} = e^{t/300}$$

Multiply the differential equation by the integrating factor to obtain

$$\begin{aligned} e^{t/300} \frac{dy}{dt} + \frac{1}{300} e^{t/300} y &= 10e^{t/300} \\ \frac{d}{dt} [e^{t/300} y] &= 10e^{t/300} \end{aligned}$$

Integrate both sides with respect to t .

$$\begin{aligned} e^{t/300} y &= \int 10e^{t/300} dt \\ e^{t/300} y &= 3000e^{t/300} + C \\ y &= 3000 + Ce^{-t/300} \end{aligned}$$

When the new currency was first issued, there was none of the new currency in circulation, so $y(0) = 0$, which we use to find C .

$$\begin{aligned} 0 &= 3000 + Ce^0 \\ 0 &= 3000 + C \\ -3000 &= C \end{aligned}$$

The amount of new currency in circulation in millions of dollars after t days is $y(t) = 3000 - 3000e^{-t/300}$. To find how long it will take for the currency to be 95% new, solve $y(t) = (0.95)(3000) = 2850$.

$$\begin{aligned} 2850 &= 3000 - 3000e^{-t/300} \\ -150 &= -3000e^{-t/300} \\ 0.05 &= e^{-t/300} \\ \ln(0.05) &= -\frac{t}{300} \\ -300 \ln(0.05) &= t \\ 899 &\approx t \end{aligned}$$

It will take about 899 days for the currency in circulation to become 95% new.

61. Rewrite the differential equation

$$L \frac{dI}{dt} + RI = E_0 \sin(\omega t)$$

in the form

$$\frac{dI}{dt} + \frac{RI}{L} = \frac{E_0 \sin(\omega t)}{L}$$

to recognize it as a first-order linear differential equation. The integrating factor is

$$e^{\int P(t) dt} = e^{\int R/L dt} = e^{Rt/L}$$

Now multiply the differential equation by $e^{Rt/L}$ and obtain

$$e^{Rt/L} \frac{dI}{dt} + \frac{R}{L} e^{Rt/L} I = \frac{E_0}{L} \sin(\omega t) e^{Rt/L}$$

The left side of the above equation is the derivative of $e^{Rt/L} I$, so we can write

$$\frac{d}{dt} (e^{Rt/L} I) = \frac{E_0}{L} \sin(\omega t) e^{Rt/L}$$

Integrate the equation above.

$$\begin{aligned} e^{Rt/L} I &= \int \frac{E_0}{L} \sin(\omega t) e^{Rt/L} dt \\ e^{Rt/L} I &= \frac{E_0}{L} \frac{L (R \sin(\omega t) - \omega L \cos(\omega t)) e^{Rt/L}}{R^2 + \omega^2 L^2} + C \\ e^{Rt/L} I &= \frac{E_0 (R \sin(\omega t) - \omega L \cos(\omega t)) e^{Rt/L}}{R^2 + \omega^2 L^2} + C \\ I &= \frac{E_0 (R \sin(\omega t) - \omega L \cos(\omega t))}{R^2 + \omega^2 L^2} + C e^{-Rt/L} \end{aligned}$$

Use $I(0) = I_0$ to find C .

$$\begin{aligned} I_0 &= \frac{E_0 (R \sin(0) - \omega L \cos(0))}{R^2 + \omega^2 L^2} + C e^0 \\ I_0 &= \frac{-E_0 \omega L}{R^2 + \omega^2 L^2} + C \\ I_0 + \frac{E_0 \omega L}{R^2 + \omega^2 L^2} &= C \end{aligned}$$

The particular solution of the differential equation is

$$I = \frac{E_0 (R \sin(\omega t) - \omega L \cos(\omega t) + \omega L e^{-Rt/L})}{R^2 + \omega^2 L^2} + I_0 e^{-Rt/L}$$

16.5 Power Series Methods

Skill Building

1. Assume that the solution of the differential equation $y' + 3xy = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

Since $y' = -3xy$, this leads to

$$\begin{aligned} \sum_{k=1}^{\infty} k a_k x^{k-1} &= -3x \sum_{k=0}^{\infty} a_k x^k \\ \sum_{k=1}^{\infty} k a_k x^{k-1} &= \sum_{k=0}^{\infty} (-3a_k x^{k+1}) \end{aligned}$$

To obtain relationships among the coefficients, write out the terms.

$$a_1 x^0 + 2a_2 x + 3a_3 x^2 + 4a_4 x^3 + \cdots = -3a_0 x - 3a_1 x^2 - 3a_2 x^3 - 3a_3 x^4 - \cdots$$

Because the coefficients of corresponding powers of x are equal, we have

$$a_1 = 0 \quad 3a_3 = -3a_1 = 0 \quad 5a_5 = -3a_3 = 0 \quad \dots \quad (2n+1)a_{2n+1} = -3a_{2n-1} = 0$$

and

$$2a_2 = -3a_0 \quad 4a_4 = -3a_2 \quad 6a_6 = -3a_4 \quad \dots \quad 2na_{2n} = -3a_{2n-2} \quad \dots$$

Express these relationships with even subscripts recursively as

$$\begin{aligned} a_2 &= \left(-\frac{3}{2}\right) a_0 \quad a_4 = \left(-\frac{3}{2}\right) \left(\frac{1}{2}\right) a_2 = \left(-\frac{3}{2}\right)^2 \left(\frac{1}{2}\right) a_0 \quad a_6 = \left(-\frac{3}{2}\right) \left(\frac{1}{3}\right) a_4 = \left(-\frac{3}{2}\right)^3 \left(\frac{1}{3!}\right) a_0 \\ a_8 &= \left(-\frac{3}{2}\right) \left(\frac{1}{4}\right) a_6 = \left(-\frac{3}{2}\right)^4 \left(\frac{1}{4!}\right) a_0 \quad \dots \quad a_{2n} = \left(-\frac{3}{2}\right) \left(\frac{1}{n}\right) a_{2n-2} = \left(-\frac{3}{2}\right)^n \left(\frac{1}{n!}\right) a_0 \end{aligned}$$

The power series takes on the form

$$y(x) = \sum_{k=0}^{\infty} a_{2k} x^{2k} = \sum_{k=0}^{\infty} \left(-\frac{3}{2}\right)^k \left(\frac{1}{k!}\right) a_0 x^{2k} = a_0 \sum_{k=0}^{\infty} \left(-\frac{3}{2}\right)^k \frac{x^{2k}}{k!} = a_0 \sum_{k=0}^{\infty} \frac{1}{k!} \left(-\frac{3x^2}{2}\right)^k$$

which we recognize as $y(x) = a_0 e^{-3x^2/2}$. Let $C = a_0$. Then the solution to the differential equation is

$$y(x) = a_0 \sum_{k=0}^{\infty} \left(-\frac{3}{2}\right)^k \frac{x^{2k}}{k!} = C e^{-3x^2/2}$$

2. Assume that the solution of the differential equation $y' - x + 3xy = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

Since $y' = x - 3xy$, this leads to

$$\sum_{k=1}^{\infty} k a_k x^{k-1} = x - \sum_{k=0}^{\infty} 3 a_k x^{k+1}$$

To obtain relationships among the coefficients, write out the terms.

$$a_1 x^0 + 2a_2 x + 3a_3 x^2 + 4a_4 x^3 + \cdots = (1 - 3a_0)x - 3a_1 x^2 - 3a_2 x^3 - 3a_3 x^4 - \cdots$$

Because the coefficients of corresponding powers of x are equal, we have

$$a_1 = 0 \quad 3a_3 = -3a_1 = 0 \quad 5a_5 = -3a_3 = 0 \quad \dots \quad (2n+1)a_{2n+1} = -3a_{2n-1} = 0$$

and

$$\begin{aligned} 2a_2 &= 1 - 3a_0 & \text{or equivalently} & \quad a_2 = \left(-\frac{3}{2}\right) a_0 + \frac{1}{2} = \left(-\frac{3}{2}\right) \left(a_0 - \frac{1}{3}\right) \\ 4a_4 &= -3a_2 & \text{or equivalently} & \quad a_4 = \left(-\frac{3}{2}\right) \left(\frac{1}{2}\right) a_2 = \left(-\frac{3}{2}\right)^2 \left(\frac{1}{2}\right) \left(a_0 - \frac{1}{3}\right) \\ 6a_6 &= -3a_4 & \text{or equivalently} & \quad a_6 = \left(-\frac{3}{2}\right) \left(\frac{1}{3}\right) a_4 = \left(-\frac{3}{2}\right)^3 \left(\frac{1}{3!}\right) \left(a_0 - \frac{1}{3}\right) \\ 8a_8 &= -3a_6 & \text{or equivalently} & \quad a_8 = \left(-\frac{3}{2}\right) \left(\frac{1}{4}\right) a_6 = \left(-\frac{3}{2}\right)^4 \left(\frac{1}{4!}\right) \left(a_0 - \frac{1}{3}\right) \end{aligned}$$

In general

$$a_{2n} = \left(-\frac{3}{2}\right)^n \left(\frac{1}{n!}\right) \left(a_0 - \frac{1}{3}\right)$$

for $n > 0$. The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_{2k} x^{2k} \\ &= a_0 + \sum_{k=1}^{\infty} \left(-\frac{3}{2}\right)^k \left(\frac{1}{k!}\right) \left(a_0 - \frac{1}{3}\right) x^{2k} \\ &= \frac{1}{3} + \left(a_0 - \frac{1}{3}\right) + \sum_{k=1}^{\infty} \left(-\frac{3}{2}\right)^k \left(\frac{1}{k!}\right) \left(a_0 - \frac{1}{3}\right) x^{2k} \\ &= \frac{1}{3} + \sum_{k=0}^{\infty} \left(-\frac{3}{2}\right)^k \left(\frac{1}{k!}\right) \left(a_0 - \frac{1}{3}\right) x^{2k} \\ &= \frac{1}{3} + \left(a_0 - \frac{1}{3}\right) \sum_{k=0}^{\infty} \frac{1}{k!} \left(-\frac{3x^2}{2}\right)^k \end{aligned}$$

which we recognize as $y(x) = \frac{1}{3} + \left(a_0 - \frac{1}{3}\right) e^{-3x^2/2}$. Let $C = a_0 - \frac{1}{3}$. Then the solution to the differential equation is

$$y(x) = a_0 + \left(a_0 - \frac{1}{3}\right) \sum_{k=1}^{\infty} \left(-\frac{3}{2}\right)^k \frac{x^{2k}}{k!} = \frac{1}{3} + C e^{-3x^2/2}$$

3. Assume that the solution of the differential equation $y'' + y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + y = 0$, this leads to

$$\sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=0}^{\infty} a_k x^k = 0$$

Change the index of summation in the power series on the right from k to $k-2$.

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [k(k-1) a_k + a_{k-2}] x^{k-2} &= 0 \end{aligned}$$

Then $n(n-1)a_n + a_{n-2} = 0$ for $n \geq 2$. Since the recursive formula skips a_{n-1} , split it up by even and odd indices: $(2n)(2n-1)a_{2n} + a_{2n-2} = 0$ and $(2n+1)(2n)a_{2n+1} + a_{2n-1} = 0$ so that

$$a_{2n} = -\frac{1}{(2n)(2n-1)} a_{2n-2} = \frac{1}{(2n)(2n-1)(2n-2)(2n-3)} a_{2n-4} = \cdots = (-1)^n \frac{1}{(2n)!} a_0$$

and $(2n)(2n-1)a_{2n} + a_{2n-2}$

$$a_{2n+1} = -\frac{1}{(2n+1)(2n)} a_{2n-1} = \frac{1}{(2n+1)(2n)(2n-1)(2n-2)} a_{2n-3} = \cdots = (-1)^n \frac{1}{(2n+1)!} a_1$$

for $n \geq 1$. The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= \sum_{k=0}^{\infty} a_{2k} x^{2k} + \sum_{k=0}^{\infty} a_{2k+1} x^{2k+1} \\ &= \sum_{k=0}^{\infty} (-1)^k \frac{1}{(2k)!} a_0 x^{2k} + \sum_{k=0}^{\infty} (-1)^k \frac{1}{(2k+1)!} a_1 x^{2k+1} \\ &= a_0 \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k}}{(2k)!} + a_1 \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k+1}}{(2k+1)!} \end{aligned}$$

which we recognize as

$$y(x) = a_0 \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k}}{(2k)!} + a_1 \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k+1}}{(2k+1)!} = a_0 \cos x + a_1 \sin x$$

4. Assume that the solution of the differential equation $y'' + xy = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + xy = 0$, this leads to

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + x \sum_{k=0}^{\infty} a_k x^k &= 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=0}^{\infty} a_k x^{k+1} &= 0 \end{aligned}$$

Change the index of summation in the power series on the right from k to $k-3$.

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=3}^{\infty} a_{k-3} x^{k-2} &= 0 \\ 2a_2 x^0 + \sum_{k=3}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=3}^{\infty} a_{k-3} x^{k-2} &= 0 \\ 2a_2 x^0 + \sum_{k=3}^{\infty} [k(k-1) a_k + a_{k-3}] x^{k-2} &= 0 \end{aligned}$$

Then $a_2 = 0$ and $n(n-1)a_n + a_{n-3} = 0$ for $n \geq 3$, which can be written as

$$a_n = -\frac{1}{n(n-1)} a_{n-3}$$

Then

$$a_3 = -\frac{1}{2 \cdot 3} a_0 \quad a_6 = -\frac{1}{5 \cdot 6} a_3 = \frac{1}{2 \cdot 3 \cdot 5 \cdot 6} a_0 \quad a_9 = -\frac{1}{8 \cdot 9} a_6 = -\frac{1}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} a_0 \quad \dots$$

and

$$a_4 = -\frac{1}{3 \cdot 4} a_1 \quad a_7 = -\frac{1}{6 \cdot 7} a_4 = \frac{1}{3 \cdot 4 \cdot 6 \cdot 7} a_1 \quad a_{10} = -\frac{1}{9 \cdot 10} a_7 = -\frac{1}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} a_1 \quad \dots$$

and

$$a_5 = -\frac{1}{4 \cdot 5} a_2 = 0 \quad a_8 = -\frac{1}{7 \cdot 8} a_5 = 0 \quad a_{11} = -\frac{1}{10 \cdot 11} a_8 = 0 \quad \dots$$

The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= \sum_{k=0}^{\infty} a_{3k} x^{3k} + \sum_{k=0}^{\infty} a_{3k+1} x^{3k+1} + \sum_{k=0}^{\infty} a_{3k+2} x^{3k+2} \\ &= a_0 \left(1 - \frac{1}{2 \cdot 3} x^3 + \frac{1}{2 \cdot 3 \cdot 5 \cdot 6} x^6 - \frac{1}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} x^9 + \dots \right) \\ &\quad + a_1 \left(x - \frac{1}{3 \cdot 4} x^4 + \frac{1}{3 \cdot 4 \cdot 6 \cdot 7} x^7 - \frac{1}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} x^{10} + \dots \right) \end{aligned}$$

The power series representation of the general solution of the equation is

$$y(x) = a_0 \left(1 - \frac{1}{2 \cdot 3} x^3 + \frac{1}{2 \cdot 3 \cdot 5 \cdot 6} x^6 - \frac{1}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} x^9 + \cdots \right) \\ + a_1 \left(x - \frac{1}{3 \cdot 4} x^4 + \frac{1}{3 \cdot 4 \cdot 6 \cdot 7} x^7 - \frac{1}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} x^{10} + \cdots \right)$$

5. Assume that the solution of the differential equation $y'' + x^2 y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + x^2 y = 0$, this leads to

$$\sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + x^2 \sum_{k=0}^{\infty} a_k x^k = 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=0}^{\infty} a_k x^{k+2} = 0$$

Change the index of summation in the power series on the right from k to $k-4$.

$$\sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=4}^{\infty} a_{k-4} x^{k-2} = 0 \\ 2a_2 x^0 + 6a_3 x + \sum_{k=4}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=4}^{\infty} a_{k-4} x^{k-2} = 0 \\ 2a_2 x^0 + 6a_3 x + \sum_{k=4}^{\infty} [k(k-1) a_k + a_{k-4}] x^{k-2} = 0$$

Then $a_2 = 0$, $a_3 = 0$ and $n(n-1)a_n + a_{n-4} = 0$ for $n \geq 4$, which can be written as

$$a_n = -\frac{1}{n(n-1)} a_{n-4}$$

Then

$$a_4 = -\frac{1}{3 \cdot 4} a_0 \quad a_8 = -\frac{1}{7 \cdot 8} a_4 = \frac{1}{3 \cdot 4 \cdot 7 \cdot 8} a_0 \quad a_{12} = -\frac{1}{11 \cdot 12} a_8 = -\frac{1}{3 \cdot 4 \cdot 7 \cdot 8 \cdot 11 \cdot 12} a_0 \quad \cdots$$

and

$$a_5 = -\frac{1}{4 \cdot 5} a_1 \quad a_9 = -\frac{1}{8 \cdot 9} a_5 = \frac{1}{4 \cdot 5 \cdot 8 \cdot 9} a_1 \quad a_{13} = -\frac{1}{12 \cdot 13} a_9 = -\frac{1}{4 \cdot 5 \cdot 8 \cdot 9 \cdot 12 \cdot 13} a_1 \quad \cdots$$

and

$$a_6 = -\frac{1}{5 \cdot 6} a_2 = 0 \quad a_{10} = -\frac{1}{9 \cdot 10} a_6 = 0 \quad a_{14} = -\frac{1}{13 \cdot 14} a_{10} = 0 \quad \cdots$$

and

$$a_7 = -\frac{1}{6 \cdot 7} a_3 = 0 \quad a_{11} = -\frac{1}{10 \cdot 11} a_7 = 0 \quad a_{15} = -\frac{1}{14 \cdot 15} a_{11} = 0 \quad \cdots$$

The power series takes on the form

$$\begin{aligned}
 y(x) &= \sum_{k=0}^{\infty} a_k x^k \\
 &= \sum_{k=0}^{\infty} a_{4k} x^{4k} + \sum_{k=0}^{\infty} a_{4k+1} x^{4k+1} + \sum_{k=0}^{\infty} a_{4k+2} x^{4k+2} + \sum_{k=0}^{\infty} a_{4k+3} x^{4k+3} \\
 &= a_0 \left(1 - \frac{1}{3 \cdot 4} x^4 + \frac{1}{3 \cdot 4 \cdot 7 \cdot 8} x^8 - \frac{1}{3 \cdot 4 \cdot 7 \cdot 8 \cdot 11 \cdot 12} x^{12} + \dots \right) \\
 &\quad + a_1 \left(x - \frac{1}{4 \cdot 5} x^5 + \frac{1}{4 \cdot 5 \cdot 8 \cdot 9} x^9 - \frac{1}{4 \cdot 5 \cdot 8 \cdot 9 \cdot 12 \cdot 13} x^{13} + \dots \right)
 \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned}
 y(x) &= a_0 \left(1 - \frac{1}{3 \cdot 4} x^4 + \frac{1}{3 \cdot 4 \cdot 7 \cdot 8} x^8 - \frac{1}{3 \cdot 4 \cdot 7 \cdot 8 \cdot 11 \cdot 12} x^{12} + \dots \right) \\
 &\quad + a_1 \left(x - \frac{1}{4 \cdot 5} x^5 + \frac{1}{4 \cdot 5 \cdot 8 \cdot 9} x^9 - \frac{1}{4 \cdot 5 \cdot 8 \cdot 9 \cdot 12 \cdot 13} x^{13} + \dots \right)
 \end{aligned}$$

6. Assume that the solution of the differential equation $y'' - 2xy = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + xy = 0$, this leads to

$$\begin{aligned}
 \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} - 2x \sum_{k=0}^{\infty} a_k x^k &= 0 \\
 \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=0}^{\infty} (-2a_k x^{k+1}) &= 0
 \end{aligned}$$

Change the index of summation in the power series on the right from k to $k-3$.

$$\begin{aligned}
 \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=3}^{\infty} (-2a_{k-3} x^{k-2}) &= 0 \\
 2a_2 x^0 + \sum_{k=3}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=3}^{\infty} (-2a_{k-3} x^{k-2}) &= 0 \\
 2a_2 x^0 + \sum_{k=3}^{\infty} [k(k-1) a_k - 2a_{k-3}] x^{k-2} &= 0
 \end{aligned}$$

Then $a_2 = 0$ and $n(n-1)a_n - 2a_{n-3} = 0$ for $n \geq 3$, which can be written as

$$a_n = \frac{2}{n(n-1)} a_{n-3}$$

Then

$$a_3 = \frac{2}{2 \cdot 3} a_0 \quad a_6 = \frac{2}{5 \cdot 6} a_3 = \frac{2^2}{2 \cdot 3 \cdot 5 \cdot 6} a_0 \quad a_9 = \frac{2}{8 \cdot 9} a_6 = \frac{2^3}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} a_0 \quad \dots$$

and

$$a_4 = \frac{2}{3 \cdot 4} a_1 \quad a_7 = \frac{2}{6 \cdot 7} a_4 = \frac{2^2}{3 \cdot 4 \cdot 6 \cdot 7} a_1 \quad a_{10} = \frac{2}{9 \cdot 10} a_7 = \frac{2^3}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} a_1 \quad \dots$$

and

$$a_5 = \frac{2}{4 \cdot 5} a_2 = 0 \quad a_8 = \frac{2}{7 \cdot 8} a_5 = 0 \quad a_{11} = \frac{2}{10 \cdot 11} a_8 = 0 \quad \dots$$

The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= \sum_{k=0}^{\infty} a_{3k} x^{3k} + \sum_{k=0}^{\infty} a_{3k+1} x^{3k+1} + \sum_{k=0}^{\infty} a_{3k+2} x^{3k+2} \\ &= a_0 \left(1 + \frac{2}{2 \cdot 3} x^3 + \frac{2^2}{2 \cdot 3 \cdot 5 \cdot 6} x^6 + \frac{2^3}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} x^9 + \dots \right) \\ &\quad + a_1 \left(x + \frac{2}{3 \cdot 4} x^4 + \frac{2^2}{3 \cdot 4 \cdot 6 \cdot 7} x^7 + \frac{2^3}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} x^{10} + \dots \right) \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned} y(x) &= a_0 \left(1 + \frac{2}{2 \cdot 3} x^3 + \frac{2^2}{2 \cdot 3 \cdot 5 \cdot 6} x^6 + \frac{2^3}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} x^9 + \dots \right) \\ &\quad + a_1 \left(x + \frac{2}{3 \cdot 4} x^4 + \frac{2^2}{3 \cdot 4 \cdot 6 \cdot 7} x^7 + \frac{2^3}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} x^{10} + \dots \right) \end{aligned}$$

7. Assume that the solution of the differential equation $y'' + x^2 y' + xy = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + x^2 y' + xy = 0$, this leads to

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + x^2 \sum_{k=1}^{\infty} k a_k x^{k-1} + x \sum_{k=0}^{\infty} a_k x^k &= 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=1}^{\infty} k a_k x^{k+1} + \sum_{k=0}^{\infty} a_k x^{k+1} &= 0 \end{aligned}$$

Change the indices of summation in the power series in the middle and on the right from k to $k-3$.

$$\begin{aligned}
 \sum_{k=2}^{\infty} k(k-1)a_k x^{k-2} + \sum_{k=4}^{\infty} (k-3)a_{k-3} x^{k-2} + \sum_{k=3}^{\infty} a_{k-3} x^{k-2} &= 0 \\
 2a_2 x^0 + \sum_{k=3}^{\infty} k(k-1)a_k x^{k-2} + \sum_{k=3}^{\infty} (k-3)a_{k-3} x^{k-2} + \sum_{k=3}^{\infty} a_{k-3} x^{k-2} &= 0 \\
 2a_2 x^0 + \sum_{k=3}^{\infty} [k(k-1)a_k + (k-3)a_{k-3} + a_{k-3}] x^{k-2} &= 0 \\
 2a_2 x^0 + \sum_{k=3}^{\infty} [k(k-1)a_k + (k-2)a_{k-3}] x^{k-2} &= 0
 \end{aligned}$$

(Notice that when $k=3$, the term $(k-3)a_{k-3}x^{k-2} = 0$, so the index of the middle sum can start at 3 rather than at 4.) Then $a_2 = 0$ and $n(n-1)a_n + (n-2)a_{n-3} = 0$ for $n \geq 3$, which can be written as

$$a_n = -\frac{n-2}{n(n-1)}a_{n-3}$$

Then

$$a_3 = -\frac{1}{2 \cdot 3}a_0 \quad a_6 = -\frac{4}{5 \cdot 6}a_3 = \frac{1 \cdot 4}{2 \cdot 3 \cdot 5 \cdot 6}a_0 \quad a_9 = -\frac{7}{8 \cdot 9}a_6 = -\frac{1 \cdot 4 \cdot 7}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9}a_0 \quad \dots$$

and

$$a_4 = -\frac{2}{3 \cdot 4}a_1 \quad a_7 = -\frac{5}{6 \cdot 7}a_4 = \frac{2 \cdot 5}{3 \cdot 4 \cdot 6 \cdot 7}a_1 \quad a_{10} = -\frac{8}{9 \cdot 10}a_7 = -\frac{2 \cdot 5 \cdot 8}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10}a_1 \quad \dots$$

and

$$a_5 = -\frac{3}{4 \cdot 5}a_2 = 0 \quad a_8 = -\frac{6}{7 \cdot 8}a_5 = 0 \quad a_{11} = -\frac{9}{10 \cdot 11}a_8 = 0 \quad \dots$$

The power series takes on the form

$$\begin{aligned}
 y(x) &= \sum_{k=0}^{\infty} a_k x^k \\
 &= \sum_{k=0}^{\infty} a_{3k} x^{3k} + \sum_{k=0}^{\infty} a_{3k+1} x^{3k+1} + \sum_{k=0}^{\infty} a_{3k+2} x^{3k+2} \\
 &= a_0 \left(1 - \frac{1}{2 \cdot 3} x^3 + \frac{1 \cdot 4}{2 \cdot 3 \cdot 5 \cdot 6} x^6 - \frac{1 \cdot 4 \cdot 7}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} x^9 + \dots \right) \\
 &\quad + a_1 \left(x - \frac{2}{3 \cdot 4} x^4 + \frac{2 \cdot 5}{3 \cdot 4 \cdot 6 \cdot 7} x^7 - \frac{2 \cdot 5 \cdot 8}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} x^{10} + \dots \right)
 \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned}
 y(x) &= a_0 \left(1 - \frac{1}{2 \cdot 3} x^3 + \frac{1 \cdot 4}{2 \cdot 3 \cdot 5 \cdot 6} x^6 - \frac{1 \cdot 4 \cdot 7}{2 \cdot 3 \cdot 5 \cdot 6 \cdot 8 \cdot 9} x^9 + \dots \right) \\
 &\quad + a_1 \left(x - \frac{2}{3 \cdot 4} x^4 + \frac{2 \cdot 5}{3 \cdot 4 \cdot 6 \cdot 7} x^7 - \frac{2 \cdot 5 \cdot 8}{3 \cdot 4 \cdot 6 \cdot 7 \cdot 9 \cdot 10} x^{10} + \dots \right)
 \end{aligned}$$

8. Assume that the solution of the differential equation $y'' + 3xy' + 3y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + 3xy' + 3y = 0$, this leads to

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + 3x \sum_{k=1}^{\infty} k a_k x^{k-1} + 3 \sum_{k=0}^{\infty} a_k x^k &= 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=1}^{\infty} 3k a_k x^k + \sum_{k=0}^{\infty} 3a_k x^k &= 0 \end{aligned}$$

Change the indices of summation in the power series in the middle and on the right from k to $k-2$.

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=3}^{\infty} 3(k-2) a_{k-2} x^{k-2} + \sum_{k=2}^{\infty} 3a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} 3(k-2) a_{k-2} x^{k-2} + \sum_{k=2}^{\infty} 3a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [k(k-1) a_k + 3(k-2) a_{k-2} + 3a_{k-2}] x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [k(k-1) a_k + (3k-3) a_{k-2}] x^{k-2} &= 0 \end{aligned}$$

(Notice that when $k=2$, the term $3(k-2)a_{k-2}x^{k-2} = 0$, so the index of the middle sum can change from 3 to 2.) Then $n(n-1)a_n + (3n-3)a_{n-2} = 0$ for $n \geq 2$, which can be written as

$$a_n = -\frac{3n-3}{n(n-1)} a_{n-2} = -\frac{3}{n} a_{n-2}$$

Then

$$a_2 = -\frac{3}{2} a_0 \quad a_4 = -\frac{3}{4} a_2 = \frac{3^2}{2 \cdot 4} a_0 \quad a_6 = -\frac{3}{6} a_4 = -\frac{3^3}{2 \cdot 4 \cdot 6} a_0 \quad \cdots$$

and

$$a_3 = -\frac{3}{3} a_1 \quad a_5 = -\frac{3}{5} a_3 = \frac{3^2}{3 \cdot 5} a_1 \quad a_7 = -\frac{3}{7} a_5 = -\frac{3^3}{3 \cdot 5 \cdot 7} a_1 \quad \cdots$$

The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= \sum_{k=0}^{\infty} a_{2k} x^{2k} + \sum_{k=0}^{\infty} a_{2k+1} x^{2k+1} \\ &= a_0 \left(1 - \frac{3}{2} x^2 + \frac{3^2}{2 \cdot 4} x^4 - \frac{3^3}{2 \cdot 4 \cdot 6} x^6 + \cdots \right) \\ &\quad + a_1 \left(x - \frac{3}{3 \cdot 4} x^3 + \frac{3^2}{3 \cdot 5} x^5 - \frac{3^3}{3 \cdot 5 \cdot 7} x^7 + \cdots \right) \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned} y(x) = & a_0 \left(1 - \frac{3}{2}x^2 + \frac{3^2}{2 \cdot 4}x^4 - \frac{3^3}{2 \cdot 4 \cdot 6}x^6 + \cdots \right) \\ & + a_1 \left(x - x^3 + \frac{3^2}{3 \cdot 5}x^5 - \frac{3^3}{3 \cdot 5 \cdot 7}x^7 + \cdots \right) \end{aligned}$$

9. Assume that the solution of the differential equation $y''' + y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

and

$$y'''(x) = \sum_{k=3}^{\infty} k(k-1)(k-2) a_k x^{k-3}$$

Since $y''' + y = 0$, this leads to

$$\sum_{k=3}^{\infty} k(k-1)(k-2) a_k x^{k-3} + \sum_{k=0}^{\infty} a_k x^k = 0$$

Change the indices of summation in the power series on the right from k to $k-3$.

$$\begin{aligned} \sum_{k=3}^{\infty} k(k-1)(k-2) a_k x^{k-3} + \sum_{k=3}^{\infty} a_{k-3} x^{k-3} &= 0 \\ \sum_{k=3}^{\infty} [k(k-1)(k-2) a_k + a_{k-3}] x^{k-3} &= 0 \end{aligned}$$

Then $n(n-1)(n-2)a_n + a_{n-3} = 0$ for $n \geq 3$, which can be written as

$$a_n = -\frac{1}{n(n-1)(n-2)} a_{n-3}$$

Then

$$a_3 = -\frac{1}{1 \cdot 2 \cdot 3} a_0 = -\frac{1}{3!} a_0 \quad a_6 = -\frac{1}{4 \cdot 5 \cdot 6} a_3 = \frac{1}{6!} a_0 \quad a_9 = -\frac{1}{7 \cdot 8 \cdot 9} a_6 = -\frac{1}{9!} a_0 \quad \cdots$$

and

$$a_4 = -\frac{1}{2 \cdot 3 \cdot 4} a_1 = -\frac{1}{4!} a_1 \quad a_7 = -\frac{1}{5 \cdot 6 \cdot 7} a_4 = \frac{1}{7!} a_1 \quad a_{10} = -\frac{1}{8 \cdot 9 \cdot 10} a_7 = -\frac{1}{10!} a_1 \quad \cdots$$

and

$$a_5 = -\frac{1}{3 \cdot 4 \cdot 5} a_2 = -\frac{1}{5!} a_2 \quad a_8 = -\frac{1}{6 \cdot 7 \cdot 8} a_5 = \frac{1}{8!} a_2 \quad a_{11} = -\frac{1}{9 \cdot 10 \cdot 11} a_8 = -\frac{1}{11!} a_2 \quad \cdots$$

The power series takes on the form

$$\begin{aligned}
 y(x) &= \sum_{k=0}^{\infty} a_k x^k \\
 &= \sum_{k=0}^{\infty} a_{3k} x^{3k} + \sum_{k=0}^{\infty} a_{3k+1} x^{3k+1} + \sum_{k=0}^{\infty} a_{3k+2} x^{3k+2} \\
 &= a_0 \left(1 - \frac{1}{3!} x^3 + \frac{1}{6!} x^6 - \frac{1}{9!} x^9 + \cdots \right) \\
 &\quad + a_1 \left(x - \frac{1}{4!} x^4 + \frac{1}{7!} x^7 - \frac{1}{10!} x^{10} + \cdots \right) \\
 &\quad + a_2 \left(x^2 - \frac{2}{5!} x^5 + \frac{2}{8!} x^8 - \frac{2}{11!} x^{11} + \cdots \right)
 \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned}
 y(x) &= a_0 \left(1 - \frac{1}{3!} x^3 + \frac{1}{6!} x^6 - \frac{1}{9!} x^9 + \cdots \right) \\
 &\quad + a_1 \left(x - \frac{1}{4!} x^4 + \frac{1}{7!} x^7 - \frac{1}{10!} x^{10} + \cdots \right) \\
 &\quad + a_2 \left(x^2 - \frac{2}{5!} x^5 + \frac{2}{8!} x^8 - \frac{2}{11!} x^{11} + \cdots \right)
 \end{aligned}$$

10. Assume that the solution of the differential equation $y''' - xy = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

and

$$y'''(x) = \sum_{k=3}^{\infty} k(k-1)(k-2) a_k x^{k-3}$$

Since $y''' - xy = 0$, this leads to

$$\begin{aligned}
 \sum_{k=3}^{\infty} k(k-1)(k-2) a_k x^{k-3} - x \sum_{k=0}^{\infty} a_k x^k &= 0 \\
 \sum_{k=3}^{\infty} k(k-1)(k-2) a_k x^{k-3} - \sum_{k=0}^{\infty} a_k x^{k+1} &= 0
 \end{aligned}$$

Change the indices of summation in the power series on the right from k to $k-4$.

$$\begin{aligned} \sum_{k=3}^{\infty} k(k-1)(k-2)a_k x^{k-3} - \sum_{k=4}^{\infty} a_{k-4} x^{k-3} &= 0 \\ 6a_3 x^0 + \sum_{k=4}^{\infty} k(k-1)(k-2)a_k x^{k-3} - \sum_{k=4}^{\infty} a_{k-4} x^{k-3} &= 0 \\ 6a_3 x^0 + \sum_{k=3}^{\infty} [k(k-1)(k-2)a_k - a_{k-4}] x^{k-3} &= 0 \end{aligned}$$

Then $a_3 = 0$ and $n(n-1)(n-2)a_n - a_{n-4} = 0$ for $n \geq 4$, which can be written as

$$a_n = \frac{1}{n(n-1)(n-2)} a_{n-4}$$

Then

$$a_4 = \frac{1}{2 \cdot 3 \cdot 4} a_0 = \frac{1}{4!} a_0 \quad a_8 = \frac{1}{6 \cdot 7 \cdot 8} a_4 = \frac{5}{8!} a_0 \quad a_{12} = \frac{1}{10 \cdot 11 \cdot 12} a_8 = \frac{5 \cdot 9}{12!} a_0 \quad \dots$$

and

$$a_5 = \frac{1}{3 \cdot 4 \cdot 5} a_1 = \frac{2}{5!} a_1 \quad a_9 = \frac{1}{7 \cdot 8 \cdot 9} a_5 = \frac{2 \cdot 6}{9!} a_1 \quad a_{13} = \frac{1}{11 \cdot 12 \cdot 13} a_9 = \frac{2 \cdot 6 \cdot 10}{13!} a_1 \quad \dots$$

and

$$a_6 = \frac{1}{4 \cdot 5 \cdot 6} a_2 = \frac{2 \cdot 3}{6!} a_2 \quad a_{10} = \frac{1}{8 \cdot 9 \cdot 10} a_6 = \frac{2 \cdot 3 \cdot 7}{10!} a_2 \quad a_{14} = \frac{1}{12 \cdot 13 \cdot 14} a_{10} = \frac{2 \cdot 3 \cdot 7 \cdot 11}{14!} a_2 \quad \dots$$

and

$$a_7 = \frac{1}{4 \cdot 5 \cdot 6} a_3 = 0 \quad a_{11} = \frac{1}{8 \cdot 9 \cdot 10} a_7 = 0 \quad a_{15} = \frac{1}{12 \cdot 13 \cdot 14} a_{11} = 0 \quad \dots$$

The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= \sum_{k=0}^{\infty} a_{3k} x^{3k} + \sum_{k=0}^{\infty} a_{3k+1} x^{3k+1} + \sum_{k=0}^{\infty} a_{3k+2} x^{3k+2} \\ &= a_0 \left(1 + \frac{1}{4!} x^4 + \frac{5}{8!} x^8 + \frac{5 \cdot 11}{12!} x^{12} + \dots \right) \\ &\quad + a_1 \left(x + \frac{2}{5!} x^5 + \frac{2 \cdot 6}{9!} x^9 + \frac{2 \cdot 6 \cdot 10}{13!} x^{13} + \dots \right) \\ &\quad + a_2 \left(x^2 + \frac{2 \cdot 3}{6!} x^6 + \frac{2 \cdot 3 \cdot 7}{10!} x^{10} + \frac{2 \cdot 3 \cdot 7 \cdot 11}{14!} x^{14} + \dots \right) \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned} y(x) &= a_0 \left(1 + \frac{1}{4!} x^4 + \frac{5}{8!} x^8 + \frac{5 \cdot 11}{12!} x^{12} + \dots \right) \\ &\quad + a_1 \left(x + \frac{2}{5!} x^5 + \frac{2 \cdot 6}{9!} x^9 + \frac{2 \cdot 6 \cdot 10}{13!} x^{13} + \dots \right) \\ &\quad + a_2 \left(x^2 + \frac{2 \cdot 3}{6!} x^6 + \frac{2 \cdot 3 \cdot 7}{10!} x^{10} + \frac{2 \cdot 3 \cdot 7 \cdot 11}{14!} x^{14} + \dots \right) \end{aligned}$$

11. Assume that the solution of the differential equation $(1 + x^2)y'' - 4xy' + 6y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $(1 + x^2)y'' - 4xy' + 6y = 0$, this leads to

$$\begin{aligned} (1 + x^2) \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} - 4x \sum_{k=1}^{\infty} k a_k x^{k-1} + 6 \sum_{k=0}^{\infty} a_k x^k &= 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} k(k-1) a_k x^k - \sum_{k=1}^{\infty} 4k a_k x^k + \sum_{k=0}^{\infty} 6a_k x^k &= 0 \end{aligned}$$

Change the indices of summation in all the power series but the first from k to $k-2$.

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=4}^{\infty} (k-2)(k-3) a_{k-2} x^{k-2} - \sum_{k=3}^{\infty} 4(k-2) a_{k-2} x^{k-2} + \sum_{k=2}^{\infty} 6a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} (k-2)(k-3) a_{k-2} x^{k-2} - \sum_{k=2}^{\infty} 4(k-2) a_{k-2} x^{k-2} + \sum_{k=2}^{\infty} 6a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [k(k-1) a_k + (k-2)(k-3) a_{k-2} - 4(k-2) a_{k-2} + 6a_{k-2}] x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [k(k-1) a_k + (k-4)(k-5) a_{k-2}] x^{k-2} &= 0 \end{aligned}$$

(The factors $(k-2)$ and $(k-3)$ allow the middle two indices to begin at 2, since the additional terms are simply zero.) Then $n(n-1)a_n + (n-4)(n-5)a_{n-2} = 0$ for $n \geq 2$, which can be written as

$$a_n = -\frac{(n-4)(n-5)}{n(n-1)} a_{n-2}$$

Then

$$a_2 = -\frac{(-2) \cdot (-3)}{1 \cdot 2} a_0 = -3a_0 \quad a_4 = -\frac{(0)(-1)}{3 \cdot 4} a_2 = 0 \quad a_6 = -\frac{2 \cdot 1}{5 \cdot 6} a_4 = 0 \quad \dots$$

and

$$a_3 = -\frac{(-1)(-2)}{2 \cdot 3} a_1 = -\frac{1}{3} a_1 \quad a_5 = -\frac{0 \cdot 1}{4 \cdot 5} a_3 = 0 \quad a_7 = -\frac{2 \cdot 3}{6 \cdot 7} a_5 = 0 \quad \dots$$

The general solution of the equation is

$$\boxed{y(x) = a_0 + a_1 x - 3a_0 x^2 - \frac{1}{3} a_1 x^3 = a_0(1 - 3x^2) + a_1 \left(x - \frac{1}{3} x^3 \right)}$$

12. Assume that the solution of the differential equation $(x^2 + 2)y'' - 3xy' + 4y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $(x^2 + 2)y'' - 3xy' + 4y = 0$, this leads to

$$\begin{aligned} (x^2 + 2) \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} - 3x \sum_{k=1}^{\infty} k a_k x^{k-1} + 4 \sum_{k=0}^{\infty} a_k x^k &= 0 \\ \sum_{k=2}^{\infty} 2k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} k(k-1) a_k x^k - \sum_{k=1}^{\infty} 3k a_k x^k + \sum_{k=0}^{\infty} 4a_k x^k &= 0 \end{aligned}$$

Change the indices of summation in all the power series but the first from k to $k-2$.

$$\begin{aligned} \sum_{k=2}^{\infty} 2k(k-1) a_k x^{k-2} + \sum_{k=4}^{\infty} (k-2)(k-3) a_{k-2} x^{k-2} - \sum_{k=3}^{\infty} 3(k-2) a_{k-2} x^{k-2} + \sum_{k=2}^{\infty} 4a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} 2k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} (k-2)(k-3) a_{k-2} x^{k-2} - \sum_{k=2}^{\infty} 3(k-2) a_{k-2} x^{k-2} + \sum_{k=2}^{\infty} 4a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [2k(k-1) a_k + (k-2)(k-3) a_{k-2} - 3(k-2) a_{k-2} + 4a_{k-2}] x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [2k(k-1) a_k + (k-4)^2 a_{k-2}] x^{k-2} &= 0 \end{aligned}$$

(The factors $(k-2)$ and $(k-3)$ allow the middle two indices to begin at 2, since the additional terms are simply zero.) Then $2n(n-1)a_n + (n-4)^2 a_{n-2} = 0$ for $n \geq 2$, which can be written as

$$a_n = -\frac{(n-4)^2}{2n(n-1)} a_{n-2}$$

Then

$$a_2 = -\frac{(-2)^2}{2 \cdot 1 \cdot 2} a_0 = -a_0 \quad a_4 = -\frac{(0)^2}{2 \cdot 3 \cdot 4} a_2 = 0 \quad a_6 = -\frac{2^2}{2 \cdot 5 \cdot 6} a_4 = 0 \quad \dots$$

and

$$a_3 = -\frac{(-1)^2}{2 \cdot 2 \cdot 3} a_1 = -\frac{1}{2(3!)} a_1 \quad a_5 = -\frac{1^2}{2 \cdot 4 \cdot 5} a_3 = \frac{1}{2^2(5!)} a_1 \quad a_7 = -\frac{3^2}{2 \cdot 6 \cdot 7} a_5 = -\frac{3^2}{2^3(7!)} a_1 \quad \dots$$

The general solution of the equation is

$$\boxed{y(x) = a_0(1 - x^2) + a_1 \left(x - \frac{1}{2(3!)} x^3 + \frac{1}{2^2(5!)} x^5 - \frac{3^2}{2^3(7!)} x^7 + \frac{3^2 5^2}{2^4(9!)} x^9 - \dots \right)}$$

13. (a) Assume that the solution of the differential equation $y'' = -xy' - y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 1$, and $y'(0) = 0$ into the differential equation to find $y''(0)$.

$$y''(0) = -(0)y'(0) - y(0) = 0 - 1 = -1$$

Now differentiate $y'' = -xy' - y$ with respect to x to find $y'''(0)$.

$$\begin{aligned} y''' &= -xy'' - 2y' \\ y'''(0) &= -(0)(-1) - 2(0) = 0 \end{aligned}$$

Now differentiate $y''' = -xy'' - 2y'$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned} y^{(4)} &= -xy''' - 3y'' \\ y^{(4)}(0) &= -(0)(0) - 3(-1) = 3 \end{aligned}$$

Now differentiate $y^{(4)} = -xy''' - 3y''$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned} y^{(5)} &= -xy^{(4)} - 4y''' \\ y^{(5)}(0) &= -(0)(3) - 4(0) = 0 \end{aligned}$$

Now differentiate $y^{(5)} = -xy^{(4)} - 4y'''$ with respect to x to find $y^{(6)}(0)$.

$$\begin{aligned} y^{(6)} &= -xy^{(5)} - 5y^{(4)} \\ y^{(6)}(0) &= -(0)(0) - 5(3) = -15 \end{aligned}$$

Now differentiate $y^{(6)} = -xy^{(5)} - 5y^{(4)}$ with respect to x to find $y^{(7)}(0)$.

$$\begin{aligned} y^{(7)} &= -xy^{(6)} - 6y^{(5)} \\ y^{(7)}(0) &= -(0)(-15) - 6(0) = 0 \end{aligned}$$

Now differentiate $y^{(7)} = -xy^{(6)} - 6y^{(5)}$ with respect to x to find $y^{(8)}(0)$.

$$\begin{aligned} y^{(8)} &= -xy^{(7)} - 7y^{(6)} \\ y^{(8)}(0) &= -(0)(0) - 7(-15) = 105 \end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 - \frac{1}{2!}x^2 + \frac{3}{4!}x^4 - \frac{15}{6!}x^6 + \frac{105}{8!}x^8 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	1.0	0.9950	0.9802	0.9560	0.9231	0.8825	0.8353	0.7827	0.7262	0.6671	0.6068

14. (a) Assume that the solution of the differential equation $y'' = 2xy' - y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 2$, and $y'(0) = 1$ into the differential equation to find $y''(0)$.

$$y''(0) = 2(0)y'(0) - y(0) = 0 - 2 = -2$$

Now differentiate $y'' = 2xy' - y$ with respect to x to find $y'''(0)$.

$$\begin{aligned} y''' &= 2xy'' + 2y' - y' \\ y''' &= 2xy'' + y' \\ y'''(0) &= 2(0)(-2) + 1 = 1 \end{aligned}$$

Now differentiate $y''' = 2xy'' + y'$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned}y^{(4)} &= 2xy''' + 2y'' + y'' \\y^{(4)} &= 2xy''' + 3y'' \\y^{(4)}(0) &= 2(0)(1) + 3(-2) = -6\end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 2 + x - \frac{2}{2!}x^2 + \frac{1}{3!}x^3 - \frac{6}{4!}x^4 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	2.0	2.0901	2.1609	2.2125	2.2443	2.2552	2.2436	2.2071	2.1429	2.0475	1.9167

15. (a) Assume that the solution of the differential equation $y'' = y \sin x$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0) + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 0$, and $y'(0) = 1$ into the differential equation to find $y''(0)$.

$$y''(0) = y(0) \sin(0) = 0$$

Now differentiate $y'' = y \sin x$ with respect to x to find $y'''(0)$.

$$\begin{aligned}y''' &= y' \sin x + y \cos x \\y'''(0) &= (1) \sin(0) + (0) \cos(0) = 0\end{aligned}$$

Now differentiate $y''' = y' \sin x + y \cos x$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned}y^{(4)} &= y'' \sin x + y' \cos x + y' \cos x - y \sin x \\y^{(4)} &= y'' \sin x + 2y' \cos x - y \sin x \\y^{(4)}(0) &= (0) \sin(0) + 2(1) \cos(0) - (0) \sin(0) = 2\end{aligned}$$

Now differentiate $y^{(4)} = y'' \sin x + 2y' \cos x - y \sin x$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned}y^{(5)} &= y''' \sin x + y'' \cos x + 2y'' \cos x - 2y' \sin x - y' \sin x - y \cos x \\y^{(5)} &= y''' \sin x + 3y'' \cos x - 3y' \sin x - y \cos x \\y^{(5)}(0) &= 0\end{aligned}$$

Now differentiate $y^{(5)} = y''' \sin x + 3y'' \cos x - 3y' \sin x - y \cos x$ with respect to x to find $y^{(6)}(0)$.

$$\begin{aligned}y^{(6)} &= y^{(4)} \sin x + y''' \cos x + 3y''' \cos x - 3y'' \sin x - 3y'' \sin x - 3y' \cos x - y' \cos x + y \sin x \\y^{(6)} &= y^{(4)} \sin x + 4y''' \cos x - 6y'' \sin x - 4y' \cos x + y \sin x \\y^{(6)}(0) &= -4\end{aligned}$$

Now differentiate $y^{(6)}$ with respect to x to find $y^{(7)}(0)$. (You may notice a pattern with the binomial coefficients.)

$$\begin{aligned}y^{(7)} &= y^{(5)} \sin x + 5y^{(4)} \cos x - 10y''' \sin x - 10y'' \cos x + 5y' \sin x + y \cos x \\y^{(7)}(0) &= 10\end{aligned}$$

Now differentiate $y^{(7)}$ with respect to x to find $y^{(8)}(0)$.

$$\begin{aligned} y^{(8)} &= y^{(6)} \sin x + 6y^{(5)} \cos x - 15y^{(4)} \sin x - 20y''' \cos x + 15y'' \sin x + 6y' \cos x - y \sin x \\ y^{(8)}(0) &= 6 \end{aligned}$$

The Maclaurin series then becomes

$$y(x) = x + \frac{2}{4!}x^4 - \frac{4}{6!}x^6 + \frac{10}{7!}x^7 + \frac{6}{8!}x^8 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0

17. (a) Assume that the solution of the differential equation $y'' = -y' - e^x y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 2$, and $y'(0) = 1$ into the differential equation to find $y''(0)$.

$$y''(0) = -y'(0) - e^0 y(0) = -3$$

Now differentiate $y'' = -y' - e^x y$ with respect to x to find $y'''(0)$.

$$\begin{aligned} y''' &= -y'' - e^x y' - e^x y \\ y'''(0) &= -(-3) - e^0(1) - e^0(2) = 0 \end{aligned}$$

Now differentiate $y''' = -y'' - e^x y' - e^x y$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned} y^{(4)} &= -y''' - e^x y'' - e^x y' - e^x y \\ y^{(4)} &= -y''' - e^x y'' - 2e^x y' - e^x y \\ y^{(4)}(0) &= -0 - e^0(-3) - 2e^0(1) - e^0(2) = -1 \end{aligned}$$

Now differentiate $y^{(4)} = -y''' - e^x y'' - 2e^x y' - e^x y$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned} y^{(5)} &= -y^{(4)} - e^x y''' - 2e^x y'' - 2e^x y' - e^x y \\ y^{(5)} &= -y^{(4)} - 3e^x y''' - 3e^x y'' - 3e^x y' - e^x y \\ y^{(5)}(0) &= -(-1) - 3e^0(0) - 3e^0(-3) - 3e^0(1) - e^0(2) = 5 \end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 2 + x - \frac{3}{2!}x^2 - \frac{1}{4!}x^4 + \frac{5}{5!}x^5 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	2.0	2.0850	2.1399	2.1648	2.1594	2.1237	2.0578	1.9620	1.8366	1.6823	1.5000

18. (a) Assume that the solution of the differential equation $y'' = -(3+x)y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 1$, and $y'(0) = 0$ into the differential equation to find $y''(0)$.

$$y''(0) = -(3+0)(1) = -3$$

Now differentiate $y'' = -(3+x)y$ with respect to x to find $y'''(0)$.

$$\begin{aligned} y''' &= -(3+x)y' - y \\ y'''(0) &= -(3+0)(0) - 1 = -1 \end{aligned}$$

Now differentiate $y''' = -(3+x)y' - y$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned} y^{(4)} &= -(3+x)y'' - y' - y' \\ y^{(4)} &= -(3+x)y'' - 2y' \\ y^{(4)}(0) &= -(3+0)(-3) - 2(0) = 9 \end{aligned}$$

Now differentiate $y^{(4)} = -(3+x)y'' - 2y'$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned} y^{(5)} &= -(3+x)y''' - y'' - 2y'' \\ y^{(5)} &= -(3+x)y''' - 3y'' \\ y^{(5)}(0) &= -(3+0)(-1) - 3(-3) = 12 \end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 - \frac{3}{2!}x^2 - \frac{1}{3!}x^3 + \frac{9}{4!}x^4 + \frac{12}{5!}x^5 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

y	1.0	0.9849	0.9393	0.8638	0.7600	0.6307	0.4804	0.3147	0.1410	-0.0314	-0.1917

19. (a) Use the solution from Problem 5 with $y(0) = a_0 = 0$ and $y'(0) = a_1 = 2$. The Maclaurin series then becomes

$$y(x) = 2x - \frac{12}{5!}x^5 + \frac{504}{9!}x^9 - \frac{55,440}{13!}x^{13} + \frac{11,642,400}{17!}x^{17} + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	0.0	0.2000	0.4000	0.5998	0.7990	0.9969	1.1922	1.3832	1.5674	1.7415	1.9014

20. (a) Assume that the solution of the differential equation $y'' = 3x^2y' - 2xy$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 1$, and $y'(0) = 1$ into the differential equation to find $y''(0)$.

$$y''(0) = 3(0)^2 - 2(0)1 = 0$$

Now differentiate $y'' = 3x^2y' - 2xy$ with respect to x to find $y'''(0)$.

$$\begin{aligned}y''' &= 3x^2y'' + 6xy' - 2xy' - 2y \\y''' &= 3x^2y'' + 4xy' - 2y \\y'''(0) &= 3(0)^2(0) + 4(0)(1) - 2(1) = -2\end{aligned}$$

Now differentiate $y''' = 3x^2y'' + 4xy' - 2y$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned}y^{(4)} &= 3x^2y''' + 6xy'' + 4xy'' + 4y' - 2y' \\y^{(4)} &= 3x^2y''' + 10xy'' + 2y' \\y^{(4)}(0) &= 3(0)^2(-2) + 10(0)(0) + 2(1) = 2\end{aligned}$$

Now differentiate $y^{(4)} = 3x^2y''' + 10xy'' + 2y'$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned}y^{(5)} &= 3x^2y^{(4)} + 6xy''' + 10xy''' + 10y'' + 2y'' \\y^{(5)} &= 3x^2y^{(4)} + 16xy''' + 12y'' \\y^{(5)}(0) &= 3(0)^2(2) + 16(0)(-2) + 12(0) = 0\end{aligned}$$

Now differentiate $y^{(5)} = 3x^2y^{(4)} + 16xy''' + 12y''$ with respect to x to find $y^{(6)}(0)$.

$$\begin{aligned}y^{(6)} &= 3x^2y^{(5)} + 6xy^{(4)} + 16xy^{(4)} + 16y''' + 12y'' \\y^{(6)} &= 3x^2y^{(5)} + 22xy^{(4)} + 28y''' \\y^{(6)}(0) &= 3(0)^2(0) + 22(0)(2) + 28(-2) = -56\end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 + x - \frac{2}{3!}x^3 + \frac{2}{4!}x^4 - \frac{56}{6!}x^6 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	1.0	1.0997	1.1975	1.2916	1.3805	1.4623	1.5352	1.5965	1.6431	1.6703	1.6722

21. (a) Assume that the solution of the differential equation $y^{(4)} = \ln(1+x)y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 1$, $y'(0) = 1$, $y''(0) = 0$, and $y'''(0) = 0$ into the differential equation to find $y^{(4)}(0)$.

$$y^{(4)}(0) = \ln(1)(1) = 0$$

Now differentiate $y^{(4)} = \ln(1+x)y$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned}y^{(5)} &= \ln(1+x)y' + (1+x)^{-1}y \\y^{(5)}(0) &= \ln(1)(1) + (1)^{-1}(1) = 1\end{aligned}$$

Now differentiate $y^{(5)} = \ln(1+x)y' + (1+x)^{-1}y$ with respect to x to find $y^{(6)}(0)$.

$$\begin{aligned}y^{(6)} &= \ln(1+x)y'' + (1+x)^{-1}y' + (1+x)^{-1}y' - (1+x)^{-2}y \\y^{(6)} &= \ln(1+x)y'' + 2(1+x)^{-1}y' - (1+x)^{-2}y \\y^{(6)}(0) &= \ln(1)(0) + 2(1)^{-1}(1) - (1)^{-2}(1) = 1\end{aligned}$$

Now differentiate $y^{(6)} = \ln(1+x)y'' + 2(1+x)^{-1}y' - (1+x)^{-2}y$ with respect to x to find $y^{(7)}(0)$.

$$\begin{aligned}y^{(7)} &= \ln(1+x)y'''' + (1+x)^{-1}y''' + 2(1+x)^{-1}y'' - 2(1+x)^{-2}y' - (1+x)^{-2}y' + 2(1+x)^{-3}y \\y^{(7)} &= \ln(1+x)y'''' + 3(1+x)^{-1}y'' - 3(1+x)^{-2}y' + 2(1+x)^{-3}y \\y^{(7)}(0) &= \ln(1)(0) + 3(1)^{-1}(0) - 3(1)^{-2}(1) + 2(1)^{-3}(1) = -1\end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 + x + \frac{1}{5!}x^5 + \frac{1}{6!}x^6 - \frac{1}{7!}x^7 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	1.0	1.1000	1.2000	1.3000	1.4001	1.5003	1.6007	1.7015	1.8031	1.9056	2.0095

22. (a) Assume that the solution of the differential equation $y''' = -4y'' - 2y' + x^3y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 1$, $y'(0) = 1$, and $y''(0) = 0$ into the differential equation to find $y'''(0)$.

$$y'''(0) = -4(0) - 2(1) + 0^3(1) = -2$$

Now differentiate $y''' = -4y'' - 2y' + x^3y$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned}y^{(4)} &= -4y''' - 2y'' + x^3y' + 3x^2y \\y^{(4)}(0) &= -4(-2) - 2(0) + 0^3(1) + 3(0)^2(1) = 8\end{aligned}$$

Now differentiate $y^{(4)} = -4y''' - 2y'' + x^3y' + 3x^2y$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned}y^{(5)} &= -4y^{(4)} - 2y''' + x^3y'' + 6x^2y' + 6xy \\y^{(5)}(0) &= -4(8) - 2(-2) + (0)^3(0) + 6(0)^2(1) + 6(0)(1) = -28\end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 + x - \frac{2}{3!}x^3 + \frac{8}{4!}x^4 - \frac{28}{5!}x^5 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	1.0	1.0997	1.1978	1.2931	1.3848	1.4719	1.5531	1.6265	1.6894	1.7379	1.7667

Applications and Extensions

23. Assume that the solution of the differential equation $y'' = -4y' - 4y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $y(0) = 1$ and $y'(0) = 2$ into the differential equation.

$$y''(0) = -4y'(0) - 4y(0) = -4(2) - 4(1) = -12$$

Now differentiate $y'' = -4y' - 4y$ with respect to x to find $y'''(0)$.

$$\begin{aligned}y''' &= -4y'' - 4y' \\y'''(0) &= -4(-12) - 4(2) = 40\end{aligned}$$

Now differentiate $y''' = -4y'' - 4y'$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned}y^{(4)} &= -4y''' - 4y'' \\y^{(4)} &= -4(40) - 4(-12) = -112\end{aligned}$$

Now differentiate $y^{(4)} = -4y''' - 4y''$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned}y^{(5)} &= -4y^{(4)} - 4y''' \\y^{(5)}(0) &= -4(-112) - 4(40) = 288\end{aligned}$$

Now differentiate $y^{(5)} = -4y^{(4)} - 4y'''$ with respect to x to find $y^{(6)}(0)$.

$$\begin{aligned}y^{(6)} &= -4y^{(5)} - 4y^{(4)} \\y^{(6)}(0) &= -4(288) - 4(-112) = -704\end{aligned}$$

Now differentiate $y^{(6)} = -4y^{(5)} - 4y^{(4)}$ with respect to x to find $y^{(7)}(0)$.

$$\begin{aligned}y^{(7)} &= -4y^{(6)} - 4y^{(5)} \\y^{(7)}(0) &= -4(-704) - 4(288) = 1664\end{aligned}$$

and so on. The Maclaurin series then becomes

$$y(x) = 1 + 2x - \frac{12}{2!}x^2 + \frac{40}{3!}x^3 - \frac{112}{4!}x^4 + \frac{288}{5!}x^5 - \frac{704}{6!}x^6 + \frac{1664}{7!}x^7 - \dots$$

(a) Let

$$y(x) \approx 1 + 2x - 6x^2 + \frac{20}{3}x^3 - \frac{14}{3}x^4 + \frac{12}{5}x^5$$

approximate the solution to the differential equation.

(b) The particular solution of the differential equation is

$$y(x) = e^{-2x} (1 + 4x)$$

(c) The graph of the two functions from parts (a) and (b) are shown.

(d) Answers will vary. The approximation appears to be less accurate as x moves away from where the Maclaurin series is centered at 0.

(e) Let

$$y(x) \approx 1 + 2x - 6x^2 + \frac{20}{3}x^3 - \frac{14}{3}x^4 + \frac{12}{5}x^5 - \frac{44}{45}x^6 + \frac{104}{315}x^7$$

approximate the solution to the differential equation.

(f) The graph of the three functions from parts (a), (b), and (e) are shown.

Answers will vary. The approximation with more terms appears to be a better approximation to the solution than the approximation with fewer terms.

24. Assume that the solution of the differential equation $y' = xy(1 - y^2)$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \cdots$$

Use a Computer Algebra System and $y(0) = 2$ to find

$$y'(0) = 0 \quad y''(0) = -6 \quad y'''(0) = 0 \quad y^{(4)}(0) = 198 \quad y^{(5)}(0) = 0$$

$$y^{(6)}(0) = -17,370 \quad y^{(7)}(0) = 0 \quad y^{(8)}(0) = 2,970,450 \quad y^{(9)}(0) = 0 \quad y^{(10)}(0) = -562,897,755$$

The Maclaurin series then becomes

$$y(x) = 2 - \frac{6}{2!}x^2 + \frac{198}{4!}x^4 - \frac{17,370}{6!}x^6 + \frac{2,970,450}{8!}x^8 - \frac{562,897,755}{10!}x^{10} \dots$$

(a) Let

$$y(x) \approx 2 - \frac{6}{2!}x^2 + \frac{198}{4!}x^4 - \frac{17,370}{6!}x^6 + \frac{2,970,450}{8!}x^8 - \frac{562,897,755}{10!}x^{10}$$

approximate the solution to the differential equation.

(b) The particular solution to the differential equation is

$$y^2 \left(1 - \frac{3}{4}e^{-x^2} \right) = 1$$

(c) The graphs of the functions are shown.

Challenge Problem

25. (a) The differential equation $\frac{du}{dt} = -ku$ is separable. Separate the variables and integrate.

$$\begin{aligned}\frac{1}{u} du &= -k dt \\ \int \frac{1}{u} du &= - \int k dt \\ \ln|u| &= -kt + C_1 \\ |u| &= e^{-kt+C_1} \\ u &= \pm e^{kt} e^{C_1} \\ u &= C e^{kt}\end{aligned}$$

The initial condition $u(0) = u_0$ gives

$$u = u_0 e^{-kt}$$

and $l = u_0 - u$ gives

$$l = u_0 (1 - e^{-kt})$$

- (b) Solve for t in $r = \frac{l}{u}$.

$$\begin{aligned}r &= \frac{l}{u} \\ r &= \frac{u_0 (1 - e^{-kt})}{u_0 e^{-kt}} \\ r &= \frac{1 - e^{-kt}}{e^{-kt}} \\ r e^{-kt} &= 1 - e^{-kt} \\ e^{-kt} + r e^{-kt} &= 1 \\ e^{-kt} (1 + r) &= 1 \\ e^{-kt} &= \frac{1}{1 + r} \\ -kt &= \ln \left(\frac{1}{1 + r} \right) \\ -kt &= -\ln(1 + r) \\ t &= \frac{1}{k} \ln(1 + r)\end{aligned}$$

Now use the Maclaurin series for $f(x) = \ln(1 + x)$ to find $f(r) = \ln(1 + r)$.

$$f(x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \dots$$

when $-1 < x \leq 1$. Since $0 < r < 1$, we have

$$t = \frac{1}{k} \ln(1 + r) = \frac{1}{k} \left(r - \frac{r^2}{2} + \frac{r^3}{3} - \dots \right) \approx \frac{r}{k}$$

- (c) Use the half-life of uranium, 4.5×10^9 years, to find k .

$$\begin{aligned}\frac{u_0}{2} &= u_0 e^{-4.5 \times 10^9 k} \\ \frac{1}{2} &= e^{-4.5 \times 10^9 k} \\ \ln \left(\frac{1}{2} \right) &= -4.5 \times 10^9 k \\ -\ln(2) &= -4.5 \times 10^9 k \\ \frac{\ln(2)}{4.5 \times 10^9} &= k\end{aligned}$$

Use this k and $r \approx 0.054$ to find the lower bound.

$$\frac{r}{k} \approx \frac{0.054}{\frac{\ln(2)}{4.5 \times 10^9}} \approx 3.506 \times 10^8$$

The lower bound for the age of the Earth's crust is $\boxed{3.506 \times 10^8 \text{ years}}$.

Review Exercises

1. The differential equation $\frac{dy}{dx} + x^2y = \sin x$ is $\boxed{\text{first-order}}$ because the highest-order derivative is the first derivative. It has degree $\boxed{1}$ because the exponent of the first derivative is 1. Since $P_0(x) = 1$, $P_1(x) = x^2$, and $Q(x) = \sin x$ are all functions of x alone and no term contains more than one derivative, the differential equation is $\boxed{\text{linear}}$.
2. The differential equation $\frac{d^2y}{dx^2} - 5\frac{dy}{dx} + 3y = xe^x$ is $\boxed{\text{second-order}}$ because the highest-order derivative is the second derivative. It has degree $\boxed{1}$ because the exponent of the first derivative is 1. Since $P_0(x) = 1$, $P_1(x) = -5$, $P_2(x) = 3$, and $Q(x) = xe^x$ are all functions of x alone and no term contains more than one derivative, the differential equation is $\boxed{\text{linear}}$.
3. The differential equation $\frac{d^3y}{dx^3} + 4x\frac{d^2y}{dx^2} + (\sin^2 x)\frac{dy}{dx} + 3y = \sin x$ is $\boxed{\text{third-order}}$ because the highest-order derivative is the third derivative. It has degree $\boxed{1}$ because the exponent of the first derivative is 1. Since $P_0(x) = 1$, $P_1(x) = 4x$, $P_2(x) = \sin^2 x$, $P_3(x) = 3$, and $Q(x) = \sin x$ are all functions of x alone and no term contains more than one derivative, the differential equation is $\boxed{\text{linear}}$.
4. The differential equation $\left(\frac{dr}{ds}\right)^3 - r = 1$ is $\boxed{\text{first-order}}$ because the highest-order derivative is the first derivative. It has degree $\boxed{3}$ because the exponent of the first derivative is 3. Since the first derivative is not of degree 1, the differential equation is $\boxed{\text{nonlinear}}$.
5. For $y = e^x$, we have $\frac{dy}{dx} = e^x$ and $\frac{d^2y}{dx^2} = e^x$. Substitute these into the differential equation:

$$\begin{aligned}\frac{d^2y}{dx^2} - y &= 0 \\ e^x - e^x &= 0\end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

6. For $y = \frac{\ln x}{x^2}$, we have

$$\frac{dy}{dx} = \frac{x^2 \frac{1}{x} - \ln x (2x)}{x^4} = \frac{1 - 2 \ln x}{x^3}$$

and

$$\frac{d^2y}{dx^2} = \frac{x^3 \left(-2\frac{1}{x}\right) - (1 - 2 \ln x)(3x^2)}{x^6} = \frac{6 \ln x - 5}{x^4}$$

Substitute these into the differential equation:

$$\begin{aligned}
 \frac{d^2y}{dx^2} + \frac{5}{x} \frac{dy}{dx} + \frac{4}{x^2}y &= 0 \\
 \frac{6 \ln x - 5}{x^4} + \frac{5}{x} \frac{1 - 2 \ln x}{x^3} + \frac{4}{x^2} \frac{\ln x}{x^2} &= 0 \\
 \frac{6 \ln x - 5}{x^4} + \frac{5 - 10 \ln x}{x^4} + \frac{4 \ln x}{x^4} &= 0 \\
 \frac{6 \ln x - 5 + 5 - 10 \ln x + 4 \ln x}{x^4} &= 0 \\
 0 &= 0
 \end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

7. For $y = e^{-3x}$, we have $\frac{dy}{dx} = -3e^{-3x}$ and $\frac{d^2y}{dx^2} = 9e^{-3x}$. Substitute these into the differential equation:

$$\begin{aligned}
 \frac{d^2y}{dx^2} + 2 \frac{dy}{dx} - 3y &= 0 \\
 9e^{-3x} + 2(-3e^{-3x}) - 3e^{-3x} &= 0 \\
 9e^{-3x} - 6e^{-3x} - 3e^{-3x} &= 0 \\
 0 &= 0
 \end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

8. For $y = x^2 + 3x$, we have $\frac{dy}{dx} = 2x + 3$. Substitute these into the differential equation:

$$\begin{aligned}
 x \frac{dy}{dx} - y &= x^2 \\
 x(2x + 3) - (x^2 + 3x) &= x^2 \\
 2x^2 + 3x - x^2 - 3x &= x^2 \\
 x^2 &= x^2
 \end{aligned}$$

The function y satisfies the differential equation and so y is a solution.

9. $f(x, y) = x^3 + 2x^2y + 2xy^2 + y^3$ is a homogeneous function of degree 3, since

$$\begin{aligned}
 f(tx, ty) &= (tx)^3 + 2(tx)^2(ty) + 2(tx)(ty)^2 + (ty)^3 \\
 &= t^3x^3 + 2t^3x^2y + 2t^3xy^2 + t^3y^3 \\
 &= t^3(x^3 + 2x^2y + 2xy^2 + y^3) = t^3f(x, y) \quad \text{for all } t > 0
 \end{aligned}$$

10. $f(x, y) = x^2 - x^2y^2 + y^2$ is not a homogeneous function, since

$$f(tx, ty) = (tx)^2 - (tx)^2(ty)^2 + (ty)^2 = t^2(x^2 - t^2x^2y^2 + y^2) \neq t^k(x^2 - x^2y^2 + y^2)$$

for all $t > 0$ and some k .

11. $f(x, y) = xe^{y/x}$ is a homogeneous function of degree 1, since

$$\begin{aligned}
 f(tx, ty) &= (tx)e^{(ty)/(tx)} \\
 &= txe^{y/x} = tf(x, y) \quad \text{for all } t > 0
 \end{aligned}$$

12. $f(x, y) = \ln \frac{y}{x}$ is a homogeneous function of degree 0, since

$$\begin{aligned} f(tx, ty) &= \ln \frac{ty}{tx} \\ &= \ln \frac{y}{x} = t^0 f(x, y) \quad \text{for all } t > 0 \end{aligned}$$

13. (a) Express the differential equation

$$x(y^2 + 1) dx + y(x^2 - x) dy = 0$$

in the form

$$\begin{aligned} \frac{x}{x^2 - x} dx + \frac{y}{y^2 + 1} dy &= 0 \\ \frac{1}{x - 1} dx + \frac{y}{y^2 + 1} dy &= 0 \end{aligned}$$

The differential equation is separable.

- (b) Integrate the differential equation.

$$\begin{aligned} \int \frac{1}{x - 1} dx + \int \frac{y}{y^2 + 1} dy &= 0 \quad \text{Let } u = y^2 + 1. \\ \ln |x - 1| + \frac{1}{2} \ln(y^2 + 1) &= C_1 \\ 2 \ln |x - 1| + \ln(y^2 + 1) &= 2C_1 \\ \ln((x - 1)^2 + \ln(y^2 + 1)) &= 2C_1 \\ \ln[(x - 1)^2(y^2 + 1)] &= 2C_1 \\ (x - 1)^2(y^2 + 1) &= e^{2C_1} \\ (x - 1)^2(y^2 + 1) &= C \quad \text{Let } C = e^{2C_1} > 0. \\ y^2 + 1 &= \frac{C}{(x - 1)^2} \\ y^2 &= \frac{C}{(x - 1)^2} - 1 \\ y &= \pm \sqrt{\frac{C}{(x - 1)^2} - 1} \end{aligned}$$

where $C > 0$.

The general solution of the differential equation is

$$\boxed{y = \pm \sqrt{\frac{C}{(x - 1)^2} - 1}}$$

where $C > 0$ is a constant.

14. (a) Consider the differential equation $(2y + e^{2x}) dx + (2x + e^{2y}) dy = 0$. Let $M = 2y + e^{2x}$ and $N = 2x + e^{2y}$. Then

$$\frac{\partial M}{\partial y} = 2 \quad \text{and} \quad \frac{\partial N}{\partial x} = 2$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (2y + e^{2x}) dx = 2xy + \frac{1}{2}e^{2x} + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} \left[2xy + \frac{1}{2}e^{2x} + B(y) \right] = 2x + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 2x + \frac{\partial B}{\partial y} &= 2x + e^{2y} \\ \frac{\partial B}{\partial y} &= e^{2y} \end{aligned}$$

Now we integrate $\frac{dB}{dy} = e^{2y}$ with respect to y .

$$B(y) = \int e^{2y} dy = \frac{1}{2}e^{2y} + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = 2xy + \frac{1}{2}e^{2x} + \frac{1}{2}e^{2y} + C$$

The general solution of the differential equation is

$$\boxed{2xy + \frac{1}{2}e^{2x} + \frac{1}{2}e^{2y} + C = 0}$$

where C is a constant.

15. (a) Rewrite the differential equation $x \frac{dy}{dx} + y = x^6$ in the form

$$\frac{dy}{dx} + \frac{1}{x}y = x^5$$

to see that it is first-order linear. It is also exact.

- (b) Let $P(x) = \frac{1}{x}$. The integrating factor is

$$e^{\int P(x) dx} = e^{\int 1/x dx} = e^{\ln x} = x$$

Now multiply the differential equation by x and obtain

$$x \frac{dy}{dx} + y = x^6$$

The left side of the above equation is the derivative of xy , so we can write

$$\frac{d}{dx}(xy) = x^6$$

Integrate the equation above.

$$\begin{aligned} xy &= \int x^6 dx \\ xy &= \frac{1}{7}x^7 + C \\ y &= \frac{1}{7}x^6 + \frac{C}{x} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \frac{1}{7}x^6 + \frac{C}{x}}$$

where C is a constant.

16. (a) The differential equation

$$\frac{dy}{dx} - 2y = e^{3x}$$

is first-order linear.

- (b) Let $P(x) = -2$. The integrating factor is

$$e^{\int P(x) dx} = e^{-\int 2 dx} = e^{-2x}$$

Now multiply the differential equation by e^{-2x} and obtain

$$e^{-2x} \frac{dy}{dx} - 2e^{-2x}y = e^x$$

The left side of the above equation is the derivative of $e^{-2x}y$, so we can write

$$\frac{d}{dx} (e^{-2x}y) = e^x$$

Integrate the equation above.

$$\begin{aligned} e^{-2x}y &= \int e^x dx \\ e^{-2x}y &= e^x + C \\ y &= e^{3x} + Ce^{2x} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = e^{3x} + Ce^{2x}}$$

where C is a constant.

17. (a) Consider the differential equation $(2xy^3 + y^2 \cos x - 2x) dx + (3x^2y^2 + 2y \sin x) dy = 0$. Let $M = 2xy^3 + y^2 \cos x - 2x$ and $N = 3x^2y^2 + 2y \sin x$. Then

$$\frac{\partial M}{\partial y} = 6xy^2 + 2y \cos x \quad \text{and} \quad \frac{\partial N}{\partial x} = 6xy^2 + 2y \cos x$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and y , the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (2xy^3 + y^2 \cos x - 2x) dx = x^2 y^3 + y^2 \sin x - x^2 + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [x^2 y^3 + y^2 \sin x - x^2 + B(y)] = 3x^2 y^2 + 2y \sin x + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned} \frac{\partial f}{\partial y} &= N \\ 3x^2 y^2 + 2y \sin x + \frac{\partial B}{\partial y} &= 3x^2 y^2 + 2y \sin x \\ \frac{\partial B}{\partial y} &= 0 \end{aligned}$$

and then $B(y) = C$ is a constant. Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = x^2 y^3 + y^2 \sin x - x^2 + C$$

The general solution of the differential equation is

$$\boxed{x^2 y^3 + y^2 \sin x - x^2 + C = 0}$$

where C is a constant.

18. (a) Rewrite the differential equation $\frac{dy}{dx} + x^2 y - y = x^2 - 1$ in the form

$$\frac{dy}{dx} + (x^2 - 1)y = x^2 - 1$$

to see that it is first-order linear.

- (b) Let $P(x) = x^2 - 1$. The integrating factor is

$$e^{\int P(x) dx} = e^{\int x^2 - 1 dx} = e^{x^3/3 - x}$$

Now multiply the differential equation by $e^{x^3/3 - x}$ and obtain

$$e^{x^3/3 - x} \frac{dy}{dx} + (x^2 - 1)e^{x^3/3 - x} y = (x^2 - 1)e^{x^3/3 - x}$$

The left side of the above equation is the derivative of $e^{x^3/3 - x} y$, so we can write

$$\frac{d}{dx} (e^{x^3/3 - x} y) = (x^2 - 1)e^{x^3/3 - x}$$

Integrate the equation above.

$$\begin{aligned} e^{x^3/3 - x} y &= \int (x^2 - 1)e^{x^3/3 - x} dx \\ e^{x^3/3 - x} y &= e^{x^3/3 - x} + C \\ y &= 1 + C e^{-(x^3/3 - x)} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = 1 + C e^{-(x^3/3 - x)}}$$

where C is a constant.

19. (a) Express the differential equation

$$y \sin x \, dx - \cos x \, dy = 0$$

in the form

$$\begin{aligned}\frac{\sin x}{\cos x} \, dx - \frac{1}{y} \, dy &= 0 \\ \tan x \, dx - \frac{1}{y} \, dy &= 0\end{aligned}$$

The differential equation is separable. (It also happens to be exact.)

- (b) Integrate the differential equation.

$$\begin{aligned}\int \tan x \, dx - \int \frac{1}{y} \, dy &= 0 \\ \ln |\sec x| - \ln |y| &= C_1 \\ -\ln |\sec x| + \ln |y| &= -C_1 \\ \ln \left| \frac{y}{\sec x} \right| &= -C_1 \\ \left| \frac{y}{\sec x} \right| &= e^{-C_1} \\ \frac{y}{\sec x} &= \pm e^{-C_1} \\ \frac{y}{\sec x} &= C \quad \text{Let } C = \pm e^{-C_1} \\ y &= C \sec x\end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \frac{C}{\cos x}}$$

where C is a constant.

20. (a) Consider the differential equation $(2x \sin y - \ln y) \, dx + (x^2 \cos y - \frac{x}{y} + 3y^2) \, dy = 0$. Let $M = 2x \sin y - \ln y$ and $N = x^2 \cos y - \frac{x}{y} + 3y^2$. Then

$$\frac{\partial M}{\partial y} = 2x \cos y - \frac{1}{y} \cos x \quad \text{and} \quad \frac{\partial N}{\partial x} = 2x \cos y - \frac{1}{y}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$ for all x and $y > 0$, the differential equation is exact.

- (b) Find f by integrating $\frac{\partial f}{\partial x} = M$ partially with respect to x (holding y constant). Then

$$f(x, y) = \int (2x \sin y - \ln y) \, dx = x^2 \sin y - x \ln y + B(y)$$

where the constant of integration B is a function of y alone. Find $\frac{\partial f}{\partial y}$.

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y} [x^2 \sin y - x \ln y + B(y)] = x^2 \cos y - \frac{x}{y} + \frac{\partial B}{\partial y}$$

The function f satisfies $\frac{\partial f}{\partial y} = N$, so

$$\begin{aligned}\frac{\partial f}{\partial y} &= N \\ x^2 \cos y - \frac{x}{y} + \frac{\partial B}{\partial y} &= x^2 \cos y - \frac{x}{y} + 3y^2 \\ \frac{\partial B}{\partial y} &= 3y^2\end{aligned}$$

Now we integrate $\frac{dB}{dy} = 3y^2$ with respect to y .

$$B(y) = \int 3y^2 dy = y^3 + C$$

Substituting for $B(y)$ in the function $f(x, y)$, we obtain

$$f(x, y) = x^2 \sin y - x \ln y + y^3 + C$$

The general solution of the differential equation is

$$x^2 \sin y - x \ln y + y^3 + C = 0$$

where C is a constant.

21. (a) Both $x - y \tan \frac{y}{x}$ and $x \tan \frac{y}{x}$ are homogeneous of degree 1, so the differential equation is homogeneous.
 (b) Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}\left(x - y \tan \frac{y}{x}\right) dx + x \tan \frac{y}{x} dy &= 0 \\ \left(x - xv \tan \frac{xv}{x}\right) dx + x \tan \frac{xv}{x} (x dv + v dx) &= 0 \\ x dx + x^2 \tan v dv &= 0\end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^2 .

$$\begin{aligned}x dx + x^2 \tan v dv &= 0 \\ \frac{1}{x} dx + \tan v dv &= 0\end{aligned}$$

Integrate.

$$\begin{aligned}\int \frac{1}{x} dx + \int \tan v dv &= 0 \\ \ln |x| + \ln |\sec v| &= C_1 \\ \ln |x \sec v| &= C_1 \\ |x \sec v| &= e^{C_1} \\ x \sec v &= \pm e^{C_1} \\ \frac{x}{\cos v} &= \pm e^{C_1} \\ x &= \pm e^{C_1} \cos v \\ x &= \pm e^{C_1} \cos \left(\frac{y}{x}\right) \\ \pm \frac{x}{e^{C_1}} &= \cos \left(\frac{y}{x}\right) \\ Cx &= \cos \left(\frac{y}{x}\right) \quad \text{Let } C = \pm \frac{1}{e^{C_1}} \\ \cos^{-1}(Cx) &= \frac{y}{x} \\ x \cos^{-1}(Cx) &= y\end{aligned}$$

Then the general solution is $\boxed{y = x \cos^{-1}(Cx)}$, where C is a constant.

22. (a) Rewrite the differential equation $x \frac{dy}{dx} - 2y = x + 1$ in the form

$$\frac{dy}{dx} - \frac{2}{x}y = 1 + \frac{1}{x}$$

to see that it is $\boxed{\text{first-order linear}}$.

- (b) Let $P(x) = -\frac{2}{x}$. The integrating factor is

$$e^{\int P(x) dx} = e^{-\int 2/x dx} = e^{-2 \ln x} = e^{\ln(x^{-2})} = x^{-2}$$

Now multiply the differential equation by x^{-2} and obtain

$$x^{-2} \frac{dy}{dx} - 2x^{-3}y = x^{-2} + x^{-3}$$

The left side of the above equation is the derivative of $x^{-2}y$, so we can write

$$\frac{d}{dx} (x^{-2}y) = x^{-2} + x^{-3}$$

Integrate the equation above.

$$\begin{aligned} x^{-2}y &= \int (x^{-2} + x^{-3}) dx \\ x^{-2}y &= -x^{-1} - \frac{1}{2}x^{-2} + C \\ y &= -x - \frac{1}{2} + Cx^2 \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = Cx^2 - x - \frac{1}{2}}$$

where C is a constant.

23. (a) The differential equation

$$\frac{dy}{dx} + \frac{2}{x}y = \frac{y^3}{x^2}$$

is a $\boxed{\text{Bernoulli}}$ equation with $n = 3$.

- (b) Multiply the equation by y^{-3} to obtain

$$y^{-3} \frac{dy}{dx} + 2x^{-1}y^{-2} = x^{-2}$$

Let $v = y^{-2}$, so $\frac{dv}{dx} = -2y^{-3} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{1}{2} \frac{dv}{dx} + 2x^{-1}v &= x^{-2} \\ \frac{dv}{dx} - 4x^{-1}v &= -2x^{-2} \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{-4 \int x^{-1} dx} = e^{-4 \ln x} = e^{\ln x^{-4}} = x^{-4}$$

Now multiply the differential equation by x^{-4} and obtain

$$x^{-4} \frac{dv}{dx} - 4x^{-5}v = -2x^{-6}$$

The left side of the above equation is the derivative of $x^{-4}v$, so we can write

$$\frac{d}{dx}(x^{-4}v) = -2x^{-6}$$

Integrate the equation above.

$$\begin{aligned} x^{-4}v &= -\int 2x^{-6} dx \\ x^{-4}v &= \frac{2}{5}x^{-5} + C_1 \\ v &= \frac{2}{5}x^{-1} + C_1x^4 \end{aligned}$$

Using $v = y^{-2}$, rewrite the solution in terms of x and y .

$$\begin{aligned} y^{-2} &= \frac{2}{5}x^{-1} + C_1x^4 \\ y^2 &= \frac{1}{\frac{2}{5}x^{-1} + C_1x^4} \\ y^2 &= \frac{5x}{2 + 5C_1x^5} \\ y^2 &= \frac{5x}{2 + Cx^5} \quad \text{Let } C = 5C_1. \\ y &= \pm \sqrt{\frac{5x}{2 + Cx^5}} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \pm \sqrt{\frac{5x}{2 + Cx^5}}}$$

24. (a) The differential equation

$$\frac{dy}{dx} - 5y = -2y^2$$

is a Bernoulli equation with $n = 2$.

- (b) Multiply the equation by y^{-2} to obtain

$$y^{-2} \frac{dy}{dx} - 5y^{-1} = -2$$

Let $v = y^{-1}$, so $\frac{dv}{dx} = -y^{-2} \frac{dy}{dx}$, and substitute these into the equation above.

$$\begin{aligned} -\frac{dv}{dx} - 5v &= -2 \\ \frac{dv}{dx} + 5v &= 2 \end{aligned}$$

This is a first-order linear differential equation in x and v . The integrating factor is

$$e^{\int 5 dx} = e^{5x}$$

Now multiply the differential equation by e^{5x} and obtain

$$e^{5x} \frac{dv}{dx} + 5e^{5x} v = 2e^{5x}$$

The left side of the above equation is the derivative of $e^{5x}v$, so we can write

$$\frac{d}{dx} (e^{5x}v) = 2e^{5x}$$

Integrate the equation above.

$$\begin{aligned} e^{5x}v &= \int 2e^{5x} dx \\ e^{5x}v &= \frac{2}{5}e^{5x} + C \\ v &= \frac{2}{5} + Ce^{-5x} \end{aligned}$$

Using $v = y^{-1}$, rewrite the solution in terms of x and y .

$$\begin{aligned} y^{-1} &= \frac{2}{5} + Ce^{-5x} \\ y &= \frac{1}{\frac{2}{5} + Ce^{-5x}} \\ y &= \frac{5}{2 + Ce^{-5x}} \end{aligned}$$

The general solution of the differential equation is

$$\boxed{y = \frac{5}{2 + Ce^{-5x}}}$$

25. Rewrite the differential equation $x \frac{dy}{dx} + 2y = 6$ in the form

$$\frac{dy}{dx} + \frac{2}{x}y = \frac{6}{x}$$

to see that it is first-order linear. Let $P(x) = \frac{2}{x}$. The integrating factor is

$$e^{\int P(x) dx} = e^{\int 2/x dx} = e^{2 \ln x} = e^{\ln(x^2)} = x^2$$

Now multiply the differential equation by x^2 and obtain

$$x^2 \frac{dy}{dx} + 2xy = 6x$$

The left side of the above equation is the derivative of x^2y , so we can write

$$\frac{d}{dx} (x^2y) = 6x$$

Integrate the equation above.

$$\begin{aligned} x^2y &= \int 6x dx \\ x^2y &= 3x^2 + C \\ y &= 3 + \frac{C}{x^2} \end{aligned}$$

The general solution of the differential equation is $y = 3 + \frac{C}{x^2}$ where C is a constant. Let $x = 2$ and $y = 8$ to find C .

$$\begin{aligned} y &= 3 + \frac{C}{x^2} \\ 8 &= 3 + \frac{C}{2^2} \\ 5 &= \frac{C}{4} \\ 20 &= C \end{aligned}$$

The particular solution is

$$\boxed{y = 3 + \frac{20}{x^2}}$$

26. Both xy and $y^2 + x\sqrt{x^2 + y^2}$ are homogeneous of degree 2. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} xy dy &= (y^2 + x\sqrt{x^2 + y^2}) dx \\ x^2 v(x dv + v dx) &= (x^2 v^2 + x\sqrt{x^2 + x^2 v^2}) dx \\ -x^2 \sqrt{1 + v^2} dx + x^3 v dv &= 0 \quad (\text{when } x > 0) \end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^3 and $\sqrt{1 + v^2}$.

$$\begin{aligned} -x^2 \sqrt{1 + v^2} dx + x^3 v dv &= 0 \\ -\frac{1}{x} dx + \frac{v}{\sqrt{1 + v^2}} dv &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned} -\int \frac{1}{x} dx + \int \frac{v}{\sqrt{1 + v^2}} dv &= 0 \quad \text{Let } u = 1 + v^2. \\ -\ln|x| + \sqrt{1 + v^2} &= C \\ -\ln|x| + \sqrt{1 + \frac{y^2}{x^2}} &= C \end{aligned}$$

Use $x = 1$ and $y = 1$ to find C :

$$-\ln|1| + \sqrt{1 + \frac{1}{1}} = \sqrt{2} = C$$

Replace C with $\sqrt{2}$ in the equation.

$$\begin{aligned} -\ln|x| + \sqrt{1 + \frac{y^2}{x^2}} &= \sqrt{2} \\ \sqrt{1 + \frac{y^2}{x^2}} &= \sqrt{2} + \ln|x| \\ 1 + \frac{y^2}{x^2} &= (\sqrt{2} + \ln|x|)^2 \\ \frac{y^2}{x^2} &= (\sqrt{2} + \ln|x|)^2 - 1 \\ y^2 &= x^2 (\sqrt{2} + \ln|x|)^2 - x^2 \end{aligned}$$

Then the particular solution is $\boxed{y^2 = x^2 (\sqrt{2} + \ln|x|)^2 - x^2}$.

27. The differential equation

$$\frac{dy}{dx} + \frac{1}{x}y = 2$$

is first-order linear. Let $P(x) = \frac{1}{x}$. The integrating factor is

$$e^{\int P(x) dx} = e^{\int 1/x dx} = e^{\ln x} = x$$

Now multiply the differential equation by x and obtain

$$x \frac{dy}{dx} + y = 2x$$

The left side of the above equation is the derivative of xy , so we can write

$$\frac{d}{dx}(xy) = 2x$$

Integrate the equation above.

$$\begin{aligned} xy &= \int 2x dx \\ xy &= x^2 + C \\ y &= x + \frac{C}{x} \end{aligned}$$

Use $x = 1$ and $y = 0$ to find C : $0 = 1 + \frac{C}{1}$ so $C = -1$. The particular solution is

$$\boxed{y = x - \frac{1}{x}}$$

28. Both $x^2 + xy + y^2$ and $-x^2$ are homogeneous of degree 2, the differential equation $(x^2 + xy + y^2) dx - x^2 dy = 0$ is homogeneous. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned} (x^2 + xy + y^2) dx - x^2 dy &= 0 \\ (x^2 + x^2v + x^2v^2) dx - x^2(x dv + v dx) &= 0 \\ x^2(1 + v^2) dx - x^3 dv &= 0 \end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^3 and $1 + v^2$.

$$\begin{aligned} x^2(1 + v^2) dx - x^3 dv &= 0 \\ \frac{1}{x} dx - \frac{1}{1 + v^2} dv &= 0 \end{aligned}$$

Integrate.

$$\begin{aligned} \int \frac{1}{x} dx - \int \frac{1}{1 + v^2} dv &= 0 \\ \ln|x| - \tan^{-1} v &= C \\ \ln|x| - \tan^{-1} \left(\frac{y}{x} \right) &= C \end{aligned}$$

Use $x = 1$ and $y = 1$ to find C :

$$\ln|1| - \tan^{-1} \left(\frac{1}{1} \right) = C$$

so $C = -\frac{\pi}{4}$.

$$\begin{aligned}\ln|x| - \tan^{-1} \frac{y}{x} &= -\frac{\pi}{4} \\ \ln|x| + \frac{\pi}{4} &= \tan^{-1} \frac{y}{x} \\ \tan(\ln|x| + \frac{\pi}{4}) &= \frac{y}{x} \\ x \tan(\ln|x| + \frac{\pi}{4}) &= y\end{aligned}$$

Then the particular solution is $\boxed{y = x \tan(\ln|x| + \frac{\pi}{4})}$.

29. The differential equation is separable. Express the differential equation

$$\frac{dy}{dx} = \frac{y-1}{x+3}$$

in the form

$$\frac{1}{y-1} dy = \frac{1}{x+3} dx$$

Integrate the differential equation.

$$\begin{aligned}\int \frac{1}{y-1} dy &= \int \frac{1}{x+3} dx \\ \ln|y-1| &= \ln|x+3| + C_1 \\ |y-1| &= e^{\ln|x+3| + C_1} \\ |y-1| &= e^{\ln|x+3|} e^{C_1} \\ |y-1| &= |x+3| e^{C_1} \\ y-1 &= \pm(x+3)e^{C_1} \\ y-1 &= C(x+3) \quad \text{Let } C = \pm e^{C_1}. \\ y &= 1 + C(x+3)\end{aligned}$$

The general solution of the differential equation is $y = 1 + C(x+3)$. To find C , let $x = -1$ and $y = 0$. Then

$$\begin{aligned}y &= 1 + C(x+3) \\ 0 &= 1 + C(-1+3) \\ 0 &= 1 + 2C \\ -\frac{1}{2} &= C\end{aligned}$$

The particular solution is

$$\boxed{y = -\frac{1}{2}x - \frac{1}{2}}$$

30. The differential equation is separable. Express the differential equation

$$(1 - \cos x) \frac{dy}{dx} + y \sin x = 0$$

in the form

$$\frac{1}{y} dy + \frac{\sin x}{1 - \cos x} dx = 0$$

Integrate the differential equation.

$$\begin{aligned}
 \int \frac{1}{y} dy + \int \frac{\sin x}{1 - \cos x} dx &= 0 && \text{Let } u = 1 - \cos x. \\
 \ln |y| + \ln |1 - \cos x| &= C_1 \\
 \ln |y(1 - \cos x)| &= C_1 \\
 |y(1 - \cos x)| &= e^{C_1} \\
 y(1 - \cos x) &= \pm e^{C_1} \\
 y(1 - \cos x) &= C && \text{Let } C = \pm e^{C_1}. \\
 y &= \frac{C}{1 - \cos x}
 \end{aligned}$$

The general solution of the differential equation is $y = \frac{C}{1 - \cos x}$. To find C , let $x = \frac{\pi}{4}$ and $y = 1$. Then

$$\begin{aligned}
 y &= \frac{C}{1 - \cos x} \\
 1 &= \frac{C}{1 - \cos(\pi/4)} \\
 1 &= \frac{C}{1 - \frac{\sqrt{2}}{2}} \\
 1 - \frac{\sqrt{2}}{2} &= C
 \end{aligned}$$

The particular solution is

$$y = \frac{1 - \frac{\sqrt{2}}{2}}{1 - \cos x}$$

31. The differential equation

$$\frac{dy}{dx} - \frac{2}{x}y = x^2 \cos x$$

is first-order linear. Let $P(x) = -\frac{2}{x}$. The integrating factor is

$$e^{\int P(x) dx} = e^{-\int 2/x dx} = e^{-2 \ln x} = e^{\ln(x^{-2})} = x^{-2}$$

Now multiply the differential equation by x^{-2} and obtain

$$x^{-2} \frac{dy}{dx} - 2x^{-3}y = \cos x$$

The left side of the above equation is the derivative of $x^{-2}y$, so we can write

$$\frac{d}{dx} (x^{-2}y) = \cos x$$

Integrate the equation above.

$$\begin{aligned}
 x^{-2}y &= \int \cos x dx \\
 x^{-2}y &= \sin x + C \\
 y &= x^2(\sin x + C)
 \end{aligned}$$

The general solution of the differential equation is $y = x^2(\sin x + C)$ where C is a constant. Let $x = \frac{\pi}{2}$ and $y = 3$ to find C .

$$\begin{aligned} y &= x^2(\sin x + C) \\ 3 &= \frac{\pi^2}{4} \left(\sin \left(\frac{\pi}{2} \right) + C \right) \\ 3 &= \frac{\pi^2}{4} (1 + C) \\ \frac{12}{\pi^2} &= 1 + C \\ \frac{12}{\pi^2} - 1 &= C \end{aligned}$$

The particular solution is

$$y = x^2 \left(\sin x + \frac{12}{\pi^2} - 1 \right)$$

32. The differential equation is separable. Express the differential equation

$$\left(\frac{2x-1}{y} \right) dx + x \frac{1-x}{y^2} dy = 0$$

in the form

$$\left(\frac{2x-1}{x(1-x)} \right) dx + \frac{1}{y} dy = 0$$

Integrate the differential equation.

$$\begin{aligned} \int \left(\frac{2x-1}{x(1-x)} \right) dx + \int \frac{1}{y} dy &= 0 \\ \int \left(\frac{1}{1-x} - \frac{1}{x} \right) dx + \int \frac{1}{y} dy &= 0 \\ -\ln|1-x| - \ln|x| + \ln|y| &= C_1 \\ \ln \left| \frac{y}{x(1-x)} \right| &= C_1 \\ \left| \frac{y}{x(1-x)} \right| &= e^{C_1} \\ \frac{y}{x(1-x)} &= \pm e^{C_1} \\ \frac{y}{x(1-x)} &= C \quad \text{Let } C = \pm e^{C_1} \\ y &= Cx(1-x) \end{aligned}$$

The general solution of the differential equation is $y = Cx(1-x)$. To find C , let $x = -1$ and $y = 3$. Then

$$\begin{aligned} y &= Cx(1-x) \\ 3 &= C(-1)(1-(-1)) \\ 3 &= -2C \\ -\frac{3}{2} &= C \end{aligned}$$

The particular solution is

$$y = -\frac{3}{2}x(1-x)$$

33. Since $x^2 + y^2$ and $-xy$ are homogeneous of degree 2, the differential equation $(x^2 + y^2) dx - xy dy = 0$ is homogeneous. Let $y = xv$. Then $dy = x dv + v dx$. Substitute these into the differential equation:

$$\begin{aligned}(x^2 + y^2) dx - xy dy &= 0 \\(x^2 + x^2 v^2) dx - x^2 v(x dv + v dx) &= 0 \\x^2 dx - x^3 v dv &= 0\end{aligned}$$

For $x \neq 0$, we can separate the variables by dividing by x^3 .

$$\begin{aligned}x^2 dx - x^3 v dv &= 0 \\ \frac{1}{x} dx - v dv &= 0\end{aligned}$$

Integrate.

$$\begin{aligned}\int \frac{1}{x} dx - \int v dv &= 0 \\ \ln |x| - \frac{1}{2} v^2 &= C \\ \ln |x| - \frac{y^2}{2x^2} &= C \\ \ln |x| - \frac{y^2}{2x^2} &= -2 \quad (\text{since } y(1) = 2) \\ \ln |x| + 2 &= \frac{y^2}{2x^2} \\ 2x^2(\ln |x| + 2) &= y^2\end{aligned}$$

Then the particular solution is $y^2 = x^2(2 \ln |x| + 4)$, and when $x > 0$

$$\boxed{y = x\sqrt{4 + 2 \ln x}}$$

34. The differential equation is separable. Express the differential equation

$$y^2 \sin x dx + \left(\frac{1}{x} - \frac{y}{x} \right) dy = 0$$

in the form

$$x \sin x dx + \left(\frac{1}{y^2} - \frac{1}{y} \right) dy = 0$$

Integrate the differential equation.

$$\begin{aligned}\int x \sin x dx + \int \left(\frac{1}{y^2} - \frac{1}{y} \right) dy &= 0 \quad \text{Use } u = x \text{ and } dv = \sin x dx. \\ -x \cos x + \sin x - \frac{1}{y} - \ln |y| &= C\end{aligned}$$

The general solution of the differential equation is $-x \cos x + \sin x - \frac{1}{y} - \ln |y| = C$. To find C , let $x = \pi$ and $y = 1$. Then

$$\begin{aligned}-x \cos x + \sin x - \frac{1}{y} - \ln |y| &= C \\ -\pi \cos(\pi) + \sin(\pi) - \frac{1}{1} - \ln |1| &= C \\ \pi - 1 &= C\end{aligned}$$

The particular solution is

$$-x \cos x + \sin x - \frac{1}{y} - \ln |y| = \pi - 1$$

35. Assume that the solution of the differential equation $(x-2)y' + y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

Since $(x-2)y' + y = 0$, this leads to

$$\begin{aligned} (x-2) \sum_{k=1}^{\infty} k a_k x^{k-1} + \sum_{k=0}^{\infty} a_k x^k &= 0 \\ \sum_{k=1}^{\infty} k a_k x^k - \sum_{k=1}^{\infty} 2k a_k x^{k-1} + \sum_{k=0}^{\infty} a_k x^k &= 0 \end{aligned}$$

Change the index of summation in the power series on the first and third from k to $k-1$.

$$\begin{aligned} \sum_{k=2}^{\infty} (k-1) a_{k-1} x^{k-1} - \sum_{k=1}^{\infty} 2k a_k x^{k-1} + \sum_{k=1}^{\infty} a_{k-1} x^{k-1} &= 0 \\ \sum_{k=1}^{\infty} (k-1) a_{k-1} x^{k-1} - \sum_{k=1}^{\infty} 2k a_k x^{k-1} + \sum_{k=1}^{\infty} a_{k-1} x^{k-1} &= 0 \\ \sum_{k=1}^{\infty} [(k-1) a_{k-1} - 2k a_k + a_{k-1}] x^{k-1} &= 0 \\ \sum_{k=1}^{\infty} [k a_{k-1} - 2k a_k] x^{k-1} &= 0 \\ \sum_{k=1}^{\infty} [a_{k-1} - 2a_k] k x^{k-1} &= 0 \end{aligned}$$

(Notice that when $k=1$, the term $(k-1)a_{k-1}x^{k-1} = 0$ so the index of the first sum can change from 2 to 1.) Then $a_{n-1} - 2a_n = 0$ for $n \geq 1$, which can be written as

$$a_n = \frac{1}{2} a_{n-1}$$

Then

$$a_1 = \frac{1}{2} a_0 \quad a_2 = \frac{1}{2} a_1 = \frac{1}{2^2} a_0 \quad a_3 = \frac{1}{2} a_2 = \frac{1}{2^3} a_0 \quad a_4 = \frac{1}{2} a_3 = \frac{1}{2^4} a_0 \quad \cdots$$

The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= a_0 \sum_{k=0}^{\infty} \left(\frac{x}{2}\right)^k \end{aligned}$$

The power series representation of the general solution of the equation is

$$y(x) = a_0 \sum_{k=0}^{\infty} \left(\frac{x}{2}\right)^k$$

You may recognize the power series as geometric, in which case $y(x) = a_0 \frac{1}{1-x/2} = a_0 \frac{2}{2-x}$.

36. Assume that the solution of the differential equation $y'' + y' - 2y = 0$ can be expressed as the power series

$$y(x) = \sum_{k=0}^{\infty} a_k x^k$$

Then

$$y'(x) = \sum_{k=1}^{\infty} k a_k x^{k-1}$$

and

$$y''(x) = \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2}$$

Since $y'' + y' - 2y = 0$, this leads to

$$\sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=1}^{\infty} k a_k x^{k-1} - \sum_{k=0}^{\infty} 2 a_k x^k = 0$$

Change the indices of summation in the second and third power series so that x is raised to the $k-2$ power in each.

$$\begin{aligned} \sum_{k=2}^{\infty} k(k-1) a_k x^{k-2} + \sum_{k=2}^{\infty} (k-1) a_{k-1} x^{k-2} - \sum_{k=2}^{\infty} 2 a_{k-2} x^{k-2} &= 0 \\ \sum_{k=2}^{\infty} [k(k-1) a_k + (k-1) a_{k-1} - 2 a_{k-2}] x^{k-2} &= 0 \end{aligned}$$

Then $n(n-1)a_n + (n-1)a_{n-1} - 2a_{n-2} = 0$ for $n \geq 2$, which can be written as

$$a_n = -\frac{n-1}{n(n-1)} a_{n-1} + \frac{2}{n(n-1)} a_{n-2} = -\frac{1}{n} a_{n-1} + \frac{2}{n(n-1)} a_{n-2}$$

$$\begin{aligned} a_2 &= -\frac{1}{2} a_1 + \frac{2}{1 \cdot 2} a_0 = -\frac{1}{2} a_1 + a_0 \\ a_3 &= -\frac{1}{3} a_2 + \frac{2}{2 \cdot 3} a_1 = -\frac{1}{3} \left(-\frac{1}{2} a_1 + a_0 \right) + \frac{1}{3} a_1 \\ &= \frac{1}{2} a_1 - \frac{1}{3} a_0 \\ a_4 &= -\frac{1}{4} a_3 + \frac{2}{3 \cdot 4} a_2 = -\frac{1}{4} \left(\frac{1}{2} a_1 - \frac{1}{3} a_0 \right) + \frac{1}{6} \left(-\frac{1}{2} a_1 + a_0 \right) \\ &= -\frac{5}{24} a_1 + \frac{1}{4} a_0 \\ a_5 &= -\frac{1}{5} a_4 + \frac{2}{4 \cdot 5} a_3 = -\frac{1}{5} \left(-\frac{5}{24} a_1 + \frac{1}{4} a_0 \right) + \frac{1}{10} \left(\frac{1}{2} a_1 - \frac{1}{3} a_0 \right) \\ &= \frac{11}{120} a_1 - \frac{1}{12} a_0 \end{aligned}$$

The power series takes on the form

$$\begin{aligned} y(x) &= \sum_{k=0}^{\infty} a_k x^k \\ &= a_0 \left(1 + x^2 - \frac{1}{3}x^3 + \frac{1}{4}x^4 - \frac{1}{12}x^5 + \cdots \right) \\ &\quad + a_1 \left(x - \frac{1}{2}x^2 + \frac{1}{2}x^3 - \frac{5}{24}x^4 + \frac{11}{120}x^5 + \cdots \right) \end{aligned}$$

The power series representation of the general solution of the equation is

$$\begin{aligned} y(x) &= a_0 \left(1 + x^2 - \frac{1}{3}x^3 + \frac{1}{4}x^4 - \frac{1}{12}x^5 + \cdots \right) \\ &\quad + a_1 \left(x - \frac{1}{2}x^2 + \frac{1}{2}x^3 - \frac{5}{24}x^4 + \frac{11}{120}x^5 + \cdots \right) \end{aligned}$$

37. (a) Assume that the solution of the differential equation $y'' = -y \sin x$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \cdots$$

Substitute $x = 0$, $y(0) = 1$, and $y'(0) = 1$ into the differential equation to find $y''(0)$.

$$y''(0) = y(0) \sin(0) = 0$$

Now differentiate $y'' = -y \sin x$ with respect to x to find $y'''(0)$.

$$\begin{aligned} y''' &= -y' \sin x - y \cos x \\ y'''(0) &= -(1) \sin(0) - (1) \cos(0) = -1 \end{aligned}$$

Now differentiate $y''' = -y' \sin x - y \cos x$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned} y^{(4)} &= -y'' \sin x - y' \cos x - y' \cos x + y \sin x \\ y^{(4)} &= -y'' \sin x - 2y' \cos x + y \sin x \\ y^{(4)}(0) &= (0) \sin(0) - 2(1) \cos(0) + (1) \sin(0) = -2 \end{aligned}$$

Now differentiate $y^{(4)} = -y'' \sin x - 2y' \cos x + y \sin x$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned} y^{(5)} &= -y''' \sin x - y'' \cos x - 2y'' \cos x + 2y' \sin x + y' \sin x + y \cos x \\ y^{(5)} &= -y''' \sin x - 3y'' \cos x + 3y' \sin x + y \cos x \\ y^{(5)}(0) &= 1 \end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 + x - \frac{1}{3!}x^3 - \frac{2}{4!}x^4 + \frac{1}{5!}x^5 + \cdots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	1.0	1.0998	1.1985	1.2948	1.3873	1.4742	1.5538	1.6242	1.6833	1.7287	1.7583

38. (a) Assume that the solution of the differential equation $y'' = -e^x y' - y$ is given by the Maclaurin series

$$y(x) = y(0) + y'(0)x + \frac{y''(0)}{2!}x^2 + \frac{y'''(0)}{3!}x^3 + \frac{y^{(4)}(0)}{4!}x^4 + \dots$$

Substitute $x = 0$, $y(0) = 1$, and $y'(0) = 1$ into the differential equation to find $y''(0)$.

$$y''(0) = -e^0 y'(0) - y(0) = -2$$

Now differentiate $y'' = -e^x y' - y$ with respect to x to find $y'''(0)$.

$$\begin{aligned} y''' &= -e^x y'' - e^x y' - y' \\ y''' &= -e^x (y'' + y') - y' \\ y'''(0) &= -e^0 (-2 + 1) - 1 = 0 \end{aligned}$$

Now differentiate $y''' = -e^x (y'' + y') - y'$ with respect to x to find $y^{(4)}(0)$.

$$\begin{aligned} y^{(4)} &= -e^x (y''' + y'') - e^x (y'' + y') - y'' \\ y^{(4)} &= -e^x (y''' + 2y'' + y') - y'' \\ y^{(4)}(0) &= -e^0 (0 + 2(-2) + 1) - (-2) = 5 \end{aligned}$$

Now differentiate $y^{(4)} = -e^x (y''' + 2y'' + y') - y''$ with respect to x to find $y^{(5)}(0)$.

$$\begin{aligned} y^{(5)} &= -e^x (y^{(4)} + 2y''' + y'') - e^x (y''' + 2y'' + y') - y''' \\ y^{(5)} &= -e^x (y^{(4)} + 3y''' + 3y'' + y') - y''' \\ y^{(5)}(0) &= -e^0 (5 + 3(0) + 3(-2) + 1) - 0 = 0 \end{aligned}$$

Now differentiate $y^{(5)} = -e^x (y^{(4)} + 3y''' + 3y'' + y') - y'''$ with respect to x to find $y^{(6)}(0)$.

$$\begin{aligned} y^{(6)} &= -e^x (y^{(5)} + 3y^{(4)} + 3y''' + y'') - e^x (y^{(4)} + 3y''' + 3y'' + y') - y^{(4)} \\ y^{(6)} &= -e^x (y^{(5)} + 4y^{(4)} + 6y''' + 4y'' + y') - y^{(4)} \\ y^{(6)}(0) &= -e^0 (0 + 4(5) + 6(0) + 4(-2) + 1) - 5 = -18 \end{aligned}$$

The Maclaurin series then becomes

$$y(x) = 1 + x - \frac{2}{2!}x^2 + \frac{5}{4!}x^4 - \frac{18}{6!}x^6 + \dots$$

- (b) Construct a table that uses the first five nonzero terms of the series to approximate select values of y in the interval $0 \leq x \leq 1$.

x	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
y	1.0	1.0900	1.1603	1.2117	1.2452	1.2626	1.2658	1.2571	1.2388	1.2134	1.1833

39. Let $y(t)$ equal the number of bacteria at time t . The available food supply will support a maximum number M of bacteria, so the derivative $\frac{dy}{dt}$ is the rate of growth of the bacteria and is proportional to $M - y$, the difference between the maximum number and the number present. So

$$\frac{dy}{dt} = k(M - y)$$

where k is the constant of proportionality. Separate the variables and integrate the differential equation.

$$\begin{aligned}\frac{1}{M-y} dy &= k dt \\ \int \frac{1}{M-y} dy &= \int k dt \\ -\ln|M-y| &= kt + C_1 \\ \ln|M-y| &= -kt - C_1 \\ |M-y| &= e^{-kt-C_1} \\ |M-y| &= e^{-kt}e^{-C_1} \\ M-y &= \pm e^{-kt}e^{-C_1}\end{aligned}$$

Since C_1 is a constant, let $C = \pm e^{-C_1}$ where C is a constant. So $M-y = Ce^{-kt}$ and the number of bacteria as a function of time is

$$\boxed{y(t) = M - Ce^{-kt}}$$

40. Let $y = y(t)$ be the amount of chlorine in mg in the tank at time t . Chlorine enters the tank at the rate of $(2 \text{ mg/L})(100 \text{ L/min}) = 200 \text{ mg/min}$. The concentration of chlorine in mg/L is

$$\text{Concentration} = \frac{\text{amount of Cl}}{\text{number of L}} = \frac{y(t)}{1000 + (100 - 80)t} = \frac{y(t)}{1000 + 20t}$$

Then the rate at which the salt exits the tank is

$$\left(\frac{y(t)}{1000 + 20t} \text{ mg/L} \right) (80 \text{ L/min}) = \frac{80y(t)}{1000 + 20t} \text{ mg/min}$$

The mixture problem is modeled by the differential equation

$$\frac{dy}{dt} = \text{rate in} - \text{rate out} = 200 - \frac{80y}{1000 + 20t}$$

or

$$\frac{dy}{dt} + \frac{4}{50+t} y = 200$$

for $t \geq 0$. This equation is a first-order linear differential equation. The integrating factor is

$$e^{\int P(t) dt} = e^{\int 4/(50+t) dt} = e^{4 \ln(50+t)} = e^{\ln((50+t)^4)} = (50+t)^4$$

Multiply the differential equation by the integrating factor to obtain

$$\begin{aligned}(50+t)^4 \frac{dy}{dt} + 4(50+t)^3 y &= 200(50+t)^4 \\ \frac{d}{dt} [(50+t)^4 y] &= 200(50+t)^4\end{aligned}$$

Integrate both sides with respect to t .

$$\begin{aligned}(50+t)^4 y &= \int 200(50+t)^4 dt \\ (50+t)^4 y &= 40(50+t)^5 + C \\ y &= 40(50+t) + C(50+t)^{-4}\end{aligned}$$

The tank initially held 500mg of chlorine, so $y(0) = 500$, which we use to find C .

$$\begin{aligned}y(0) = 500 &= 40(50) + C(50)^{-4} \\ -1500 &= \frac{C}{6,250,000} \\ -9,375,000,000 &= C\end{aligned}$$

The amount of chlorine in g at time $t \geq 0$ is $y(t) = 40(50 + t) - 9,375,000,000(50 + t)^{-4}$. After 1 hour (60 minutes), there is $y(60) = 40(110) - 9,375,000,000(110)^{-4} \approx \boxed{4336 \text{ mg}}$ of chlorine in the tank.

41. Find y' by differentiating $xy = c$ with respect to x .

$$\begin{aligned} xy' + y &= 0 \\ xy' &= -y \\ y' &= -\frac{y}{x} \end{aligned}$$

Replace y' with $-\frac{1}{y'}$ to obtain the differential equation for the family of orthogonal trajectories.

$$y' = \frac{x}{y}$$

The differential equation $\frac{dy}{dx} = \frac{x}{y}$ is separable and can be written as

$$y \, dy = x \, dx$$

Integrate to find the general solution.

$$\begin{aligned} \int y \, dy &= \int x \, dx \\ \frac{1}{2}y^2 &= \frac{1}{2}x^2 + K_1 \\ y^2 &= x^2 + 2K_1 \end{aligned}$$

Since K_1 is a constant, we may write $K = 2K_1$, where K is a constant. The orthogonal trajectories for the family of hyperbolas $xy = c$ is the family of hyperbolas $y^2 - x^2 = K$. To find the particular curves needed for the graph, substitute $x = 2$ and $y = 3$ into $xy = c$ and $y^2 = x^2 + K$ separately and solve for c and K . The graph of $xy = 6$ and $y^2 - x^2 = 5$ is shown.

42. The spread of the rumor is modeled by logistic growth, so

$$y(t) = \frac{RM}{R + (M - R)e^{-kMt}}$$

models the function for $t \geq 0$ in hours. Rewrite this equation using $M = 100,000$ and $R = 10$:

$$\begin{aligned} y(t) &= \frac{(10)(100,000)}{10 + (100,000 - 10)e^{-100,000kt}} \\ &= \frac{1,000,000}{10 + 99,990e^{-100,000kt}} \end{aligned}$$

The number of people who have heard the rumor after 1 hour is 100. Use $y(1) = 100$ to find k .

$$\begin{aligned} 100 &= \frac{1,000,000}{10 + 99,990e^{-100,000k}} \\ 100(10 + 99,990e^{-100,000k}) &= 1,000,000 \\ 10 + 99,990e^{-100,000k} &= 10,000 \\ 99,990e^{-100,000k} &= 9990 \\ e^{-100,000k} &= \frac{111}{1111} \\ -100,000k &= \ln\left(\frac{111}{1111}\right) \\ k &= -\frac{\ln(111/1111)}{100,000} \end{aligned}$$

The number of people who have heard the rumor after t hours is modeled by

$$y(t) = \frac{1,000,000}{10 + 99,990e^{\ln(111/1111)t}}$$

To find how long it will take for 25% of the people to hear the rumor, solve $y(t) = 25,000$ for t .

$$\begin{aligned} 25,000 &= \frac{1,000,000}{10 + 99,990e^{\ln(111/1111)t}} \\ 25,000(10 + 99,990e^{\ln(111/1111)t}) &= 1,000,000 \\ 10 + 99,990e^{\ln(111/1111)t} &= 40 \\ 99,990e^{\ln(111/1111)t} &= 30 \\ e^{\ln(111/1111)t} &= \frac{1}{3333} \\ t \ln\left(\frac{111}{1111}\right) &= \ln\left(\frac{1}{3333}\right) \\ t &= \frac{\ln(1/3333)}{\ln(111/1111)} \approx 3.521 \end{aligned}$$

It will take about 3.5 hours for 25% of the people to hear the rumor.
